INTRODUCTORY NOTE.

In closing the Second Volume of the "Tropical Agriculturist," we have to direct attention to the increased amount of useful information afforded, and to the great variety of topics treated. From month to month we have endeavoured to lay before our readers the latest results of practical experience and scientific teaching in all that concerns tropical agriculture: and our ambition has been to make this periodical not only indispensable to the planter but of service to business men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge and science, besides being the basis of all human wealth. While directing our attention chiefly to the products most prominently mentioned on our title-page, we have never omitted to notice minor industries likely to fit in with tropical conditions; and our readers have an ample guarantee in the pages before them that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of common sense as well as of prolonged tropical experience in this the leading Crown and Planting Colony of the British Empire. A full and accurate Index affords the means of ready reference to every subject treated in this second volume which we now place in our subscribers' hands.

A. M. & J. FERGUSON.

PLANTING PROSPECTS IN CEYLON.

SHORT COFFEE CROPS AND THEIR EXPLANATION:—FALLING-OFF IN MANURING; LEAF DISEASE; GRUB; ABNORMAL SEASONS.

CINCHONA AND WHAT IT IS DOING FOR OUR COFFEE-PLANTERS.

TEA CULTIVATION AND THE SCARCITY OF CAPITAL.

UPPER MASKELIYA, 8th May 1882.

No comment has so far been offered on the letter of a Matale correspondent who endeavoured to shew, by his rainfall return during several blossoming seasons and the succeeding crops, that the weather this year could have little to do with the poor prospects for 1882-3. But I have no doubt a good deal could be said by planters of equal experience in other districts, to shew that, however applicable to his own corner of the land, our Matale friend's inferences could not be drawn from the figures and facts recorded elsewhere.

It is probably impossible to name any one cause in explanation of the disappointing coffee blossoming season just closed. For a good many years alternate crops (middling and short) have been the rule, and we find the first explanation of the paucity or absence of blossom in the fact that the current is regarded as the normally poor year. Alternate years of good and bad crops are usually experienced by cultivators of fruit trees all over the world, at least, when once their orchards, vineyards, coffee or cocoa gardens have passed their early years of luxuriance; but there can be no doubt that, in our own case in Ceylon, this alteroation has been intensified in a very striking way by other causes, of which the operation of the coffee leaf fungus is the most potent. As a consequence every alternate *pair* of years seem to shew a worse outturn than their predecessors. Here are the seasons and the export returns since 1874-75, when a maximum may be said to have been attained :—

Seasons.	*Exports.*	*Total.*
1874-5	... 968,694 cwt.	1,689,121
'75-6	... 720,427 ,,	
'76-7	... 943,047 ,,	1,563,339
'77-8	... 620,292 ,,	
'78-9	... 824,509 ,,	1,494,123
'79-80	... 669,614 ,,	
'80-81	... 453,758 ,,	1,353,758
'81-82	... 550,000 ,,	
'82-83 (conjectured)	... 350,000 ,,	

Doubtless objection will be taken in some quarters to the figures for the current season being put above 500,000 cwt., and for 1882-3 above 300,000; but the comparison is striking enough in shewing that the last *three* extraordinarily abnormal seasons in our table give a less aggregate than the *two* previous years. The alternation was slightly interfered with in 1879-80, when the crop was larger instead of smaller than in 1877-8. But this slight gain was woefully discounted in the succeeding year 1880-81, when not much more than one-half the outturn due was recorded, the fall being from 824,000 to 454,000 cwt. The present shipping season by our alternate rule is the one for a poor crop comparatively, but clearly, the pendulum having swung to so little purpose last year, while it is scarcely going to move at all for next crop, the exports of 1881-82 must be considered to be those of a comparatively "good" year. Alas! that the average export of coffee for the three seasons ending 30th September 1883 should not be shewn to exceed 450,000 cwt. against an average of 791,000 cwt. for the six years ending 30th Sept. 1880! The immense decline since 1880 is therefore the most notable feature in our table, and regarding the blossoming season of 1881 as an average one for the alternate poor year, those who think abnormal seasons have to do with our poverty of outturn must direct their attention to the blossoming seasons—Jan.-April—of 1880 and 1882 in order to explain the fall from 800,000 to 450,000 and two years later to 350,000 cwt. We believe an examination of the meteorological returns for the spring of 1880 and 1882, with the monthly average of from 5 to 10 years, will shew that, in the majority of our coffee districts, the rainfall more especially in the two critical months —February and March—has been much above the average. The figures for 1882 are not at hand to compare; but, taking typical estates and districts, we find, beginning at the south, that, in February and March 1880, the rainfall on Vegeria estate, Rakwana, was 22·23 inches against an average of 11·54 inches; on Deeside, Maskeliya, it was 23·15 against 12·15 inches; on Delrey, Dikoya, it was 21·38 against 11·29 inches; in Dimbula (at Craigie Lea, P. W. D. return) it was 15·88 against 4·52; on Ranghodde estate, Ramboda, it was 14·01 against 7·17 inches; on Leangwela, Maturata, the fall was 17·66 against 11·48 inches: on New Forest, Deltota, 13·83 against 7·76 inches. Going westward again, Templestowe, Ambagamuwa, gave 15·41 against 7·66 inches; Kabragalla, Dolosbage, 12·33 against 9·04; Pussellawa 13·17 contrasted with 8·10 inches; Kandy 8·96 against 6·25 inches. In the north, we find Kandenuwara estate, Matale, giving 20·76 against 8·50 inches; while Matale town gave 13·05 against 3·76; Leangolla, Madulkele, 10·67 against 7·44; Illagolla, Rangala, 9·81 against 8·36. Turning to the Uva districts, we have Wiharagalla estate, Haputale, giving 23·11 against 15·50 inches; Gowrakelle, Badulla, 18·41 against 11·38; Cocagalla, Hewa Eliya, 28·65 against 19·42; Bandarawela 15·99 against 7·99; and Diswella 18·98 against 6·12 inches. A similar return for February-March of the present year could not fail, we think, to present contrasts quite as striking. The lessons to be derived from them, practical men will readily understand.*

* Thus:—

	Total rainfall Feb. and March 1882.	
Place.	Feb. March.	
Vegeriya (Rakwana) ...	9·37 10·53	Ins.
Deeside (Maskeliya) ...	7·78 5·38	,,
Delrey (Dikoya) ...	5·77 8·92	,,
Ranghodde (Ramboda) ...	2·43 3·20	,,
Leangolla (Madukele) ...	7·04 5·28	,,
Templestowe (Ambagamuwa)	4·34 2·53	,,
Kandy ...	1·88 2·62	,,
Kandenuwara ...	3·75 5·35	,,
Illagolla (Rangala) ...	7·00 5·00	,,

No doubt, leaf-disease must be regarded as a chief cause of the steady falling-off revealed by our coffee crop figures. But, simultaneously with the depression and short crops experienced since 1878, we have had a less liberal system of cultivation—taking the country as a whole—and a large expanse of comparatively young coffee has not received that attention in manuring (and perhaps pruning) which was the rule in the previous decade and which proprietors would only be too glad to render, had they the means of investing in steamed bones, castor cake, or other similar valuable fertilizing substances.* A fair index to the quantity of artificial manure used is afforded in the returns of traffic : they run as follows :—

Manure carried by the Main Railway Line.

Years.	Tons.	Years.	Tons.
1868 ...	3,664	1875 ...	14,410
1869 ...	6,891	1876 ...	24,277
1870 ...	8,784	1877 ...	27,412
1871 ...	7,334	1878 ...	21,772
1872 ...	5,772	1879 ...	11,297
1873 ...	8,160	1880 ...	6,448
1874 ...	11,217	1881 ...	——(? 5,000)

Of course it cannot be denied that a great deal of money has been wasted, and that injury rather than benefit has resulted from the indiscriminate and thoughtless application of manures in past years ; but when we know of good old propreties which have been continuously treated for a score of years or so, giving, in such a season as the last and in spite of leaf disease, as much as 7 and 10 cwt. over fields of no inconsiderable area, it is impossible to deny the connection between judicious manuring and the amount of the coffee crop, whatever may be said of the season and of leaf-disease.

Still there are puzzling exceptions to almost every one of the rules of practise cherished by the most experienced of our planters, and never apparently were these more strikingly illustrated than during the past few seasons. When proceeding to England in July 1880, Mr. Giles F. Walker of Elbedde, Bogawantalawa (a gentleman who is second to none in the country in the careful attention he has paid to the weather and its bearing on crops), attributed a good deal of the disappointment attending two previous blossoming seasons in Dikoya to the absence of the continuously wet weather which usually prevailed right through crop-time, so enabling the trees to recover speedily and be ready for blossom. He expressed the hope then that wet weather from September to December might again be the rule. In 1880 this was not the case ; but last year the crop season was wet enough in all conscience. The rain continued all through December and on through January, and when some began to call "Hold, enough," there were other old hands who declared themselves more than satisfied, anticipating a hot dry March and April to make full compensation. That such has not been experienced is now generally admitted, and we believe in spite of our Matale correspondent that taking the country as a whole, had the rains stopped on the 15th February and dry weather proved the rule since then, instead of a crop of 300,000 cwt., we might fairly look for one of double that quantity. Still the anomalies reported in the experience of different districts are very curious. For instance a visiting agent, passing from Matale deluged with rain for weeks together in February and March this season, finds a blossom in danger of being burnt off in Kadugannawa for want of rain. Simultaneously we had recently a Dikoya planter expressing thankfulness that the rain had kept off for four days in contrast with the delight of his compeer in Hantane, over a day bringing heavy rain. Mr. G. D. Jamieson, who lately left Ceylon, on being asked about crop prospects in the district he had bid farewell to forever, said there was a good deal of blossom, more particularly *on pruned coffee* in Bogawantalawa and Dikoya, so far indicating the advantage of early pruning. But on the other side of the country we have a case where early pruning has destroyed the chance of crop. On Rangala properties, among the best cultivated in the country, after very satisfactory crops, the work was pushed on of clearing up and pruning in the full hope of another fair return from trees which, well-manured, had not suffered from carrying a good many cwts. per acre. But trees pruned early in January have since had nearly three months of growing weather, the rain moreover developing a fierce attack of leaf-disease, so that positively the only crop worth speaking of to be gathered during 1882-3, from the properties in question, will be from the fields unpruned in January and so far neglected ! Places always manured in the Knuckles and Kelebokka districts are giving no crop this season. How this may operate was well illustrated by the statement of Mr. Wm. Mackenzie in a previous season when rain fell freely throughout the blossoming season. At the beginning of the year in question, we remember his saying that the only district he considered to be quite ready for blossom was Dikoya ; but the trees which in January had 'wood' ready to burst into spike and flower, with some weeks of wet growing weather, lost their chance, and by the 1st March, the Dimbula coffee, which was bare two months earlier, had got ready, and so when the dry weather did come, the chance of Dikoya as a district was at an end ! So much for the influence of the weather. But at the same time there can be little doubt that in the pre-fungus days the coffee tree in good heart and well-clothed with vegetation did develope blossom, resist sudden changes of weather, and mature crop in a way not often experienced at the present time.

Nevertheless can it be truly said that our planters are worse off than agriculturists in other parts of

* Of the value of manure we had a satisfactory illustration the other day. "Look on that coffee and on this," said a planting friend: "see how the bushes there are full of blossom set, while here we have bare branches with incipient berries few and far between." The difference was certainly very striking, in the same soil, field and circumstances—the two strips adjoining each other: the only difference being that the one had been fed with bones and castor cake, while the other had got nothing. On the other hand a leading V. A. has often met our call for manure by bringing forward cases of estates giving as good returns without as others in the same district with manure. No doubt, for some seasons, such cases can be found, but who will dare say that the unmanured coffee, however favourably situated for climate and soil, will continue to maintain its good crops and reputation without manure?

the world ? We have had the troubles of British farmers brought prominently before us, and more recently there came a sad tale of distress from many parts of the Australian continent, the result of a terribly prolonged drought. Very noteworthy is it that there, as here, the "silver lining" to the dark cloud is found in the opportunity presented for cultivating "NEW PRODUCTS." The vignerons of France, the potato-cultivating Irish peasants, the wheat farmers of Australia, equally with the coffee planters of Ceylon, made the grand mistake of placing their sole dependence on one product. Let us listen to the comfort offered to the wheat farmers in South Australia in the Adelaide *Register* :—

[The extract which was to have been inserted here has unfortunately been mislaid by the writer: it reported, however, the great distress existing amongst the farmers of South Australia, many of whom had been absolutely ruined by the prolonged drought; a farmers' relief fund had been started at Adelaide; and the *Register* dwelt on the need for encouraging fruit culture to meet the case of dry years. Many large gardens and orchards had been planted, and establishments for preserving fruit for export were springing up about Adelaide.]

Would that the "rush" into new products in Ceylon had commenced ten years earlier; but surely, as it is, there is comfort for planters and capitalists in the indisputable facts already before the public. The Director of the Royal Botanic Gardens must be considered the very embodiment of caution and impartiality, and yet we are aware that the encouraging report he has made on the prospects of several new economic plants—notably on cinchona, cocoa, Liberian coffee and rubbers—expresses less than he feels about the importance of these industries. We feel sure that the omission of any reference to *tea* was not due to any want of interest in the extending cultivation of this most important product, nor to doubt of its success. Dr. Trimen, no doubt, considers our tea industry to have got beyond the experimental stage, while there was nothing about it calling for scientific criticism or remark. A glance at the export table is sufficient to shew how rapidly the figures for cinchona and tea are running up. Cardamoms also are making a decent display; but the exports of cocoa are rather "*lang o' comin*," no doubt due to the steady extension of the cultivated area. [In connection with our export trade generally, it is satisfactory to see that, though coconut oil has fallen off, coir yarn is being increasingly exported. as also plumbago, cinnamon bark and oil, citronella oil and some other minor products.]

The want of capital will alone prevent a good many thousands of acres being planted with tea this season: there are large expanses of coffee land which have yielded very poor returns of berries of late years, which offer great facility (and encouragement) to the planting with tea. Nowhere in these districts have I heard of tea bushes failing: everywhere this product seems to be flourishing luxuriantly. Surely the tea-plant ought to be suitable to our moist hot climate. Leafage rather than blossom and fruit distinguishes our natural vegetation; and if the old Indian tea planters in our midst are to be believed, nowhere in the opposite continent is so much encouragement offered to go into "tea" as in the Central Province of Ceylon. A great deal will be done in extending the area planted this year, now that good hybrid seed can be had for ten rupees per bushel; but this not so much in new clearings from forest reserves as in planting up fields and perhaps estates for which coffee has been found to be unsuitable. It behoves capitalists interested in coffee property to consider the advantage of adding tea as well as cinchona to the estate products. Few plantations are without patches, if not fields, which have never done and never will do much good in coffee and where it is equally useless to try the bark-tree, but for which tea seems well adapted. On badly grubbed coffee land, where cinchona cannot be got to grow, the tea-bush seems to luxuriate. We believe one of the most promising fields of tea in the country was, some years ago, the scene of abandoned, because completely grubbed-out, coffee. But alas! for tea, as cinchona and many other experiments full of promise, money is wanted, and that commodity is scarce in proportion to our coffee crops. It ought not to be so in respect of tea, if there is a steady profit of from R70 to R80 per acre to be made under the circumstances we refer to, counting the crop at 400 lb. and upwards per acre and the cost as equal to 40c. per lb. of tea f. o. b. at Colombo.

As regards cinchona cultivation in all its varied divisions and experiences, no one can say that, amidst many disappointments, there is not also much to encourage. Failures of plants and trees innumerable there have been, but nevertheless the value of the growing cinchonas at this moment must be very considerable, and if a large proportion of the succirubras are successfully utilized for the valuable "Ledgers" through the "Mattakelle" process, a very important addition to the wealth of the country must take place. As recent examples of success, encouraging enough to warrant still greater things from cinchona, the figures for the harvest gathering from an acre of red bark trees coppiced on an estate not a hundred miles distant, have been placed at our service :—

1,573 succirubra trees 6 to 7 years old, have given of

Good quill bark	... ...	5,890 lb.
Branch quill	... ...	1,055 ,,
Bottle-branch bark	... ...	2,269 ,,
Shavings	... ...	2,840 ,,
Root bark (of a few trees)	...	36 ,,
Total (as *dried* on the estate)		12,000 lb.

The pecuniary result is not yet made known, but probably this acre of land will give as much to the proprietor now as the rate paid and demanded for additional station accommodation on the extension line, while of course coppiced and shaven trees are ready to yield again in due season. In another case in Lower Dikoya, 2 acres of land useless for coffee, an eyesore, planted with cinchona which began to canker at three years old, gave bark of all kinds which yielded R700 in Colombo the other day.

Still more satisfactory perhaps is it to hear of Mr. Martin's experience on Nanuoya, where the shaving of an acre of succirubra trees, five years old, has given 1,400 lb of produce which has been sold (? valued) for R1,084. No doubt these are the exceptions. Mention could be made of dire

disappointment—large clearings laid bare by canker, or excess of moisture, or unsuitable soil, or, in some cases, from a cause mysterious enough to defy detection so far. Ninety per cent failures is a common experience in clearings, and the appearance of canker among the best trees after two, three, or four years is most discouraging. A West Haputale correspondent reports drainage as sufficient to check the dying-down of an officinalis clearing; but that will not do in all cases. The alternation of belts of blue gums, or tea-bushes, is likely to do better, and there can be no doubt that, as time rolls on, experience will render the cinchona industry far more satisfactory and stable than it is at present. In this connection it may be added that Mr. J. T. Rae's little peeling machine—the latest of several inventions—is described by those who have seen and used it as by far the cheapest (R25 to R30) and best yet made. At present, we believe Messrs. Walker & Greig of Dimbula and Dikoya cannot overtake the orders coming in for their Mr. Rae's invention. So it will be, we have no doubt, in respect of other products—in cultivation, harvesting and preparation, Ceylon men will be sure to improve steadily and to lead the rest of the tropical planting world.

GUTTA PERCHA (GUTTA TABAN, &c.).

(From the Encyclopædia Britannica, vol. xi.)

This name* is applied to the concreted or inspissated juice of various plants belonging to the natural order *Sapotaceæ*, growing in the Malay Peninsula. To what particular tree the name "gutta percha" properly belongs, there is no evidence to show; but it has been generally given to *Dichopsis Gutta* (Bentley and Trimen) or *Isonandra Gutta* (Hooker), the vernacular name of which is "taban."†

The *Dichopsis Gutta* attains a height of 60 to 80 feet, with a diameter of 2 to 4 feet. The leaves are obovate-oblong and entire, pale green on the upper side, and covered beneath with short reddish-brown shining down. The flowers are arranged in clusters of 3 or 4 in the axils of the leaves. The fruit, about an inch long, is of an ovoid shape, and is eaten by the Malays. In Siák (Sumatra) a vegetable butter is prepared from the seeds. The wood is soft, fibrous, spongy, of a pale colour, and marked with black lines, these being reservoirs of gutta percha.‡ The gutta, as it flows from the tree, is of greyish hue, occasionally with somewhat roseate tinge, probably, arising from the colour vessels of the bark becoming ruptured through surcharge, and their contents mixing with the gutta. This species does not furnish all the gutta percha of commerce; indeed there are other trees which yield larger quantities. In all there are about thirty varieties known; but some of the vernacular names in different districts may prove mere synonyms.

The geographical distribution of the trees producing gutta percha is very restricted. Gützlaff defines the limits as 6° N. and S. lat. and 100° to 120° E. long.; whilst Captain Lingard (who has great personal experience on the subject) gives the limits as 4° N. and 3° S. lat., still further restricting the finer varieties to 3° 50′ N. and 1° S., with a temperature ranging between 66° and 90° Fahr., and a very moist atmosphere. These limits are well within the isotherm of 80° Fahr. Many of the best varieties are found only on the hill slopes at a distance from the sea-coast, each variety forming a separate grove of from 200 to 500 trees, with high forest trees above them. They grow best in a rich light loam, with a rocky subsoil.

The collection of gutta percha generally takes place directly after the rainy season, as in the dry season the gutta does not flow so readily, while during the rains ague and jungle fever are most prevalent, and the gutta is liable to be washed away from the felled trees. The yield of a wellgrown tree of the best variety is from 2 to 3 lb. of gutta percha, such a tree being about thirty years old, 30 to 40 feet high, and 1½ to 3 feet in circumferenc A full-grown tree sometimes measures 100 to 140 feet to its first branches, with a girth of 20 feet at a distance of 14 feet from the base, and may yield 50 to 60 lb. of gutta percha, which loses in six months about 35 per cent. of its weight in drying.

The methods of extracting the gutta percha are much the same amongst the Malays, Chinese, and Dyaks. The trees are cut down just above the buttresses, or *banees*, as they are called; and for this purpose a staging about 14 to 16 feet high is erected. The tools used in felling are either "billiongs" or "parangs." A billiong is kind of axe used by the Malays in felling, building, &c. The blade is of chisel-like form and the tang is secured at right angles to a handle by means of a lashing of "ratan" or cane. The Chinese sometimes use an axe perfectly wedge-shaped. The parang looks more like a sword-bayonet, and in the hands of a Malay is a box of tools in itself, as with it he can cut up his food, fell a tree, build a house, or defend himself.

When the tree is felled the branches are speedily lopped off, to prevent the ascent of the gutta to the leaves. Narrow strips of bark, about an inch broad and 6 inches apart, are then removed, but not all round the tree, as its underpart in its fall becomes buried in the soft earth, much sap being thus lost. Some natves beat the bark with mallets to accelerate the flow of milk or gutta. The milk flows slowly (changing colour the while) and rapidly concretes, and, according to its source, may vary from yellowish-white to reddish or even brownish in hue. The gutta as it flows is received into hollow bamboos, doubled up leaves, spathes of palms, pieces of bark, cocoa-nut shells, or in holes scraped in the ground. If the quantity obtained is small, it is prepared on the spot by rubbing it together in the hands into a block, in one end of which a hole is made to carry it by. In this state it is known in the market as "raw gutta" or "gutta muntah." If water gets mixed with the juice, the gutta becouse stringy and is considered deteriorated, but after boiling appears quite as good. Sometimes the gutta is kept in a raw state for a month or two, and then undergoes the next step in the preparation, that is, boiling. The boiling is generally conducted in a "kwali" or pan of cast or hammered iron, of about 15 inches in diameter and 6 inches deep. The boiling is either simply with water, or with the addition of lime juice

* Gutta, or as it is variously written gutah, gatta, gittáh, gátta, is the Malayan term for gum, and Percha (pronounced as in perch, *not* hard as perka), accentuated variously as párcha, pertja, perchá, is the name of the tree; hence the term may be translated "gum of the percha tree." The old name of Sumatra was Pulo or Pulau Percha, *i.e.*, "island (Pulau) of the percha tree."

† Tubar, túban, tábán, is the name of the tree, and, according to Logan, a new word has been added to the Malay language, viz., Me·ábán (Men[t]aban), *i.e.*, to collect gutta taban. The greater number of Malay nouns admit of conversion into verbs by a prefix.

‡ For figures and botanical descriptions see *Lond. Journ. Bot.*, 1848; De Vriese, *De Handel in Getah-Percha*; and Bentley and Trimen's *Medicinal Plants*, part 35, p. 16 (1878).

or cocoa-nut oil. If one pint of lime juice, be added to three gallons of gutta juice, the latter coagulates immediately on ebullition.

On arriving at the port of shipment the gutta before, exportation, generally undergoes examination and classification into parcels, according to quality. As received in the "godowns" or warehouses it presentes great diversities in condition, shape, size, and colour, —from crumbling, hardly coherent, whitish or greyish "raw" or "getah muntah" fragments, to reddish or brownish blocks as hard as wood. Sometimes it is made up into all manner of grotesque shapes of animals, and it is nearly always largely adulterated with sago-flour, sawdust, clay, stones, &c. The Chinese are great adepts in assorting and classifying gutta, and frequently prepare from different varieties a certain "standard sample" by cutting or chopping the material into thin slices and boiling with water in large shallow iron pans, keeping the contents constantly stirred with poles, and adding good gutta percha and even cocoa-nut oil to give a better appearance. When sufficiently boiled the gutta is pressed into large moulds, and is then ready for shipment. This process of reboiling is wholly unnecessary, and in some cases is done only to get rid of stuff which has no right to be called "gutta percha."

The amount and value of gutta percha imported into Great Britain in 1875 77 were as follows :—

	1875.	1876.	1877.
Cwts.... ...	...19,686	21,558	26,359
Value... ...	£149,684	£163,441	£238,327

The price of gutta percha ranges from 4d. to 3s. per lb., according to quality and demand.

History.—The early history of the use of gutta percha is somewhat obscure; the Malays and Chinese are said to have long known and used it. One of the earliest notices of it in England occurs in a catalogue of the collection of the famous Tradescants.* Dr. Montgomerie, a surgeon in the East India Company's service, was the first to direct attention to gutta percha as likely to prove of great utility in the arts and manufactures. Having observed the substance in Singapore in 1822 in the form of whips, he commenced experimenting with it. In 1842, being again stationed at Singapore, he followed up the subject, and his recommendation of it to the medical board of Calcutta as useful for making of splints and other surgical apparatus met with high approval. He also sent specimens, with relative information, to the Society of Arts of London, which society warmly took up the subject, and on Montgomerie's return to England in 1844 presented him with its gold medal. Some have claimed the honour of introducing gutta percha to the notice of the commercial world for Dr. (afterwards Sir) José D'Almeida, who sent a specimen merely as a curiosity to the Royal Asiatic Society in 1843, but careful investigation clearly decides the question of priority in favour of Montgomerie. The Society of Arts having requested him to lay before them the result of his experiments, he delivered a lecture in the autumn of 1844, and many patents were at once taken out, the chief being those of Mr. C. Hancock, Mr. Nickels, Mr. Keene, Messrs. Barlow and Forster, Mr. E. W. Siemens, and other. After this the substance soon came into general use. *

Properties.—Gutta percha, like many other milky juices, occurs in the lactiferous tissue of the plant, which exists in greatest abundance in the middle layer of the bark. See BOTANY, vol. iv. p. 87.

Gutta percha is resolvable into two resins, *albin* and *fluavil*. Like caoutchouc or india rubber, it is a hydrocarbon; Soubeiran gives its composition as —carbon 87·80 and hydrogen 12 20. In commercial gutta percha we have this hydrocarbon or pure gutta, *plus* a soft resin, a resultant of oxidation of the hydrocarbon. M. Payen gives the following analysis of commercial gutta percha :—

Pure gutta (milk-white in colour and fusible), 75 to 82 per cent.

Resins soluble in boiling alcohol :—

1. Crystalbin or albin ($C_{20}H_{32}O_2$), white, and crystallizing out of the alcohol as it cools, 6 to 14 per cent.

2. Fluavil $C_{20}H_{32}O$), yellow, falling as an amorphous powder on the cooling of the alcohol, 6 to 14 per cent.

It is thus apparent that the change of pure gutta into a resin-like mass takes place naturally if means be not taken to stop it. Many a good parcel has been thus lost to commerce, and the only remedy seems to be thorough boiling as soon after collecting as possible. It must be remembered too that, in cutting through the bark to arrive at the laticiferous vessels, many other vessels and cells become ruptured, containing tannic and gallic acids, &c., and the presence of these no doubt accelerates oxidation. In opening bottles of the milky juice a turbidity and effervescence are often noticed, owing to the formation of a brownish liquid, the colour being probably due to the presence of gallic acid. In improperly prepared blocks of gutta also, these foreign substances induce the presence of a brown fermented and putrid liquid which decomposes the internal mass. Many of these substances, being soluble in water, are removable by the process of boiling.

Gutta percha as met with in commerce is of a reddish or yellowish hue, but when quite pure is of a greyish-white colour. In this state it is nearly as hard as wood, only just receiving the impression of the nail, is of a porous structure, and when viewed under the microscope has the appearence of a series of variously hued prisms. When moulded, rolled into sheets, or drawn into ropes, it assumes a fibrous character in the direction of its greatest length, in which direction consequently it can be stretched without rupture. If however, a strip of a sheet be cut off across the fibre, it will be found that a redistribution of the tenacity of the slip takes place; *i. e.* the direction of the fibrous character is developed in an opposite direction. The electrical properties of gutta percha were first noticed by Faraday. If a piece be subjected to friction, an electric spark can be obtained. On its relative electric conductivity, see vol. viii p. 53.

At a temperature of 32° to 77° Fahr., gutta percha has as much tenacity as thick leather, though inelastic and less flexible. In water at 110° Fahr. it becomes less hard; towards 120° Fah. it becomes doughy, though still tough; and at from 145° to 150° it grows soft and pliable, allowing readily of being rolled and moulded. In this state it has all the elasticity of

* In the *Museum Tradescantianum*; or, *a Collection of Rarities preserved at south Lambeth, near London, by John Tradescant*, . . . London, MDCLVI., the following entry occurs (p. 44) :—"VIII, Variety of Rarities.—The plyable mazer wood, being warmed, will work to any form." This museum became the nucleus of the Ashmolean Museum at Oxford. The word "mazer," variously spelt, often occurs in early English poetry, and is specially mentioned in old catalogues and wills. It is by no means impossible that mazer cups may have been made of gutta percha, as its lightness, strength, and non-liability to fracture would recommend it; and curiously enough one of the vernacular names of the tree yielding gutta percha is "mazer wood tree."

* See Collins on "Gutta Percha" in *British Manufacturing Industries* (Stanford & Co.), and the very interesting volume of *Specifications* of *Patents in Caoutchouc, Gutta Percha*, &c., issued by the Patent Office.

caoutchouc, but this it loses as it cools, gradually becoming hard and rigid again, and retaining any form impressed on it whilst in its plastic condition. It is highly inflammable, and burns with a bright flame, dropping a black residue like sealing wax. The specific gravity of gutta percha has been variously stated at from 0·96285 to 0·99923. It is insoluble in water, alcohol, dilute acids, and alkalies, but dissolves in warm oil of turpentine, bisulphide of carbon, coal tar oil, caoutchin or oil of caoutchin, and its own oil—for it yields by destructive distillation an oil similar to that yielded by caoutchouc under the same treatment. Ether and some of the essential oils render it pasty, and it is softened by hot water, absorbing a small quantity of the water, which is slowly parted with in cooling.

Manufacture and Applications.—Gutta percha, as received in England, is in irregular clumps or blocks, and is frequently adulterated with massive stones, sawdust, bark, sago flour, and other foreign matters; and the first step in its manufacture is to cleanse it thoroughly. The blocks are first sliced by means of a powerful circular wheel driven by machinery, and having fixed in it two or three strong chisel-like knives, by which it is divided into thin slices. These are placed in wooden troughs filled with water and heated by steam. As soon as the gutta percha becomes soft it is taken out in baskets and placed in a toothed iron cylinder, called a "devilling" machine, which tears it into fragments; these fall into a trough of water, and the impurities sink to the bottom, leaving the purified gutta floating in the form of a spongy mass. This mass is then taken out by means of perforated shovels, thoroughly washed in cool water, and dried in baskets. It is then packed in jacketed iron chests heated by steam, and left till it becomes soft, when it is at once removed, and kneaded or masticated by means of a cast-iron cylinder, with a movable lid and an internal revolving toothed iron axis—the result being a homogeneous dough-like reddish-brown mass. Sometimes various substances are introduced into this machine, which is called a "masticator," to increase the hardness or density of the gutta, or to colour it—such as orange or red lead, chrome, vermilion, yellow ochre, sulphur, caoutchouc, gypsum, or resin, care being taken to use such substances only as are not affected by the heat necessary in the operation. The incorporation is conducted with great nicety, as, at the will of the operator, a soft and elastic or a hard and horny substance can be produced. When sufficiently masticated, the gutta is placed whilst still hot between two steel cylinders, and thoroughly rolled. By means of an endless band of felt the gutta is returned again to the cylinders, the distance between which is gradually diminished so as to compress and completely drive out any contained air from the gutta percha. There are various machines for cutting, driving bands, &c., to a uniform width, and for rounding off the edges and finishing. Soles for boots are made by cutting a long strip of the requisite width, and then passing the strip under a hollow die.

In making piping a machine is used consisting of a cylinder, with a diepiece attached of the requisite size. By means of a piston the gutta percha, which is introduced into the cylinder in a plastic condition, is driven through the die-piece, and the piston gives the inner diameter of the piping. As the piping issues from the machine, it passes immediately into a trough of water, which "sets" it and prevents it from collapsing. The value of gutta percha piping is very great: it does not contaminate water as lead piping does; it withstands insects, damp, &c., and is easily manipulated, being shortened, lengthened, or repaired without trouble or expense; and its acoustic properties have led to its employment largely in the manufacture of aural, stethoscopical, and other instruments. Gutta percha speaking-tubes are now to be seen in nearly every office. The substance too, from the fact that few acids and alkalies affect it, especially if dilute, is largely employed for funnels, siphons, and other chemical apparatus.

In telegraphy gutta percha is of the very highest importance, being a cheap, lasting, and powerful insulator, easily applied to telegraphic wires. The general method of coating telegraphic wire is by charging a cylinder with plastic gutta percha, and forcing it through a die-piece, the wire forming a central core. As the wire is drawn through this "die" or "moulding" piece, it becomes coated to the requisite thickness, and, after passing through water, it is wound on drums ready to be coated with tarred rope, and with galvanized iron wire if required for submarine cables.

The readiness with which gutta percha, whilst in its plastic condition, receives an impression, which it retains when cold, early led to its employment in the decorative and fine arts, since it reproduces the finest lines, as in the taking of moulds from electrotypes. See Electrometallurgy.

In the production of imitations of oak and other ornamental woods, gutta percha has been largely used, since by the admixture of various substances "graining" or "marbling" can be very naturally represented, and a coating of a solution of gutta percha gives a varnish of great brilliancy.

Substitutes.—Many substances have been recommended as substitutes for or as supplementary to, gutta percha. Among these Balata gum undoubtedly holds the first place. It is obtained from the *Mimusops Balata* (Gartner), a tree found in British and French Guiana, Jamaica, &c. Prof. Bleekrod seems to have been the first to direct attention to this substance, by bringing it before the notice of the Society of Arts in 1857. The Balata gum combines in some degree the elasticity of caoutchouc with the ductility of gutta percha, freely softening and becoming plastic, and being easily moulded like gutta percha. What small parcels have been sent to England have met with a ready sale, and were remarkably pure and free from adulteration. But unfortunately, through the difficulty of collection, the occupation being dangerous and unhealthy, the supply of this excellent article has fallen off. It is procured by making incisions in the bark of the tree about 7 feet from the ground, a ring of clay being placed around to catch the milk as it exudes. A large tree is said to yield as much as 45 lb of "dry gum." *Pauchontee*, the produce of *Dichopsis elliptica*, Collins (*Bassia elliptica*, Dalzell), is a most interesting substance, and may yet prove an article of commerce if properly treated; at present, although by heat it becomes plastic and ductile, it is brittle and resin-like when cold. The tree is found very generally distributed in Wynaad, Coorg, Travancore, &c.

Many of the euphorbias yield milky juices which have some at least of the properties of gutta percha. The chief amongst these are the cattimandoo (*Euphorbia Cattimandoo*, Elliot) and the Indian spurge tree (*E. Tirucalli* Linn.) of India, and some euphorbias at the Cape of Good Hope. The alstonia or pala gum (*Alstonia scholaris*, R. Br.) and the mudar gum (*Calatropis-gigantea*, R. Br.), have also been recommended as substitutes for gutta percha. But the attempts made to utilize these substances have as yet been unsuccessful.

Future Supplies.—A very important matter for consideration is the question of the future supplies of gutta percha. It is after all only a spontaneous natural product. If a Malay or Chinese wishes to plant pepper, gambier, &c., he burns down a portion of the forest, and, when he has raised two or three

crops, he clears a new portion, and thus finely wooded spots become denuded of trees, and covered with rank grass rendering them unfit for further cultivation. Again, to obtain the gutta percha the trees are cut down and none are planted in their stead, so that in districts where they were in abundance one or two only are now preserved as curiosities. It is a wonder indeed that a single tree is left. A writer in the *Sarawak Gazette* says that from 1854 to 1875 over 90,000 piculs (of 133⅓ lb each) of gutta percha was exported from Sarawak alone, and this meant the death of at least 3,000,000 trees. In fact the only thing that preserves the tree at all is that it is of no use to cut one down till it is 25 to 30 years old. Sooner or later recourse must be had to cultivation and conservation. (J. Co.)

MANURING, WEEDING, &c.

A correspondent writes:—

The *Field* of March 25th contains a lecture on "the production and loss of nitrates" by Mr. Warington that might interest many of your readers, the subject being one that more than probably is deserving of serious attention here, as at home, under many headings. Not least so as regards manuring, unremitted clean weeding, and the system so largely in vogue of close surface draining, *to an orthodox depth of not under* 18 *inches*! I mean to say nothing against either of the above, though, as regards the system of draining, I have often *fancied* coffee at least did not benefit by a too close adherence to the latter; and that shallower drains, and as few of them as possible, answered best. As for manuring: nothing like it to secure good crops, and high returns, of course! But still there are two ways of doing a thing; and much hitherto unaccountable want of success under this heading may now become explained.

Systematic clean weeding is of course such an immense saving and convenience in many ways that counter arguments would need be grave to think even of foregoing it. Still it may have its disadvantages, and seriously impoverishing ones too!

The same paper also contains an interesting account of the sugar sorghum enterprise in the United States. Also, a letter from Mr. Morris, which, as I read it, is nothing better than an attempt to recruit capital and investors at home, for Jamaica, at the expense of Ceylon, by a disparaging and unjustifiably incorrect comparison and statement as regards the labor supplies of the two countries.

Have blue gum leaves or a decoction of same; chloride of lime; margosa oil; carbolic powder; castor oil varnish, or crab oil, only, it is said in the *Field*, procurable in Demerara, received fair trial against white ants?

X.

P. S.—I cannot help fancying that rather coarse, broken, dry charcoal might supply a useful medium for applying strong preventatives that otherwise would be injurious to the plant. If, as I fancy in the case of ammonia, it has the property of absorbing, and subsequently releasing, but very slowly, any at all volatile substance, it might do this *so gradually* as to in no way harm the plant, though to a sufficient extent to appeal to the good sense of the ants and induce them to pass on; whilst at the same time it would store a supply sufficient to act as a reminder for an indefinite time.

THE CLIMATE OF MYSORE.

At the close of a very interesting article in the *Madras Mail* on sun spots and their coincidence with heavy or light rainfall and famine, the climate of Mysore is thus noticed:—

In Mysore there is no rain in the so-called cold weather, and naturally there are no cold weather crops. The average rainfall for the five months from the 31st November to the 31st April is only 3⅛ inches, and this figure, small as it is, represents only fitful tropical showers, which dry up at once under a burning almost vertical sun and the parching winds of that season, acting too on a plateau 2,000 and 3,000 feet above the sea; for it must be remembered that evaporation proceeds more rapidly in a rare atmosphere. Under these conditions agriculture is as impossible as under the rigours of a Canadian winter. For the space of five months the land has rest. The average rainfall for May is four inches, but this is derived from cyclonic falls and years when the monsoon sets in, as it does sometimes, as much as a month earlier than usual. The ryot looks for thunder showers to plough his fields towards the end of May, but practically the 1st of June marks the opening of the agricultural year in Mysore. The dry N. E. wind is replaced by the moist S. W. wind, merciful clouds temper the sun, the thermometer drops ten degrees, and nature awakens from the sleep of the dry season. This is the seed time of the year, and any deficiency of rainfall in the scanty monthly four inches of that period becomes serious at once. Of wet cultivation, there is not much carried on in Mysore under the disadvantages of the dry season. That under river-fed channels is comparatively of insignificant area; that under tanks is very restricted, and depends on the supply of water in the tank, *i. e.*, on the quantity rather than the quality of the last monsoon rainfall. A cultivator of wet land has his eye on his tank, as he puts his plough through the sludge. He will plough just as much as he thinks he has water for. The fitful showers of the dry season are a matter of indifference to him. These showers will put no water into his tank, and, when it is considered that the evaporation from sheets of water freely exposed is about two-thirds of an inch per diem in the dry weather, we arrive at the result that the total average dry season rainfall would normally equal, area for area, the evaporation from a rice flat for four days. Practically, therefore, these hot weather showers are of no account to the cultivator; and, when the cry of famine in Mysore is raised in the middle of the hot weather, it will be admitted that the moment chosen is singularly ill-timed. We have seen that there was last year a small deficiency in the S. W. monsoon; the N. E. was up to the average; there were two periods of anxiety owing to two stoppages of the rains, the first of practically a month's duration in July, the second of three weeks in October, normally the wettest month of the year. But the year shows a total of 27½ inches of otherwise fairly distributed rainfall, against the average of 35 inches (35·59 if the average of the last 11 years be taken), and in the face of such a record, there does not seem much chance of a famine. The years 1871 and 1873 had rainfalls each of 29 inches, and no one cried famine, although the population of Mysore was then one-sixth greater than now. Men's minds are still unhinged by the remembrance of the fearful calamities of 1876. The early showers are deficient: there is a slight importation of ragi by rail, as is most natural considering the harvests in the surrounding districts of Madras were better than those in Mysore, and forthwith the cry of "wolf" is raised. The fact is we know less about the periodicity of droughts in Mysore, a country which has been known to Europeans for a century, than in the newly settled districts of inland Australia, where the droughts are of great severity, but are considerably mitigated by a knowledge of their periods of recurrence.

COFFEE.

We make no apology for once more calling the attention of our readers to the importance of ensuring that coffee supplied to the public shall be genuine, and we are pleased to find that this matter is attracting the attention of members of the House of Commons, and that Sir E. Lechmere on Monday night, in putting a question as to the Treasury minute of January 20th, and the encouragement held out thereby to professional adulteration of coffee, put the saddle on the right horse, and directed his inquiry to the Right Hon. Joseph Chamberlain. In the very able speech which the President of the Board of Trade made in the late debate on Free Trade he stated that, whereas the consumption of articles of luxury, and notably tea and cocoa, had steadily increased, the consumption of coffee had undergone a decrease. The right hon. gentleman, with a surprising *naïveté*, stated that he was unable to account for this—"possibly the public taste had changed." Now, one cannot possibly believe that the taste for what passes for coffee has decreased. The preachings of the temperance party and the fact that "coffee palaces" have been established by thousands throughout the country point in another direction, and the success of private traders and public companies in palming off mixtures makes it very certain that the consumption of drinks which are flattered by the name of coffee has undergone an enormous increase. If Mr. Chamberlain wishes to know why the consumption of coffee has decreased, we must refer him to our annotation of March 25th, by which he will find that, out of thirty-seven samples of coffee bought in London during the month of February 1882, only two were genuine, and that not a few contained as little as 10 per cent. of true coffee. It is idle to contend, as Mr. Chamberlain did in his answer to Sir E. Lechmere, that the recent Treasury minute does not tend to increase the practice of adulteration: for facts are strikingly against him; and if this obnoxious minute be not cancelled, Mr. Chamberlain must rest under the imputation of giving the assistance of the Board of Trade to unprincipled traders. Why should the importation of mixtures of coffee with chicory, "and any other vegetable matter," be encouraged, and of what use is it to the public? Surely those who prefer their coffee mixed can mix it for themselves. In these days of "bold advertisement" every tradesman ought to be compelled not only to sell mixtures as such, but to give on each packet an exact statement of the nature of the mixture and its percentage composition. When this is done there will, perhaps, be an end of the outrageous cheating which takes place in connexion not only with coffee, but with hundreds of "patent" foods bearing incomprehensible names. Coffee may be looked upon as a home product, being largely produced in the British Empire, and, although we do not ask for "protection" for our countrymen from any legitimate competition, we think they have a right to demand that the Government shall at least ensure that those who import roasted vegetable refuse and sell it as coffee shall at least be made to pay dearly for the privileges which the Board of Trade allows to them. Coffee unroasted and raw pays a duty of 2d. per lb. If imported mixtures were saddled with a duty of sixpence, the importation of chicory and other (valuable?) vegetable matters unmixed would not be hindered, the British public would be able to get these mixtures more cheaply than at present (because the profit of the dishonest trader would be lessened), and a genuine and proper protection would be afforded to our countrymen who have invested their capital in coffee plantations. Coffee is a stimulant and possesses stimulating properties which chicory and roasted cabbage stumps do not, and we feel sure that, until the working man is made to understand the stimulating value of coffee, and is enabled to feel that a jaded nervous system is more benefited by an infusion of the coffee berry than by a glass of gin, the temperance movement will take no firm hold of the population. Those who seek for stimulation from coffee should buy it raw and roast it and grind it for themselves.—*Lancet.*

NO REWARD FOR A REMEDY FOR LEAF-DISEASE.

The following correspondence has been forwarded to us by the Secretary to the Planters' Association of Ceylon:—

Colonial Secretary's Office, Colombo, 8th May 1882.

Sir,—I am directed by the Governor to transmit for the information of the Planters' Association the accompanying copy of a despatch and of its enclosure from the Secretary of State for the Colonies.—I am, sir, your obedient servant, (Sigd.) J. A. SWETTENHAM,
For Colonial Secretary.

The Secretary, Planters' Association, Kandy.

Downing Street, 4th April 1882.

Sir,—I caused your despatch No. 75 of the 15th Feb., suggesting that a reward should be offered for the discovery of a remedy for the coffee leaf-disease, to be referred to Sir J. Hooker, for an expression of his opinion, and I now have to enclose a copy of his reply.

3. I agree with Sir Joseph Hooker and with Dr. Trimen that no advantage would result from the offer of such a reward, but that, on the contrary, it would encourage false hopes, and might possibly lead to considerable inconvenience. I do not therefore feel able to sanction either the offer of a reward or the grant of pecuniary assistance to experiments in connection with the coffee disease.—I have &c., (Sigd.) KIMBERLEY.

Governor Sir J. R. Longden, K.C.M.G.

Royal Gardens Kew, March, 22nd 1882.

SIR,—I am directed by Sir Joseph Hooker to acknowledge the receipt of your letter of March 21st requesting an opinion upon the proposal, supported by the Governor of Ceylon, that the Government of the colony should offer a reward for the discovery of a remedy for the coffee leaf-disease.

In the first place it must be remarked that the very language in which the proposal is embodied involves a fallacious conception of the point at issue. It is only by a loose analogy that the enemy which the coffee plant is suffering from in Ceylon can be called a disease at all. There is no evidence whatever that the coffee plant itself is constitutionally enfeebled or unhealthy. But it is now open to the attacks of the hemileia, a fungus or parasitic plant which more or less eats it up. What is meant therefore by "a remedy against coffee leaf disease" is really some method of either destroying the fungus or obviating its attacks. And the discovery of such a method has been the object aimed at in all action taken in the matter since the ravages of the *hemileia* began to inflict serious loss on the coffee planters.

The first thing to do was to find out everything possible about the hemileia and the mode of life which it pursued. The researches of Messrs. Berkeley, Broome, Thwaites, Abbay and Morris established some important facts. The whole subject has been in addition exhaustively studied by Mr. Marshall Ward, a skilful investigator, who has spent two years in Ceylon for the purpose at the Government expense. We now know all that it is practically important to know about the *hemileia* and the question is what helpful indications do we draw from the knowledge?

There appear to be three directions in which it is possible relief may be obtained:—

1. The spores (seeds) of the fungus are blown about by the wind. This being the case the recommendations of Mr. Marshall Ward in respect to this point are of the greatest importance. They are to be found in paragraph 7 page 29 of his third report. "Diseased leaves should be collected and destroyed and every means possible employed to prevent the ingress of winds, cultivation should be directed to these ends, and the pruning and manuring, as far as possible arranged, so that large masses of young foliage are as seldom as possible

exposed, to the spores at those times when they are most blown about."

2. Supposing, however, that the spores cannot be prevented from reaching the trees, it is still possible to kill the former as well as the filaments which issue from them on germination in the very brief interval before those filaments plunge into the leaves and become inaccessible to treatment. This is the principle of the sulphur-lime remedy studied by Mr. Morris. The difficulty, however, is that though the sulphur-lime treatment does its work very effectually; the benefit is only transitory as the trees are apt to speedily become reinforced. Mr. Ward is nevertheless of opinion that the application of a mixture of sulphur and lime, or of lime alone, may be useful in cases where the disease is threatening to denude the trees of leaves at the critical period "when the crop is ripening."

The action of sulphur and lime as far as they go are perfectly satisfactory. Nothing, therefore, appears likely to be gained by experimenting on the action of other substances such as mixtures containing Carbolic Acid. The principle of treatment is in every case identical. One substance may relatively be more or less active than another but none can remedy the difficulty that having killed one crop of the fungus the plantation is still open to fresh infection.

3. The plantations should be closely watched in order to see if individual plants show less tendency than others to succumb to the ravages of the *hemileia*. By sedulously sowing the seed and selecting from the progeny of these, a race comparatively resistant to the attacks of the hemileia might eventually be established.

I think that this statement will enable the Secretary of State to judge how little probability there is of the proposed reward being of the smallest real use. None is certainly required to enforce the common-sense suggestion to protect the coffee plants from spore-laden winds. On the other hand its existence by exciting vague expectations would paralyze the planters in using to the best advantage the practical suggestions already put before them. When the spores have reached the coffee plants, we already possess a means of killing them. That method of treatment has, it is true, disappointed expectations for reasons already explained. As far however as it goes it is not likely to be improved upon. When the fungus has once plunged into the leaves nothing can arrest their destruction short of killing the coffee plant itself.

Supposing, notwithstanding, that the Secretary of State were disposed to approve the reward as a matter of policy, and the more so as there is a minimum of probability of its ever being earned, the administrative difficulties which would immediately arise is connection with it are of the gravest kind. The action of the French Government is a case in point. A large reward has been offered for some years for a means of destroying the Phylloxera which is ravaging the vines of Western Europe. The result has been that while in 1879 alone 334 persons claimed it, a member of the Commission to whom the claims were referred summed up the result as follows:—

"La perspective offerte par ce prix semble d'avoir eu jusqu' ici d' autre résultat que d' égarer des imaginations impressionables, de mettre en mouvement des appétits vulgaires, et non de susciter des travaux sérieux entrepris par des savants ou des agriculteurs exercés et compétents. Le concours ouvert a été un embarras et n'a exercé aucune influence utile."*

Similar evils would undoubtedly ensue in Ceylon. And there is the further difficulty that the thankless labor of sifting the more or less impossible schemes which would be sent in would not, as in Paris, fall upon a body of men removed by the status of European reputation from any possible impeachment of adverse criticism, but would have to be borne by two or three Colonial Officials already sufficiently occupied and whose lives would be made a burden to them by the proverbial contentiousness and wrong-headedness of persons believing themselves the possessors of an inventive faculty. Sir Joseph Hooker is therefore unhesitatingly of opinion that the proposed reward is unlikely to lead to results of any public utility, while it will certainly cause a great deal of embarrassing and unnecessary labor.

As to the proposal that the Government should give aid to persons wishing to make experiments, it is open to such obvious objections that it is really unnecessary to state them. If the planting community agree amongst themselves that any experiments of a particular kind are desirable, the proper course would be that they should carry them out by mutual arrangement and co-operation.

I am &c.,

(Signed) W J. THISELTON DYER,

John Bramston Esq.,
Colonial Office.

* The prospect offered by this prize seems to have hitherto had no result but that of misleading impressionable imaginations, of exciting vulgar greed, and not of arousing serious labors, undertaken by scientific men or practical and competent agriculturists. The open competition has been an embarrassment, and has not exercised any useful influence.—ED.

TEA IN INDIA AND CHINA: THE QUESTION OF NATURAL HYBRIDIZING.

Assam was between the years 1815 and 1824 occupied by the Burmese, who committed the foulest atrocities to the almost depopulation of the country —indeed, the surviving natives stated that the Burmese, when finally driven out by the British, carried away with them the youth of the country, so that only the aged and feeble were left. To this cause the Assamese themselves attribute the sparseness of the population and the feeble character of the individuals. Inveterate addiction to opium eating, induced no doubt by the prevalence of jungle fever, must, however, be at the root of much of the apathy of the Assamese. They are, in truth, almost as much savages as the predatory tribes around them: the Abors, the Garos, the Nagas and other tribes, who must either prove amenable to the influences of Christian civilization, or be improved off the face of the earth which they do little more than cumber. The British might have long had the problem to solve, as to what was to be done with the densely forested, damp, rich-soiled valley of the Brahmaputra, but that about half a century ago attention began to be directed to an indigenous tea plant, which Dr. Wallich, from the large size of the leaves and blossoms, took for a new *camellia*. Of course, our readers are aware that the tea plant really is a *camellia*, but the *camellias* so famous for their flowers are not those that yield the leaves which, when infused, result in "the cup that cheers but not inebriates." Curiously enough, the first result of the discovery that a species of tea grew in the jungles of Assam was not to induce efforts to cultivate that particular plant, but to lead Government to send Mr. Fortune on a mission to China, to collect and bring seeds of what were believed to be the better species of teas, which it was hoped and believed could be cultivated where a tea grew naturally. Some writers on Indian tea, Col. Money amongst them, we believe, regard the introduction of the inferior China teas as a misfortune, but all experience and the general voice is in favour of the view taken by Mr. Baildon in his recently published work on "The Tea Industry in India," that it was well the plants were thus brought into contact, the result being a hybrid far superior to either parent. But, while this hybrid was being developed, the cultivation of the Chinese kinds extended from Assam to the Kangra Valley, Kumaon and the Dehra

Dun in the Northern Himalayas, and Darjiling in the Eastern. In those places China tea flourished and still flourishes, after a fashion superior to anything known in China itself. But it is the vigorous, large-leaved, luxuriant and yet hardy hybrid tea which has converted Assam from a useless tract of jungle into one of the most promising provinces of the Indian Empire. There is much to be done, for Assam with five millions of population has only 9,145 square miles cleared and cultivated. But of this area, 240 square miles (in acres 153,657) are in tea, spread over 1,055 plantations, or "gardens" as they call them in India. That fact accounts for the progress, the trade and the prospect of future prosperity connected with what was once a country of large population, possessed of wealth and a knowledge of the arts, as numerous monuments prove, but which had relapsed into jungle and miasma. The country is being cleared and planted and peopled by immigrants from other parts of India, led by European captains of industry. The recent labour law is a concession to the importance and value of the tea enterprize, and ere long the whilom remote jungle will be joined to the rest of India, not only by river navigation but by means of the iron highway. The railway has, indeed, already made great advances. The enterprize which has, we may say, *re-created* Assam may be taken to have commenced about the time that our coffee industry really attracted the attention of European capitalists, about 1838. In the period between then and now, the planters of Assam have covered over 153,000 acres with tea, while the coffee-planters of Ceylon opened up fully 100,000 acres in excess of that area. As a humid climate is specially suitable for tea, it is matter for regret that we, in Ceylon, did not earlier recognize the fact that a large portion of our island is specially qualified, by climate eminently and in many places equally by soil to be a great producer of tea. We have now made the discovery, and we must follow it out, tea in some cases superseding coffee on cultivated land. We have the accumulated experience of our Indian neighbours to go upon, and the benefit of the hardy and yet luxuriant "hybrid" which their operations originated. The history of this hybrid, if hybrid it really be, throws curious light on the question of cinchona hybrids. Mr. Baildon's theory is that the tea plant is really indigenous to India, and that from India it was introduced to China and Japan about 1,200 years ago. The theory is supported by a legend common to China and Japan, crediting an Indian sage named Dharma with the introduction of a plant which has proved so valuable to the millions of Mongolians. There is a story about Dharma desiring to live without sleep, and finding tea just the beverage for his purpose, which has its counterpart in the story of the coffee bush; while the alleged origin of tea in the scattered eyelashes of the sage resembles the legend of the origin of maize, which Longfellow has embodied in *Hiawatha*. The legendary lore seems to support Mr. Baildon's theory that there is only one species of tea, the Indian, and that the inferior growth and smaller leaves of the China tea are the result of the plant travelling far from home into an uncongenial climate and unfavourable conditions of soil and treatment. Mr. Fortune, therefore, merely took the far-travelled, long absent and terribly changed plant back to its parental home, where again it united with its parents and its kindred. If this theory can be sustained, then, of course there is no question of hybridity, only of two varieties which in the course of ages and by the influence of circumstances had become quite distinct, coalescing and originating a third variety superior to either. Of the superiority there can be no question. The indigenous Assam plant is, in its damp and shady native jungles, a grand plant, and the three or four estates in Assam where this kind alone is grown must be a splendid sight, judging from the patches of pure indigenous we have seen in Ceylon. Really good "hybrid" plants, however, are more certain to grow when planted out, and many of them quite equal the indigenous in size and luxuriance. Removed from its natural conditions of jungle shade and moisture, the pure indigenous Assam tea plant is delicate, feels the sun and exposure, and is altogether behind the hybrid in hardiness. The China is hardy enough, and it has yielded good results in Darjiling and elsewhere, but it is rapidly being superseded everywhere by the hybrid. This so-called hybrid is easily propagated by seed, "after his kind," although occasionally strange varieties appear. Now we have no similar history of the cinchona plant wandering away from its home and being absent for over twelve centuries; but the area over which the plants are scattered on the Andean ranges is widespread enough to admit of room for changes many and great, due to conditions of soil and climate. Originally the feebler *C. officinalis* may have been one with the more robust *C. succirubra*, and what we call a hybrid may be but the reunion of varieties. The analogy of seed coming true to type, however, fails largely: at least so it seems. In the case of *Thea hybridâ* we have a *Thea robusta*, the larger proportion, often the whole, of the seeds of which come true to type. This is the kind of tea which is fully and firmly established in Ceylon, and on which we believe the future prosperity of the colony, shaken by the failure of Arabian coffee, so largely depends. Mr. Baildon's argument for the Indian origin of the tea plant we have marked for extract, and we have indicated his theory of the nature and his estimate of the merits of the hybrid. We quote the concluding paragraph of Mr. Baildon's first chapter:—

Thea Bohea Assamica went away from home, and all lowed botanists (who had not found his parents) to give him the name of *Chinensis*; but he has gone back now to the old country, and has agreed to remain, upon the acceptance of the equitable proposition (resulting from these radical times), that as he and his near relatives are getting old it is useless to quarrel about the family name; so they have made a new one, of a modern cast, for their progeny, which writers on the subject designate in English instead of afflicting it with its doubtful Latin title, and call the hybrid. There is peace in the family at last, and the rising generation is looked upon hopefully.

It is rather a naive idea of Baildon's that 'hybrid' is English and not Latin. It simply happens to be adopted Greek.

It just strikes us as singular, that if an Indian sage,

acquainted with the virtues of tea, introduced the plant to China, his own countrymen should not have adopted the use of the beverage. This is a real difficulty in the way of the theory, but it is not conclusive against it, for many nations have failed to recognize the merits of indigenous products, which when exported have been prized and largely used. The probability seems to be that tea existed in its indigenous state along the range which connects Assam with the north of China. Found on the plains the plant is always a cultivated one : never indigenous. We recollect seeing in Cooper's travels a notice of large tea *trees* in the north of China, which the people stated were five hundred years old !

With reference to what is stated about a lessened immigration to Assam, something must be laid to the account of the rapid and large introduction of rolling, drying and other machinery calculated to supersede manual labour. With one-tenth the number of coolies, rolling and firing are now better and more quickly performed ; and what is true of India ought to be and speedily will be true of Ceylon. Jackson's Tea Roller and Davidson's Sirocco Drier are to the tea planter what Walker's almost perfect pulping machinery was to the coffee planter. The difference is that coffee planting was pretty old before it was helped by the best machinery. Tea planting has this aid at its very beginning. If only consumption goes on as experience leads us to hope, the success of the tea enterprize ought to be proportionately great.

TRADE BETWEEN INDIA AND AUSTRALIA : "GHEE" FROM AUSTRALIA TO INDIA.

A writer in the *Asian*, in concluding some papers on the operations of the Indian Revenue and Agricultural Department, remarks:—

Following up the knowledge which has been derived from the recent Melbourne Exhibition of the requirements in, and present capabilities of, Australia, the R. and A. Department has lately, among other measures, been considering the feasibility of raising an import trade in dairy produce from that colony. The fact exists that we send an appreciable quantity of various kinds of produce to Australia ; and our exports thither have during the last three years largely increased, thus:—

	Value of exports.
In 1879-80	R45,76,210
,, 1880-81	R52,98,699
,, 11 months of 1881-82 ...	R75,29,326

But Australia sends us little or nothing, and the object is to secure a return trade from thence. At present that colony does not seem to be able to send us any produce that requires manual labour. Fruit and a few other articles have been tried, but without any very encouraging results. Dairy produce is the only article which apparently has a chance of being successfully placed in the Indian markets. In considering the project the new department has borne in mind the necessity in any endeavour to promote such a trade, of suggesting that the article be imported in such a form as will meet the tastes of the natives. The only form in which natives in India use dairy produce is *ghee*. Therefore the new department has set on foot measures for the promotion of a trade in *ghee*. The necessary particulars were placed before some farmers in Australia, and, having elicited a request for the services of *ghee*-makers, two experienced men in the industry were sent from this country in February last. Information has now been received of their safe arrival in Australia, and experiments in the making of *ghee* in that colony according to the Indian fashion have already commenced. It is much to be desired that this important and interesting measure will prove successful. No details seem to have been forgotten which can ensure success. Explanation has been sent of the exact way in which the article is packed and presented in the Indian markets, enquiries have been made of the rate of freight and the margin of profit that would ensue, and reports have been obtained from the different Provincial Governments as to the prices ruling in the various markets in India, and the probable quantity of *ghee* consumed in the country. The result of the enquiries under this last head shows that a quantity something like 14 to 15 millions of maunds of *ghee* is annually used in India. This may be said to represent a value of 35 crores of rupees. No detailed analysis is required to establish the importance, in an economic sense, of the measure which the R. and A. Department has taken. In a country like India where pasturage and fodder reserves have so greatly diminished as we have already mentioned, any action which will help the population at large to feed their cattle properly and to reduce the price of dairy produce so largely consumed as milk and ghee, and so necessary in a hygienic point of view owing to their oleagenous properties, must incontestably prove a real blessing conferred on the people.—L.

Ghee, as our readers are aware, is cow butter prepared after a peculiar manner, clarified so as to be readily available for curries, &c.

ASSAM TEA CULTIVATION.

The Assam administration report for the year 1880-81 cannot be said to possess much general interest : nevertheless there are points therein worthy of notice. Assam may be a small province, but it produces a very big report. It evidently must be getting on ; for, whereas in the days when a simple commissioner was sufficient to govern it, its annual history could be told in the few manuscript pages of foolscap to which a revenue commissioner's report extends, that history now requires a volume of 270 pages large octavo, with 138 pages of appendices, printed (and very well printed) at the Assam secretariat press, with a French grey binding and the royal arms stamped thereon all complete. The province, however, only comprises nine districts with a revenue of less than 82 lakhs of rupees, a cultivated area of 9,145 square miles, and a population of under five millions. The Chief Commissioner is also the proud master of no less than twenty feudatory states. These, however, are not of great importance ; for instance the state of Maodon has a population of 305 persons and a revenue of R8-8.

The great feature of the province, that upon which it mainly depends for its coming greatness, is its tea industry. The area planted with tea amounted in the year under report to 153 657 acres, and, notwithstanding a great depression in the industry during that year, none of the gardens were closed, nor was the outturn of tea diminished. The export of tea to Bengal in 1880-81 was no less than 37,715,600 pounds, the total number of gardens being 1,055. The depression referred to, however, markedly checked the appropriation of waste land for tea cultivation ; for, whereas in 1878, 69,000 acres of new land were taken up, and in 1879, 43,000 acres, in 1880 the area of new grants was only 10,000 acres. The importation of labourers for tea cultivation naturally fell in a similar proportion. In 1879 it was 44 per cent less than 1878, and in 1880, 36 per cent less than in 1879, amounting in the latter year to only 16,000 souls. Such a depression of the tea industry, if permanent, would

be a terrible calamity for the province. The only chance for Assam is in the gradual introduction of an entirely new population, for from the Assamese nothing in the way of progress is ever to be hoped. "The total want of enterprize and energy which characterizes all the Assamese is a bar to anything like rapid progress in their material condition. The Assamese cultivator has all the materials before him for accumulating wealth and storing up against evil days, but he has no desire for more than sufficient to eat, sufficient opium, sufficient to clothe himself with and sufficient to shelter himself from the heat or inclemency of the weather. Should a famine ever strike the land he will not, I fear, be found more ready to meet it than the poorest and most rack-rented peasant of Behar."

The above extract is taken from the report of the Commissioner of the Assam Valley, and it mildly describes a state of things which is really phenomenal. The Bengali is not generally regarded all over India as the incarnation of virile energy and overbearing physical power: such, however, is the light in which that abject being appears to the still more abject peasant of Assam. The Assamese speaks of a Bengali as a Bengali might speak of a Sikh or Afghan, and the Bengali when he ascends the Brahmapootra puts on all the airs assumed by a Pathan who comes down to Bengal. Two explanations have been offered for this effete condition to which the once comparatively alert and industrious population of Assam have fallen. One of these is the Burmese mission of 1815. Between that year and 1824 the Burmese ruled the country despotically, and were only driven out by us in the latter year, after perpetrating the most unheard of atrocities and nearly depopulating the country. When they withdrew they carried with them, so the Assamese say, the whole of the youth of the province, and one explanation of the effeteness of the present population is its descent from aged parents. This may or may not be the case, but the depopulation of the country had the effect, in a climate where luxuriance of nature requires constant repression by the labour of man, of permitting the entire valley to be overrun by the jungle in which it is now submerged. The result of this was seriously to impair the health, stamina, and spirits of the population, already broken by the terrible calamities inflicted on them by the Burmese. Add to this the ease with which opium was grown—it is almost a necessity in that climate* —and then it is easy to understand the present moral condition of the Assamese. He has ceased to struggle against Nature. He is the victim of the climate, of the jungle, and the wild beasts, and he resigns himself to his fate. With such a productive soil a very small patch of cultivation would yield the rice and chillies which are all that he requires for food, and the opium which is necessary for his health and pleasure. Why then attempt to cultivate more and thus enter on a struggle with the jungle growth which in a night springs up to smother his sprouting plants; or the deer and hogs, and buffaloes and elephants, which swarm to consume them when in ear? The British now make him pay revenue, and will not let him cultivate the poppy, but sell him his beloved opium at a round price, so he has in these days to exert himself a little more to find the money for both. However, it is no great sum that is required after all, and in other respects he is independent. He requires no clothes; only a little coconut oil to rub on his body, and the coconut is plentiful. His house is made of the grass and bamboos which grow all around him, and he puts it up on bamboo poles to get out of the way of the tigers and other beasts which prowl round the hamlet. Evidently with a population having such few wants, so little ambition, and so little energy, it must always be the case, as the Commissioner of the Assam Valley reports, that "common labour continues to be much what it always has been in this division, expensive and difficult to procure, and, when procured, inefficient whenever the labourer is an Assamese."

Any progress, then, which Assam may make, must come from without. The population is not prolific; it is very doubtful, indeed, whether the birth-rate much exceeds the death-rate. Of themselves it is most improbable that the Assamese would ever again increase to the teeming population the traces of which are to be found everywhere—in tanks and embanked roads, and forts and village sites—hidden under the universal pall of grass jungle spread like a curse over the land. Certainly it was not a country to tempt immigration through its own attraction, so its prospects were really very hopeless until, not a quarter of a century ago,* a Mr. Bruce discovered the indigenous tea plant. Since then the tea industry has galvanized the province into life. Between the census of 1872 and that of 1881 there has been an increase of population of nearly 19 per cent. This, says the report, is in those districts which are "the chief tea-producing tracts, and the large increment to their population is mainly the result of the extension of this industry." But tea, besides adding year by year largely to the population (as much as 50,000 to 60,000 souls per annum), and clearing the jungle and draining the soil (thus improving the climate), has created a trade of nearly 5½ crores, more than half of which is the tea itself, and the rest the result of the money which the industry has poured into the country. Tea has also created communications. Twenty years ago Assam was completely cut off from the outer world. From the Eastern Bengal Railway terminus at Kooshtea, a steamer struggled up the Brahmapootra once a month, taking a month to perform the trip to Dibrugurh. Now the railway reaches to Goalundo, whence a *daily* steamer service has been organized, and lateral communications with the river by means of tramways are in course of construction.

Tea being thus to Assam what coal and iron are to Wales or cotton to Manchester, it would be natural to suppose that every effort would be made to foster that industry. Hitherto the case has been rather the reverse, but the administration now appears to have taken up the tea interest and the disabilities imposed thereon in the matter of import of coolies are being removed. Act I of 1882 is a tardy act of justice to the body of enterprizing Englishmen who have made Assam.

It may well be understood how worthless the indigenous Assam population is when we quote the Chief Commissioner's remark that over 1,550 maunds of opium were consumed in 1880 in the five upper districts of the Assam Valley, the revenue from the drug being 17 lakhs of rupees. The Assamese will do a few days' labour in a tea garden to obtain the money necessary for this opium and for the Government revenue (which is extremely lightly assessed), and will then work no more than is necessary for his little crop of vegetables and rice. "Want of cheap labour," writes the Chief Commissioner, "is the great difficulty of administration in Assam." That difficulty has to be got over by importing a new population. Such a measure which, for Government is impossible, as was seen in the failure of all attempts at aided emigration, is being carried out gradually by the operation of the tea industry.—*Pioneer.*

* Until its use is superseded by a plentiful supply of the cinchona alkaloids.—ED.

* It is more than *half a century* since Mr. Bruce succeeded in drawing attention to the Assam tea plant, which had been noticed and reported on years previously by a Bengal civilian named Scott.—ED.

INDIA THE HOME OF THE TEA-PLANT.

Doubts have been expressed in the last few years as to the accuracy of the general belief that the tea-plant had its home in China.

It must be admitted to be rather late in the day now to advance theories as to the nativity of a plant whose cultivation has been carried on for centuries. At the same time there will be nothing lost by looking into such records as exist, to see what information can be obtained on the subject.

Theorists are always eminently convincing to themselves; so in the present case, I know one individual who feels quite sure—no matter how general or ancient be the belief to the contrary—that India is the natural home of the tea-plant.

Ball, in his exhaustive and valuable work, *the cultivation and manufacture of tea*, says (p. 15), "It may be here proper to remark that on the authorities of certain Japanese authors, a doubt has been raised by the Dr. Von Siebold, an intelligent botanist some years resident in Japan, as to the tea-plant being indigenous in China. All are agreed that it is of exotic growth in Japan, and was introduced into that country from China in the sixth century, agreeably to Kæmpfer, or the ninth century, (which seems more probable) according to Von Siebold."

The early history of the tea-plant is surrounded by the cloudy legends and mythological narratives of the imaginative Chinese. One writer says:—"The origin of the use of tea, as collected from the works of the Chinese, is traced to the fabulous period of their history. The earliest authentic account of tea, if aoything so obscure and vague can be considered authentic, is contained in the *She King*, one of the classical works of high antiquity and veneration amongst the Chinese, and compiled by their renowned philosopher and moralist, Confucius. In this treatise, (*Kuen Fang Pu*), in the article "The Ancient History of Tea," an absurd story is related of the discovery of this tree in the Tsin dynasty. In the reign of Tuen Ty, in the dynasty of Tsin, an old woman was accustomed to proceed every morning at daybreak to the market-place, carrying a small cup of tea in the palm of her hand. The people bought it eagerly; and yet from the break of day to the close of evening, the cup was never exhausted. The money received, she distributed to the orphan and the needy beggar frequenting the highways. The people seized and confined her in prison. At night she flew through the prison window with her little vase in her hand."

Another (legendary) version of the origin of the tea-plant, is, that in or about the year of grace 510, an Indian prince and religious devotee named Dharma, third son of King Kosjusva, imposed upon himself, in his wanderings, the rather inconvenient penance of doing without sleep. The little Chinese narrative says that the Indian gentleman (who must have differed vastly from his countrymen of the present day), got on very comfortably for some years; until all at once he gave up, and had forty winks on a mountain-side. Upon awakening, Dharma was so grieved to find that he could not move about for years without going to sleep, that he pulled out his eye-lashes and flung them on the ground Coming round that way later on, he found the offending lashes had grown into bushes, such as he had never before seen; and his long ignorance of sleep not having taken all the curiosity out of him, he nibbled the leaves, and found them possessed of an eye-opening tendency. He related the discovery to his friends and neighbours, and the tea-plant was forthwith taken in hand.

This, the most generally accepted indication of the first notice of tea in China—vague and legendary, I admit, but nothing more accurate is obtainable—uses the name of Dharma as the promoter or creator of the tea-plant. The actual records speak positively of such a man, saying he was a native of India, probably a Fakir, and that he crossed to Japan. Kaempfer states, upon the authority of Japanese chronicles, that tea was introduced into that country by a prince of the name of Dharma.

It will be advancing no theory to say that many mythological legends are based upon actual occurrences. In this year of enlightenment, 1881, we do not, of course, believe that a man named Dharma—especially an Indian—lived for years without sleeping, any more than we do that the tea-plant came out of his head: but it is possible, and even very probable, that the plant was brought to the notice of the Chinese by Dharma, just as it was to that of the Japanese by the same person. And when the ancient history of China is studied, one is quite prepared to find that a matter of past discovery or introduction has been enshrouded in a fanciful record verging upon, if not actually clothed in, the allegorical, while at the same time indicating the actual. Yet, do what we will, we are, of course, guided by conjecture; by reason of which, at this late date, it is difficult either to prove or deny the existence of the tea-plant in China anterior to, or through the agency of Dharma.

Briefly, the matter stands thus. The most feasible of the Chinese *legends* on the subject makes the existence of the tea-plant in China to have originated with Dharma, who came from India in A.D 510. The Chinese *chronicles* tell of such a visitor during the reign of Vû Ty, A.D. 543, stating that he came from India and crossed to Japan. The Japanese chronicles record the visit, and say Dharma introduced the tea-plant to that country. The Chinese and Japanese versions of the first phases of tea in their respective countries are thus attributed to a native of India. If we enter into the conjectural domain of "perhaps," there will scarcely be a limit to surpassing whatever we may advance. I will therefore venture only one "perhaps," and I feel quite sorry to do even that, having no doubt that Dharma was a very respectable individual, when doing the tea-plant business in China, at the time that England was divided into several kingdoms.

My one "perhaps" is this; and I think all who understand the Indian character at the present time will admit that it is not a far-fetched one. Perhaps Dharma, finding he was introducing to the Chinese an unknown plant, possessing peculiar properties, accounted for its existence in true Oriental fashion in a way not lowering to his own importance in the eyes of a superstitious people.

Mr. Ball says (p. 17):—"Recent discoveries in Assam also seem to justify the assumption, if nothing to the contrary be known, that it (tea) has spontaneously extended its growth along a continuous and almost uninterrupted mountainous range, but of moderate altitude, nearly from the great river the Yang-tse-Kiang, to the countries flanking the south-western frontier of China, where this range falls in with, or agreeably with the opinion of a well-informed and scientific author, Dr. Royle, forms a continuation of the Hymalayan range. But in those countries, as in every part of China, if found in the plains or in the vicinity of habitations and cultivated grounds, it may be fairly assumed that it was brought and propagated there by the agency and industry of man.

There is neither a record, nor anything approaching a reasonable legend, to prove that tea was discovered in a wild state in China before Dharma brought it to notice. The earliest mention tells of people using it, and it may be inferred therefrom that they cultivated it. Precise and accurate information is obtainable as to the actual discovery of tea in Assam, *away* from habitations, and in dense jungles, far from "cultivated grounds." But similar

information is not obtainable in connexion with the first days of tea amongst the Chinese. We may reasonably suppose that the place in which nature plants anything is better suited to its growth than a chance one of man's selection, and also that nature does not plant a shrub in a place of medium suitability, and leave it "spontaneously to extend its growth" into a more fitting spot many hundreds of miles distant. And as to the suitability of India for tea, there can be no question; for even what is known as the Chinese plant gives a better return in India than in its reputed native land. We may either dispense with the agency of Dharma altogether, as having introduced the plant to China from India, or just reverse Mr. Ball's theory, and suppose that instead of the plant being indigenous to China and extending its growth along the countries mentioned into India, that it was indigenous to India, and extended its growth to China, *deteriorating as it did so.*—*S. Baildon's "Tea Industry of India."*

WATTLE CULTURE.

IT is quite true that in some cases "What is one man's meat is another's poison," and we have an agricultural case in point in the matter of wattle. We re-print an article from an Australian paper, *The Ovens and Murray Advertiser*, under the above heading. From a perusal of this, it will be seen how differently the wattle is thought of in Australia to what it is in India. Here we look upon it as a poison to the ground, as it certainly is. Grass will not grow side by side with wattle; the latter soon exterminates the former, and search is made in vain for fodder for cattle in between the growth of wattle. It is obnoxious and of no use. In Australia, on the contrary, the bark is made useful and, as we read below, wattle "will not interfere to any appreciable extent with grazing."

The above is from the *South of India Observer*, and the extract which follows shows that the wattle can be cultivated in Australia on the most arid soil. The reason why the plant becomes a nuisance in India and Ceylon is because our moist climate encourages a too dense and luxuriant growth from the roots. Trials should be made on patana soil. The bark would be useful for tanning and the timber for fuel on tea estates, &c.

BISHOP MOORHOUSE (OF MELBOURNE) ON IRRIGATION.

KERANG, 18th March.—Bishop Moorhouse delivered a lecture on irrigation tonight at the Mechanics' Institute. There was a very large attendance. The Bishop said that about three years ago he ventured upon a prophecy. He predicted that, if the then existing state of things as regarded water supply continued much longer, there would be a water famine. He found his prediction verified, when he crossed the plains a few days ago, and saw nothing but despair on every hand—no water, no verdure, and everything parched and withered, and suffering on every hand by both man and beast. We possessed a fertile land, the finest of all the Australian colonies, perhaps, excepting New Zealand and Tasmania. He loved Victoria and wanted to see her wealth increase, but the people and their legislators must exhibit courage, promptitude and energy in dealing with national questions. Wealth depended on productiveness, not on the mere spending of money. The man that spent his money in gratifying vicious habits did not produce. His expenditure of money was only waste, and unproductive. Ten thousand a year spent in this way did not add to the wealth of the colony. Who were producers, and what was produce? The gold obtained from the mines was produced, but it cost £4 15s to gain £5. Therefore that labour was not very productive. Beef and mutton were our most profitable productions. A protective policy was said to be necessary for fostering local manufactures and providing employment for the young people. But it appeared that the articles so produced could not be sold at remunerative prices. It appeared that only in this colony they could be disposed of with a profit. The farmer and squatter were the only real producers. They were the most valuable portion of the population, the backbone of the colony, and the basis of its permanent prosperity. How were they to succeed? Only by permanent cultivation of the soil. This meant irrigation and putting something into the ground for what was taken out. Irrigation and manuring were the basis of permanent cultivation. Public opinion could not alter the laws of nature. He had looked over the beautiful and fertile plains of Lombardy, in Europe, and there seen a land twenty miles square, which supported an immense population under a grand system of irrigation and cultivation. The farmer must grow plenty of corn, hay, lucerne and root crops for his house cattle, in order to raise manure, and he must divide his land into ten-acre blocks to successfully irrigate it. He had been told that it was impossible to irrigate the lands of South Australia and New South Wales. If that was so, then he said there could not be any permanent cultivation in those colonies. An experienced engineer had assured him that portions of Victoria could be successfully irrigated for five miles on each side of the Goulburn river. He had entered into a calculation, and found that, if a good scheme of irrigation was started there, a population of 65,000 people could be maintained on the banks of the Goulburn alone. It was imperative upon the Government to undertake these costly national works. Let the farmers go to their parliamentary representatives and say: "You must give us water." They should not give a vote to any man who would not work energetically to obtain this boon, no matter what his political creed may be. At the same time water-boring should be also carried on, and every selector ought to deepen his dams and tanks, and endeavour to help himself. Those who lived on the banks of rivers had a fine opportunity of raising water by windmills. He was informed that a farm on the Campaspe, originally let at £4 an acre, had an engine and pump erected on it for irrigation purposes, and was now let at £40 an acre. The Government was building railways, expecting to have men and produce to carry; but, if they did not also provide a good comprehensive water supply they were only wasting public money in building these railways. He advised the selectors not to give the people of Melbourne any rest until a comprehensive water supply, scheme for the country districts was taken up, and when this work was accomplished there would be no finer country in the world than Victoria.—Melbourne *Age*.

INDIA-RUBBER.

Under this head a great deal of space is devoted in the latest Kew Gardens' Report, to the several plants which yield the different rubbers of commerce. On the subject of the Central American rubber plant, *Castilloa*, in Ceylon, Dr. Trimen is quoted as follows:—"Two plants have been sent to Calcutta. Those in Burmah are reported to be flourishing. Much better success now attends the propagation, by cuttings, of this fine species. Our largest trees at Henerat-goda have now a circumference of nearly 17 inches or a yard from the ground, and the trees are beginning to take their true form."

Ceara Rubber (*Manihot Glaziovii*), Ceylon.—Dr.

Trimen says this is still the only species which has flowered. "Seed has been supplied, during the year, to the Government gardens in India (Calcutta, Saharunpore, Ootacamund), and distributed as widely as possible among the planters in the colony, 24,550 seeds having been thus disposed of, as well as 1,879 rooted cuttings. We have also sent small quantities to the Botanic Gardens of Singapore, Mauritius, Jamaica, British Guiana, and Kew, the Acclimatisation Society of Queensland, and Mr. Lowe, Her Brittanic Majesty's Resident in Perak."

Dr. Trimen adds:—"This plant is now flourishing in Ceylon in suitable places, and proves very hardy; in the new estates in the Trincomalee district it is reported to be thriving, but to have shown itself intolerant of wet. In the Nilgiris, I am informed, it is doing well at 2,400 feet; and Major Seaton reports from British Burma that there are 500 and upwards set out, and well established in the Mergui plantation."

Jamaica.—Mr. Morris reports:—"This plant is evidently of a very hardy character, and adapts itself readily to the exigencies of culture. Plants at Castleton (600 feet) and at the Parade Garden, Kingston (50 feet), are doing well. At the former gardens, young trees, when about 9 to 12 feet high, were beginning to flower, but the hurricane deprived us of the hope of procuring seed this year. Judging by reports from South America, it is possible that tracts of dry, stony—almost worthless—lands, in the plains, may be turned to good account by means of this cultivation."

Para Rubber (Hevea brasiliensis).—On the cultivation of this rubber plant in Ceylon, Dr. Trimen reports that "it will be probably found to be satisfactory only in rich land, not much above sea-level, where the temperature is high and equable, and the rainfall large. At Peradeniya, the trees are making but slight progress, and suffer from wind, especially in the dry north-east monsoon. At Heneratgoda, their progress is all that could be wished. Our largest trees are now, at three feet from the ground, 16 inches in circumference. During the year, 662 cuttings were raised and distributed. *Hevea* has proved completely unsuited to the climate of Calcutta, but is doing well in Burma and Perak. In the latter place, a tree has flowered sparingly, at 2½ years old, and 35 feet high."

African Rubbers (Landolphia spp.).—On this point it is stated that all the present commercial sources of African caoutchouc belong to the above genus, which is a group of woody climbers, all of which probably yield caoutchouc peculiar to tropical Africa and the adjacent islands. African caoutchouc comes into commerce, both from the west and the east coasts, and only one of the rubber vines is common to both. Three species of *Landolphia* are described as producing caoutchouc on the West Coast of Africa. The form in which West African rubber comes into commerce is somewhat peculiar: it is accounted for by the method of collection, which has been described as follows:—Every part exudes a milky juice when cut or wounded, but this will not run into a vessel placed to catch it, as it dries so quickly, and forms a ridge on the wound, and stops its flow. The blacks collect it by making long cuts in the bark with a knife, and as the milky juice gushes out, it is wiped off continually by the fingers, and smeared on their arms, shoulders and breasts, till a thick covering is formed. This is peeled off their bodies and cut into small squares, which are then said to be boiled in water. The three species referred to above are *Landolipha owariensis*, *L. Monnii*, and *L. florida*. From the East Coast of Africa four species are referred to as furnishing rubber of commerce, namely, *L. florida* (before referred to on the west), *L. Kirkii*, *L. Petersiana*, new and undescribed species, and a species though distinct, not yet sufficiently known to admit of scientific description. The following extract from a report to the Foreign Office by Mr. Holmwood, the Vice-Consul at Zanzibar, is descriptive of the mode of collecting the rubber:—"The process consisted in cutting clean slices of bark from the trunk and branches, from three to ten inches in length, and from ½ to ¾ inch in breadth. The cuttings were made sometimes from one side only, but generally they were rscoed all over the tree, about half of its bark being thus removed. The method of making the balls of rubber—which average two inches in diameter—is as follows:—A quantity of milk is dabbed upon the forearm, and being peeled off, forms a nucleus This is applied to one after another of the fresh cuts, and being turned with a rotary motion the exuding milk is wound off like silk from a cocoon. The affinity of this liquid for the coagulated rubber is so great, that not only is every particle cleanly removed from the cuttings, but also a large quantity of semi-coagulated milk is drawn away from beneath the uncut bark, and during the process a break in the thread rarely occurs. By working hard, one person can collect 5 lb of rubber, per diem, though the average is one half thisamount. I was assured, however, that in the interior, where the trees were large, it is no uncommon thing for one man to collect 7, or even 9 lb. in a day. The regular season for the collection of india-rubber lasts from about the middle of May till the first week in December. This has little connexion, however, with the state of the tree, but is owing to the natives being generally engaged during, and for some time after, the rainy season in cultivating their lands." He further reports, that, in the districts of Mungao and Kilwa alone, india-rubber "has created a new trade, which finds profitable employment for all those classes whose means of subsistence came to an end with the suppression of the illegal slave trade. The total exports from these places now (1880) exceeds 1,000 tons annually. Since last season the price has risen from £140 to £150 per ton, and there seems no reason to suppose it will ever again fall to the former figure." With regard to the destruction of the rubber vines by the collectors, Vice-Consul Holmwood takes a somewhat gloomy view. He says it is "admitted that, while three years ago the supply of india-rubber was altogether derived from the country within 50 miles of the coast, the great bulk was now procured from Mahenge and Ubena, countries distant 150 to 200 miles from Kilwa; the supply from the more adjacent districts, having, moreover, greatly fallen off, and, in some instances, entirely ceased." Consul O'Neill more recently remarks, in his report for 1880, on the trade of Mozambique:—"It is curious to note the marvellously rapid development of the india-rubber industry. In 1873, only £443 worth of india-rubber passed through the Custom-house of Mozambique; in 1876, it reached the value of £22,198, and in 1879, it exceeded £50,000. It would seem, now, to have reached its climax, while the present rude method of collecting this produce prevails, and until communications with the interior are properly opened up, for the careless cutting of the trees by the untaught hands of the natives has resulted in the destruction of enormous tracts of india-rubber forests near the coast."

From specimens of rubber-yielding plants received at Kew from Sir John Kirk, it seems that one of the Zanzibar plants is a species of *Landolphia* hitherto unknown to science, and now proposed to be called *Landolphia Kirkii*, in honour of Sir John Kirk. With regard to the mode of collecting the rubber from *Landolphia Petersiana*, Sir John Kirk thus describes it in a report to the Foreign Office:—"The mode of preparation of this india-rubber differs essentially from either of the other two kinds, the juice being here gathered in a fluid state, by

tapping, and coagulated by heat, or in some other way, similar to that used in Madagascar or the Brazils. The product, however, is said to be of an inferior quality."

On the subject of Borneon caoutchouc, the Kew report says:—"The most authentic information on the caoutchouc-yielding species of North-West Borneo is apparently that contributed by Mr. Treacher to the "Journal of the Straits Branch of the Royal Asiatic Society," for July, 1879 (p. 58). He enumerates no less than eight, with the following names:—

"1. Manungan pulau (*i.e.*, Manungan proper).
"2. Manungan bujok.
"3. Manungan manga (light coloured bark).
"4. Manungan manga (dark coloured bark).

"From the above is obtained the gutta lechak or gutta susu of commerce. (*Gutta* in Malayan means gum; *lechak*, elastic; *susu*, milk).

"5. Serapit larat.
"6. Serapit pulau.

"The produce of these is only used to increase the weight of the manungans, the milk not hardening sufficiently of itself.

"7. Bertabu or Petabo pulau.
"8. Bertabu or petabo laut.

"The produce of these is no longer marketable. The different plants would appear to be accurately distinguished by the native collectors; and, if the best of them are to be sought and brought into cultivation, their precise botanical identification becomes important.

"No. 1 of the foregoing list is referred to as a new species of *Willughbeia*, the name proposed for it being *Willughbeia Burbidgei*.

"No. 2 is *Leuconotis eugenifolius*.

Nos. 3 and 4 are supposed to be species of *Willughbeia* and *W. Treacheri* is proposed for No. 5.

"The remainder would at present seem to be undeterminable. All the above species belong to one natural order, namely, *Apocynaceæ*. Other caoutchouc yielding plants are referred to in the report, which are, however, of minor importance as compared with those just enumerated.

"Regarding the collection in Perak of *Gutta singgarip*, the produce of *Willughbeia Burbidgei*, the following description is given:—'The stem is generally ringed at intervals of 10 to 12 inches, and the milk allowed to run into vessels made of palm or other leaves, coconut shells, or anything available for the purpose; it continues to flow for some time, but after flowing for some minutes, it gets very watery and thin.

One flow will yield from five to ten catties of the coagulated caoutchouc. When raw, it has the appearance of sour milk, and, to coagulate it, the natives add salt, or salt water. When freshly coagulated, it is quite white, which gradually changes to a darker colour. It keeps white inside, and, on cutting, it presents a foveated appearance, the cells containing water and salt, which have become enclosed during coagulation. In texture it is soft, very spongy, and very wet."

COFFEE CONCOCTIONS:

AND HOW TO MAKE THEM.

A recent analysis of coffee affords strong grounds for the conclusion that such a thing as pure coffee exists only in the imagination of "the pure to whom all things are pure." Out of thirty-seven specimens, three proved to be actually devoid of any coffee whatever. Even that "sold as a mixture of coffee and chicory" proved a downright sell, the chicory itself being adulterated. Dates and dandelions are comparatively harmless, but there were besides, potatoes, carrots, parsnips, beans, mangold-wurzel, acorns, biscuit-powder, burnt sugar, and general vegetable matter ("What's the matter?" we should like to know?) As if these were not enough, there have been found also in coffee Venetian red, burnt rags, and rope-yarn, lentils, and ground lupine seeds, sawdust, horses' hearts (to think that adulterators should "have the heart to do this!"), and baked bullock's liver.

We thus see that a great deal of the fine Jamaica coffee is not "real jam" at all, and that the best Mocha is a mere Mocha-ry. As to the victims of such frauds, we might ask them, in music-hall language:

"How do you like our coffee? what do you give a pound?
How do you like baked horse's heart and lentils finely ground?
How do you like Venetian red, rope, sawdust, rags, and such?
How did you get that poison down, and *did it hurt you much?*"

—*Funny Folks*, April 15th.

AGRICULTURE IN AMERICA.

For some years past the attention of the Department of Agriculture in the United States of America has been directed towards supplementing the amount of sugar produced in the country, and that almost entirely from the ordinary sugar-cane (*saccharum officinarum*), by encouraging the extraction of sugar from *sorghum*. America consumes an enormous quantity of sugar, the annual consumption being estimated at 40 lb. per head, or for the whole population two thousand million pounds. As the production in the States hardly exceeds two hundred million pounds, it is evident that nine-tenths of the sugar used must be imported. *Sorghum* is a variety of maize, says the *Field* to which we are indebted for some information on a subject which has not escaped the notice of our local Department of Agriculture. In America they profess to have thirty-two varieties, of which the favourite is the early amber. This only occupies the ground ninety days and also contains the largest proportion of saccharine matter, to the acre, of the quicker-growing varieties. The Honduras *sorghum* which gives the heaviest yield of cane, occupies the ground longer, and the syrup obtained from it is inferior. It is estimated that from 60 to 65 per cent of juice should be given by the stripped cane, and that, if the cane be cut at the proper time *i.e.*, when the seed is thoroughly matured, from 12 to 16 per cent of the juice should be sugar, that is to say 100 lb. of stripped cane should yield 5½ lb. of sugar. The great merit of the *sorghum*, as compared with sugar-cane lies in the short time that it occupies the ground, only ninety days instead of the whole year. The experiments made by the N.-W.-P. Department of Agriculture appears to have failed in obtaining proper granulation of sugar from the syrup. Much of the success in this direction depends on the cane being cut exactly at a favourable period of its growth, and in this the *sorghum* affords a better guide than ordinary sugar-cane: the hardening of the seeds being a sure test of the maturity of the cane. The seed too affords a useful food for cattle, though it would be best given in a crushed form. Moreover the *sorghum* yields its own seed, whereas in the case of cane a large proportion has to be set aside for seed canes for the following year. The manufacture of sugar from *sorghum* requires no expensive machinery. It is difficult to compare the profits obtained under the system of agriculture in America with those obtainable in India, but a low estimate would appear to give in America an outturn of 200 gallons syrup to the acre, worth 100 dollars, the cost of cultivation being only 6¼ dollars per acre. The experiment of growing *sorghum* for sugar is well worth trying by agricultural experts and others desirous of

improving the agriculture of India. There is risk, as in all experiments, of failure at first, but only in the more technical details of converting syrup into sugar. These unquestionably can be overcome, and the many points in which *sorghum* can be more profitably and more easily grown than cane recommend it at least for a thorough and exhaustive trial.—*Pioneer.* [*Sorghum* is most valuable as a specially nutritious food for cattle, but, when the Americans have succeeded in obtaining a profitable return of crystallized sugar from the stalks, it will be time enough to try any of the *sorghums* as substitutes for the true sugar-cane, which yields twice the amount of saccharine matter, weight for weight.—Ed.]

POETT AND MACKINNON'S COFFEE PLANTATION.

A MAGNIFICENT ESTATE—AN EXTRAORDINARY SPRING—CINCHONA PLANTING—CHEAP LABOUR WITH A VENGEANCE—THE OLD CRY, "CONCESSIONS."

Such are the headings to the following report by the special correspondent of the S. A. *Register* on the land in the Northern Territory thus described :—

"There was a thunderstorm with a heavy fall of rain in the afternoon, but we pushed through it to the Rum Jungle, about midway branching off to the west to see Poett, Mackinnon & Co.'s coffee plantation. They have altogether 3,500 acres, and from the time we entered its western boundary till we left its northern we were riding through a grandly fertile plain of red-and-chocolate soil, generally only damp, despite a rainfall, and not boggy. There was but one exception to this rule. That bog resembled an agglomeration of wet blacking, and our horses sunk in it as though it had been a quicksand. In every part the land is covered with long grass; it has thick patches of jungle; and altogether has more of a tropical appearance about it than any other piece of scenery we have passed here yet.

"At the clearing, which has been made at a most picturesque spot, we met Mr. Mackinnon, who has had a good deal of experience as a planter in Ceylon, and who is acting as manager in the absence of Poett. Work was begun on the 11th of last December, and already a patch of about four acres of jungle has been cleared. On it the framework for a capital bungalow has been erected, several huts and offices have been built, and two acres have been trenched and closely fenced for use as a nursery. In this one bed has been planted with cinchona, which was just peeping above ground. The seed was not good. Mr. Mackinnon says that he expects only 4,000 or 5,000 plants instead of twice as many. The beds have all been prepared for the reception of Liberian coffee—they fear the Arabian will not succeed. The seeds will probably arrive by the next Hongkong steamer, for Mr. Poett is in Ceylon sending it out. He is also arranging for a supply of Tamil labourers, who get 8d a day there, and who would, he believes, go to the Northern Territory for 2s a week more ! ! Mr. Mackinnon assured me that he would have no difficulty in getting 500 or 1,000 men at that rate; and he speaks in the highest terms of the Tamils as workmen. At present six Chinese, at £1 a week and the privilege of free cartage of rations, are employed on the plantation, and the manager characterizes them as lazy and impertinent. The Chinese carpenter gets £3 10s a week. The intention is to put 500 acres under coffee next year if possible; and also to plant cocoa, the india-rubber tree, and maize, amongst other things. Three years hence (Mr. Mackinnon thinks) there will be 500 men employed on the plantation.

"After partaking of Mr. Mackinnon's hospitality, and drinking success to his company's venture, we went over the clearing, and saw one of the prettiest sights the Territory has to show. Near the office, in the middle of the creek, is a dense jungle, made up of trees unusually tall and stout, with intertwining laces of wiry creepers making an impassable network between their trunks. At one point a matted roof is formed in this way, leaving a clear space of a dozen feet from the ground. Below there lies a cool and limpid spring like a sheet of glass—so beautifully transparent. Looking some feet to its bed you see a slight displacement of its white sand crust in about a dozen places. Through these the water bubbles brightly up, and the spring is never less or more than it was when we saw it. It is a truly beautiful place, and the estate is a magnificent one. But yet the company, though getting their land under the most liberal of the Northern Territory laws, are asking the Government to give them concessions in respect to fencing and other matters. If these concessions be refused, and, if the land be dropped, I know of men who would take it up at a price half as high again as that the present owners paid."

The correspondent adds on the territory generally :—"Personally I have had exceptional facilities for collecting information; and, that it may be perfectly trustworthy, I have been at some pains to check from different quarters any relation of reported facts respecting which there was any possibility of doubt. I have indeed erred by intent rather on the side of under-tinting than over-colouring; and, in closing this part of the narrative of the trip I can only repeat generally that the country abounds in minerals the extent of which has to be proved by trial, which has never yet been applied, or where slightly used with results perfectly satisfactory; that a comparatively small proportion only is fit for cultivation; and that almost all of it is good for grazing. There are many suggestions which will be made when this record shall have concluded. In the meantime, I may give, as the result of very careful enquiries, the opinion that, in the whole of the mining districts, including storekeepers and Government officers, there are scarcely 250 Europeans. The Chinese I estimate at 2,500. There is great difficulty in arriving at an absolutely exact computation of their numerical strength, because they are scattered over so large an area, but I interviewed the leading Chinese merchants and gold-buyers in every place I came to, and they gave me as approximately accurate the total I have given—a total verified by my own observation. I cannot too strongly impress upon the reader that there has, as a matter of fact, been positively no sustained systematic attempt to develop any part of the mineral country. There are all over the Territory only nine batteries, and all more or less defective. I have seen all of them, and at the time of my visit only three were working, or had been for some time. It is not too much to say that eight-ninths of these crushers lose at least one-third of the gold, and that fact should be remembered in the computation of the yield the stone they treat returns.

"The main drawbacks to the prosperity of the mining industry will have a reference hereafter. At present I will only incidentally refer to the operation of the swindles—that is their name up here—of some years ago. To them primarily is traceable the ill-savour of mining enterprize here ever since. In several cases companies were formed with fluctuating share-lists which did no work at all. Land was pegged out anywhere, leases were applied for, and the venture sold when not a single prospect had been taken. A well-known and 'straight' mining manager in one of the principal centres here assures me that years ago he received no fewer than four telegrams in one day from brokers in Adelaide to this effect :—'Peg out claim anywhere. We'll float it.' What but a crash

could come of this? A crash did come, and I direct attention to the facts now, that a repetition of anything so disgraceful and so utterly inimical to the best interests of our grand northern estate may be avoided. I can see—any enquiring visitor can see—that the dulness and the apathy in the Territory, and the disgust outside respecting the Territory, were all born of this floating and bursting of bubbles in the days gone by. For legitimate enterprizes, and for well-directed speculation, there is no better field than the Northern Territory presents, and granted a railway I warrant that our reviving white elephant will soon develop into one of the most useful animals any colony could wish to be blessed with."

We cannot be surprised at the *Register* reporter's notes of admiration about Mr. Mackinnon's statement that he could get any number of coolies from Ceylon at a little over 8d per diem. Coolies accept wages in Ceylon at which they would not labour in the northern territory of Australia, and Ceylon is not a recruiting ground for Indian coolies.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special letter.)

PARIS, April 22nd.

Maize is largely employed in France for the production of spirits and starch; in both cases the residue has an importance as an article of cattle food at once cheap and nutritive. The flour of all cereals in addition to starch contains gluten, fatty matters, gum, mineral salts, &c. When the maize has been softened in water, it is carried up to a pulp engine and reduced to liquid paste. By successive screenings, the starch is separated, and the residue is a yellowish mass, possessing an agreeable odour, capable of being preserved in trenches, and well relished not only by cattle but by horses, pigs, and barn-door fowls. It contains still 8 per cent of starch, 1½ of gluten, 2¾ of fatty matters, and 7 of sugar. It can economically replace oil cakes, as 6 cwt. of the paste at 15 fr. is as nutritive as 2 cwt. of linseed cake at 23 fr. The secretion of milk is augmented, yielding a quality not only rich but of an agreeable flavour. In the north of France the farmers use the refuse of the starch mills very largely.

There is a warm rivalry going on respecting the nutritive and economical value of palm and cocoa cakes *; nitrogenous matter predominates in the latter, and fatty substances in the former. For pig feeding, both cakes are mixed. In the centre of France cocoa cake is generally employed for milch cows; the milk produced on this regimen is rich and the butter fine and well-flavoured.

In Brittany, Jerusalem artichokes, 23 lb. per day ration, are competing with parsnips in the feeding of horses. They produce a sleekier coat, and the animals relish them better; then they remain more juicy at the end of the season, when parsnips and carrots become dry and insipid. Parsnips demand a deep silicious soil, and, if near the sea, so much the better. The white carrot with the green neck has the drawback of not preserving well, and, last winter being mild, their conservation was very difficult. To meet the difficulty many farmers here cultivate the white carrot for first consumption, and the long red variety for later feeding, up to May, as it keeps well, and is highly relished, perhaps from its perfume.

Professor Sanson maintains that the native breeds of live stock of France have been so improved by judicious crossings with imported pure races, as to be chemically and nutritively, in point of meat, superior to the latter. Be this as it may, stock-breeders and judges at agricultural exhibitions display still a weakness for pure stock. M. Sanson has analyzed portions of the prize animals' flesh at the recent Paris Fat Cattle Show, to determine the percentage of dry matter, of protein, and of fat, deducing therefrom the comestible value of the animal. Following his tests, in the case of stock, the Limousin breed would come first, and Durhams last; for sheep, precocious merinos, a dishley cross, and Southdown lambs. In the case of three breeds of pigs, the Normand and Limousin Yorkshires are superior to the pure Yorkshire. Allowing a good deal for patriotism, it is not clear what rôle difference of age has played in the comparison.

Professor Nocard, of the Veterinary College of Alfort, has remarked that many cases of the *charbon* malady were to be traced to lands dosed with such artificial manures as blood, refuse wool, &c. It is wise to take note of the observation without attaching to it undue importance. The Pasteur vaccination preventive against the *charbon* disease is now unanimously accepted in France. Many local agricultural societies undertake to repay the expenses of vaccination to farmers who allow their stock to be operated upon; there have been no cases of failure where the instructions for operating have been faithfully executed. Up to the present, two descriptions of virus or pock were necessary to be employed. M. Roux, one of Mr. Pasteur's assistants, has tried a new virus, which insures immunity by one vaccination in place of two; it has been successful everywhere. M. Tayon has conducted experiments with the virus on asses and mules in Africa, but these animals invariably proved rebels to all attempts at "taking" the vaccine. On the 11th May a Congress will be held in Paris to deliberate on the Pasteur principle being extended to other contagious diseases to which stock are liable.

This is more urgent as peripneumonia is the order of the day. Inoculating healthy animals in the tail, with a virus taken from an animal which has just expired, has only yielded mixed results: gangrene attacked the tail, produced from irritation of the wound or from impure virus: the remedy was worse than the disease. M. Pasteur has stated that the peripneumonic virus cannot be "prepared" like that of the *charbon*. However, de Dorpat of Germany has prepared the former free from fatal impurities by heating it pending ten minutes at a temperature of 131° Fr.

Efforts have been made to produce machinery capable of extracting sugar from beet on the farm even, and by the ordinary servants. A firm in the neighbourhood of Paris claims to have supplied the want; practical lessons have been given and with fair success at their works.

M. Marguerite draws attention to the great waste of blood, when it can render such invaluable services as a manure. A preparation of sulphate of iron, one quart to 20 of blood, will convert the latter into a cake, which, when dried, either by pressure or heat, will readily pulverize and contain from ~~10~~ to 12 per cent of nitrogen.

The employment of superphosphates as a complementary manure up to the present found but little favour among tillage farmers of calcareous soils in the south-west of France. M. de Gasparin, the eminent chemist, has investigated the subject, and found that, when the phosphate was scattered on meadow land, so as to be followed by a slight rain or heavy dew, the results were eminently satisfactory. The phosphoric acid in the superphosphate in question was in the state of phosphate of iron; but the acid is as capable of entering into vegetation in this state, as if combined with lime—iron playing an important part in the skeleton of cultivated plants: conclusion: that, in calcareous soils, superphosphates with base of iron answer well—a fact of great importance.

Professor Märcker, of Saxony, recommends manures containing 168 lb. of soluble phosphoric acid, and 66 lb of nitrogen per 2½ acres for potatoes; for sugar beet

* From the confusion in spelling it is impossible to say whether cake of *cacao* (*theobroma*) are meant, or whether the comparison is between oil cake of the African palm and coconut poonac. The latter, we suspect.—ED.

the same dose of acid and double the quantity of azote. Dr. Wildt, of Posen, recommends nearly the same formula.

Brewery mash or refuse constitutes a valuable source of feeding for milch cows, especially when fresh; the difficulty is to keep it from becoming acid, as, when in this state, it affects the milk. Several processes are employed to preserve it, as drying and compressing into cakes, conservation, when well salted, in trenches, &c. At Berlin, a firm has been established which mixes the refuse with bran, flour, peas, beans, &c., making the mass into a paste and baking as bread; the loaves recall in taste and odour fresh rye bread. The preparation readily dissolves in water, or can be mixed with chopped food. All animals relish it, and the milk from cows fed on it is excellent.

M. Roeber, a Swiss gentleman, has improved a winnowing machine for separating clover and lucerne seed from dodder, and which is highly spoken of by independent persons who have witnessed its working. The seed passes through a series of movable drawer screens, and is brought up into a drum after passing through a regulated current of air, which carries off the lighter seeds of the parasite. The machine can be adapted to [illegible] other seeds. A machine has been produced in Hamburg for making "wood wool," suitable for littering purposes, and claiming superior advantages over sawdust. It converts chips of every kind of wood used in workshops into a sort of fibre or flock.

In the south-west of France the sainfoin is attacked with a malady caused by a fungus; applications of sulphur after the first cutting are recommended. M. Chevreul suggests a study of the changes effected in the composition of the soil.

The prospects of the beet crop are very brilliant, and the area of land under the root is this season largely in excess of previous years. For the success of sugar beet, the selection of good seed has become an axiom.

The vines commence to bud and leaf, so that in a few weeks we will be in a position to determine the new progress made by the phylloxera. Vineyard proprietors struggle energetically against the malady. It is proposed to apply the 300,000 fr., voted by the government some years ago for the discovery of a perfect cure, to supplying sulphuret of carbon, &c., at a reduced price. It has been remarked that, when American stocks are employed, care should be taken that their origin will coincide in point of climate with that wherein they are to be employed. The wheat crop is excellent; the only danger to be apprehended is a too rapid vegetation.

TRADE BETWEEN INDIA AND AUSTRALIA.

According to some figures given in a recent number of the *Calcutta Englishman*, the trade between India and Australia is steadily if slowly on the increase. The fact that it is so is no doubt traceable to some extent to the holding of the Sydney and Melbourne Exhibitions. For several years before the Exhibitions were held the little trade there was between the two countries was on the decline. The number of vessels that reached India from Australia in 1877 was 149; in 1879 the number had dwindled to 111. Since that year, however, the tendency has apparently been in the other direction. In 1880 the Indian exports to these colonies were valued at 45 million rupees, while in 1881 their value was 52 millions, and during the last nine months of the official year the estimated value was 71 millions. It of course remains to be seen to what extent this increase is attributable to the temporary excitement caused by the Exhibitions, but it will be the fault of the colonies if the new commercial relationships to which these events gave rise are not fostered and made permanent.

It need hardly be said that the chief Indian export to these colonies is tea. Of this article the exports for 1879-80 were valued at 64,000 rupees, while for 1880-81 it was 515,000, for the nine months ending December last year the value was 548,000. The next item of export is gunny bags, the value of which went up from 35 million rupees in 1879-80 to 56 millions for the last nine months of last year. The value of the raw jute exports also went up from 71,000 rupees in 1879-80 and 94,000 in 1880-81 to 132,000 for the last nine months of last year. 5,491 rupees' worth of myrobalams was also exported during the last nine months of last year, whereas during the previous year there was no such export at all. The other articles which seem to be making headway are shellac, castor oil, saltpetre, linseed, cordage, and rope of vegetable fibre. The exports of coffee and rice seem to be on the decline. In 1879-80 those of the former were valued at 264,000 rupees, while for the first nine months of the current official year their value only amounted to 208,000. The value of the exports of coffee also fell from 84,000 rupees in 1880-81 to 12,000 for the first nine months of last year. It seems also that indigo to the value of 2,240 rupees was exported during 1880-81, while the statistics for the first nine months of last year mention no such export.

From the figures referred to, it will be seen that the trade between India and Australia is an exceedingly fluctuating one, but its tendency, upon the whole, is in an upward direction, and there is no reason why this tendency should not be maintained. The chief difficulty, of course, in the way of any considerable trade between the two countries lies in the fact that these colonies do not produce a great deal that India wants. Our chief export is wool, and India imports very little of that article. It is as a manufacture, and not as the raw material, that India has been in the habit of importing wool, and we find that the total value of the woollen manufactures imported into India during a recent year did not amount to more than about three-quarters of a million sterling. The principal import into India is cotton. More than one-third of the imports of the peninsula consists of articles of this description. It has been stated, however, that an order has been received in Sydney for 50 bales of wool to be worked up into blankets and carpets; and, though with a country, with a climate, and with manufactures like those of India, we may never expect to do a large wool trade, we may open up a trade which it will be our duty to cultivate.

If we are to take the figures of our "Statistical Register," the total value of the trade between this colony and India for the year 1880 was about £20,000, £19,611 of this consisting of exports to India, and only £653 of imports from that country. Of the exports to the value of £19,611, more than £18,000 worth went to Bombay. Hitherto, our contemporary remarks, the dealings of India in the Australian market are limited to a moderate demand for horses, a little copper, and a small demand for fruit. We find, however, that during 1879-80 India took 76,000 tons of our coal. Nor in there any reason why not only our tin and copper, but our frozen meat and our wines, should not find a market in India. At present the most serious obstacle to the trade between the two countries is the cost of freight. Before much is done there will have to be cheaper and better communication. In a maritime review, published a short time ago, it was stated that more than 50,000 cwt. of copper was brought from Australia to India via England. Such roundabout methods of communication as these are fatal to the growth of trade.—*Sydney Morning Herald.*

HORSE-BREEDING IN CENTRAL AUSTRALIA.

TO THE EDITOR OF THE SYDNEY "ECHO."

Sir,—In your issue of the 13th you republish from the *South Australian Advertiser* a very pertinent and telling letter on the above subject. In an official re-

port to the Indian Government, which was sent up some time ago, I made the same suggestion as is made by the correspondent under refer ence. There can be no doubt that there is yet a great future for these immense central plains and countless leagues of apparently "wind-swept desert" as breeding grounds for horses for the Indian market. In physical character they somewhat resemble the Arabian plains, famed for producing some of the finest strains of horse-flesh ever known. In climate they do not differ vastly from the Persian sandy steppes, which produce a hardy, serviceable class of horses. The arid wastes of parts of Scinde, Central India, the Punjaub, and Afghanistan are noted for strains of Caboolee horses and what are called country-breds, which are noted for their good feet, strong frames, powers of endurance, and capacity to keep in good condition on scanty fare. These central Australian plains would produce the very class of horse suitable for India. They would have good bone, splendid feet and clean legs, and excellent wind. They would be inured to heat and accustomed to a dry herbage, and, most important point of all, they would be two weeks nearer India, with the certainty almost of a quick, quiet passage, and would be landed in the pink of condition and be at once ready for service. Under the present system, horses are usually sent up in sailing ships instead of in steamers specially constructed for a live stock traffic. They are generally put aboard by means of slings, subjecting them to the danger of ruptures and hurts instead of being walked aboard on inclined or sloping stages. The length of the voyage brings them down in condition and makes the percentage of deaths or risks of permanent injury unduly large. In consequence, horses landed in Madras or Calcutta have to be fed up and exercised and groomed often for weeks before finding a purchaser. Indeed, many are "cast" by the Government officers simply because it is a question whether they will live or die; and the dealers having to keep the stock till they get into some sort of fair condition adds enormously to the price of the animal. As a rule, a horse in India (an imported horse I mean) gets, perhaps, more luxurious treatment than in any other part of the world, Arabia itself not excluded. He has, generally, a spacious stall or loose box to himself. A *grasscutter* is told off to attend exclusively to his wants, and a *syce* or head groom looks after the grasscuts, and sees that they cut sufficient fodder for the daily supply. It is a common sight near a cavalry cantonment to see long lines of these grasscutters come trudging along the roads in the forenoon, each with his neat pile or bundle of cooch grass on his head, from the roots of which all dust and grit have been carefully washed and beaten. Twice a day the "Waler." or imported Australian horse gets a feed of gram (*cicer arietinum*), probably the finest horsefeed in the world. This is mixed with a few pinches of salt after being soaked in water, and the horse before his feed is generally led out for a "roll," as it is called, which is merely a few miles' walking exercise. A buggy horse rarely is driven more than 8 to 10 miles on a stage; a saddle horse very rarely is ridden more than 12 to 15. Every planter possesses quite a stud; even an assistant generally keeps from three to five saddle horses, a polo pony, and often a buggy nag or two. For a stage the horses are sent on over night, each in charge of his grasscutter; and, as soon as his stage is finished, he is handed over to the man in waiting, who carefully cools him down, covers him with a cloth, and leads him home. Races are frequent in the cold weather. Bookmakers are unknown, and the sport is in the hands of true sportsmen and true lovers of fair racing. A turf scandal is a very rare occurrence in India, although, of course, there are occasionally black sheep to be met with there as elsewhere. I know of no country where horses are better treated, more carefully tended, more highly appreciated, or more valued. The demand is practically inexhaustible; and, were horse-breeding to be gone into on a large scale, on good commercial principles, in Central and North-western Australia, and suitable steamers be provided to ship the stock from the north-west corner of our continent, I feel sure it would prove a most remunerative undertaking. Horses could then be sold somewhat cheaper than the prices ruling at present, which would tend to d uble the demand. Use would be made of vast tracts that are at present allowed to lie unproductive and neglected. The risk of carriage and length of voyage would be minimized, and another great stride would be made in the great policy of binding the outlying portions of the empire more closely together by a community of interests and the ties of commercial intercourse. Many speculations are claiming the attention of investors nowadays that do not present half the promise that an "Indo-Australian Horse Supply Association" presents. We hear of pastoral associations being got up to enable small capitalists to embark in wool-growing and beef-raising. I believe a company, who would take up land in Central Australia, for the purpose of breeding horses for the Indian market, could, or would, be able to get land cheap, breed suitable stock successfully and cheaply, secure large contracts with the Indian army authorities, and find a never-failing market for all the surplus stock they could raise, at highly remunerative prices. I shall be glad if you give some prominence and your powerful support to such a scheme, as I feel assured it has only to be started to become a great success. It would promote settlement, utilize waste land, attract capital and enterprize to the interior, and powerfully promote Indo-Australian trade—a matter which must appeal to every one who has the federation of the empire at heart. *Verb. sap.*—Yours truly, JAMES INGLIS (late Commissioner for India).—[Ceylon like India, will, we suspect, ere long obtain most of her horses from Australia.—ED.]

THE NEW YORK COFFEE EXCHANGE.

Polls will be open from today until Tuesday for the election of officers of the new coffee exchange. The regular ticket which will be elected is as follows:—President, Benjamin G. Arnold; Vice-President, John S. Wright; and Treasurer, John F. Scott. The constitution and by-laws which have just been adopted have been printed for distribution among the members. Among other things these provide that, prior to the 21st day of January 1882, until the number of outstanding certificates of membership shall be 100 the initiation fee shall be two hundred and fifty dollars. On and after the 21st day of January 1882, until there be 200 outstanding certificates of membership, the initiation fee shall be five hundred dollars; and thereafter the initiation fee shall be one thousand dollars; that the assessment for the first year shall be $50, and after that not more than $100; that the governing committee shall elect an arbitration committee of five members whose powers are carefully defined; that the Exchange shall be open from 9 a. m. to 4 p. m. and business shall be confined to those hours, any violation of which shall be punished by a fine of $25; that all parties engaged in handling coffee for members, such as warehousemen weighers and samplers, shall be licensed by the governing committee; that a board of supervisors shall nominate to the governing committee a board of inspectors to consist of five members, and shall supervise the duties of such inspectors. The inspectors shall establish standards of all coffees bought and sold in the Exchange, and enumerate in a clear manner the grades

thereof whenever necessary. They shall also have charge of the grading and classifying all type samples, and shall be entitled to collect for each set so graded and classified five dollars. This board shall hear and decide on all cases of appeal from rejection of coffee on account of quality or condition, and their decision shall be final in so far as it affects any parties in interest who may be represented in the examination of the rejected coffee, or in the arbitration regarding the same, for which they shall be paid by the party in error fifteen cents per package. The by-laws provide a form of contract for sales for future delivery.

Coffee shall be receivable and deliverable in the city of New York, south of Fourteenth street, or within the limits of the port of New York, only from or at such warehouses as may be recommended by the board of supervisors, approved by the governing committee and duly licensed, as provided in sec. 93. Nor shall any delivery of coffee upon contract for future delivery, or to arrive be lawful, unless said delivery is from or at a licensed warehouse, and, unless otherwise stipulated prior to the sale of spot coffee, the buyer may demand that the coffee purchased be delivered from or at a licensed warehouse.

Commission shall be charged and paid under all circumstances, both upon the purchase and sale of contracts for future delivery, and where a "turn" involves two transactions, viz. : purchase and sale, a commission will be charged on both, this rule being equally applicable to extension or transfer of contracts from one month to another. The rates of commission shall be as follows : On packages of eight pounds gross weight or over, eighty cents per package, and on packages below eighty pounds in gross weight four cents per package, when the transaction is made for any party not a member of this exchange. The minimum rate to members of the exchange shall be four cents per package of under eighty pounds, gross weight, except where one member merely buys or sells for another, giving up his principal on the day of the transaction and not receiving or delivering the coffee, in which case the rate shall not be less than two cents for the larger and one cent for the smaller of said packages.

The constitution and by-laws are very elaborate and provide carefully for the government of the Exchange and the transaction of a great business.—New York *Commercial Bulletin*, January 12th.—[The danger will be that this "Coffee Exchange" will degenerate into a "Ring."—ED.]

THE ORIGIN OF CUPREA BARK.

There appears in the *Pharmaceutical Journal* an elaborate paper by JOSÉ TRIANA, a name familiar to those who have studied the literature of the cinchonas, on "THE BOTANICAL SOURCE OF CINCHONA CUPREA." It appears that the *cuprea* bark, so named from its coppery colour, is yielded by a group of plants which stand midway between the true cinchonas and the cascarillas. Triana and Karsten discovered some of these plants, but Triana, noticing botanical characteristics which separated the plants from the cinchonas, never thought of testing the bark for alkaloids. Indeed, until the introduction of this cuprea bark, many held the opinion, that from no plant but the cinchonas could alkaloids be obtained. But it is now found that the bark from two species of *Remijia*, growing plentifully the one in the lower Cordillera of the Andes, which extends to the great plain of the Orinoco and the other in the valley of the Magdalena River, do yield alkaloids although in small quantity. They grow at elevations of 700 to 3,500 feet, in situations warmer and drier than those affected by the true cinchonas. We scarcely see why Triana should suppose that their discovery and the fact that these bushes (for such they are) will grow in dry warm localities are likely to affect cinchona cultivation and the price of quinine very greatly, for cuprea bark contains quinine only at the rate of ·0 to 2 per cent, and it appears that, as in the case of cinchonas, "*the alkaloids increase in proportion as the trees approach nearer to the upper limit of their vegetation and are better protected by the great forest.*" That is, the higher the elevation, the better the quality of the bark, so that the existence of abundance of the plants at low elevations and their capability of being cultivated in lower localities than will suit the true cinchonas need not give those interested in the cultivation of cinchonas the scare which Triana seems to think they ought to feel. The effect of accumulations of this inferior bark in the European markets has not been, as we were able to point out recently, to lower the average price of good cinchona bark, while Triana himself states that the rush into the trade and the stoppage of sales resulting from excess have so operated that "the industry which ought to prove a new source of riches for Columbia, has accidentally become a cause of financial disaster." Agriculture had been neglected in the rush to gather bark which is now unsaleable at remunerative prices. While we follow the advice of Mr. Howard and the other great quinine manufacturers by growing the best species and varieties of cinchonas, we do not think we need greatly fear the competition of cuprea bark, or of other barks in which a bitter principle exists or which may yield minute quantities of alkaloids. For a time it appears a single firm in Bucaramanga in the State of Santander (have our readers ever heard of the place before?) kept the secret and enjoyed the monopoly of the trade in the bark of the *Remijia* plants. But the discovery, and the consequent rush and the overloading of the market, were inevitable. A small portion of the cuprea barks have yielded a new alkaloid called cinchonamine, and the peculiarity of cuprea barks generally is that they yield no cinchonidine. The bark which yields the new alkaloid resembles that of cascarilla, so that the *cinchonas* which yield abundance of alkaloids ; the *Remijias* which yield small quantities, and the *cascarillas* which are so absolutely destitute of alkaloids, are "linked, each to each," by certain affinities : a fresh illustration of the difficulties of defining species There are numerous plants belonging to the genus *Remijia*, but the two species from which the supplies of cuprea bark have hitherto been obtained are *Remijia pedunculata* which Triana himself described and named and *Remijia Purdieana* named after a botanist called Purdie. The trees closely resemble each other, and so do the barks, for Triana states :—

The resemblance between the barks of the two species is also very great and it would be difficulty to find characters sufficiently marked to distinguish them. They are both, in fact, hard, very compact relatively heavy, the inner surface smooth and more or less of a wine-red tint, the epidermis thin or more or less corky, and striated longitudinally. The fracture is not fibrous, as in many cinchonas.

The cuprea bark which yield cinchonamine is, however, heavier and more compact and more filled with red resinous colouring matter, and its fracture generally appears to be horny.

The discovery thus made of febrifuge alkaloids in the barks of a group of plants outside the genus *Cinchona*, as defined by me, renders it necessary to reconsider the characters upon which the genus is founded and to estimate its affinities at their true value.

De Candolle constituted his genus *Remijia* from Brazilian plants which St. Hilaire, in his "Plantes Usuelles des Braziliens," had referred to the genus *Cinchona*, and which had previously been made known by Vellozo under the name of *Macrocnemum*. These plants are shrubs which grow on the dry and exposed summits of the mountains that extend from north to south of the province of Minas, indicating the presence of iron in the soil, according to St. Hilaire.

According to the same author they have bitter barks which singularly resemble those of the Peruvian cinchonas, and bear without distinction the names of *Quina de Serra* (mountain cinchona) or *Quina de Remijio* (the name of the person who first pointed out to the Brazilians their use as a substitute for the officinal cinchonas.)

St. Hilaire, while acknowledging that perhaps, the "Quina de Serra" plants were only varieties of one species, yet referred them to three, called *Cinchona Remijana*, *C. ferruginea* and *C. Vellozii*, and these have been retained by De Candolle under the new name *Remijia*; but I believe, in fact, that they ought to be considered as forms of one specific type. De Candolle, adopting the idea of St. Hilaire, who had called one of these species *Cinchona Remijiana*, in order to preserve the memory of the surgeon Remijo, to whom is due the use of these plants as febrifuges, gave to his genus the name of *Remijia*. This genus is evidently very near to *Cinchona*, and its affinity has been rendered still more close by the discovery of the cinchona alkaloids in the Columbian species of *Remijia*; but it is clearly distinguished from *Cinchona* by its axillary inflorescence, and its capsules debiscing from above downards. In the last character, as well as in the analogy of the structure of their barks, the species of *Remijia* approach more nearly to the genus *Cascarilla*; but from this genus they differ in the prominent and remarkable character of the axillary inflorescence, and also by the presence of alkaloids in their barks, which have not hitherto been discovered in the genus *Cascarilla*.

The genus *Remijia* presents then characters sufficiently well defined and constant to keep it distinct from the two genera most nearly allied to it, viz., *Cinchona* and *Cascarilla*.

The writer then goes on to recognize these plants as somewhat formidable rivals in commerce of the true cinchonas, after a fashion with which we cannot agree. But we let the author of the paper speak for himself:—

The officinal "remijias" of Columbia, as at present known, grow under conditions of elevation, soil, heat and exposure almost the opposite to those which the cinchonas require, and they grow in places only a little above the level of the sea, in the basin of the Magdalena river on one side and in the basin of the rivers Meta, Rio Negro, and Guaviare on the other, without ever reaching the elevated summits of the Cordilleras.

For the cultivation of the species yielding febrifuge alkaloids, whether in their native country or elsewhere, a new and much more extended and varied field is now opened up, and enterprizes of this kind will be more numerous and their success more easy and certain. The officinal "remijias," being more hardy and natives of the lower parts of the mountains, loving warmth and not being affected by drought, will lend themselves more easily to cultivation and more especially in those intertropical countries where the cultivation of the cinchona would be impossible. The cultivation of the cinchonas in the old world will also be affected in consequence.

As to the commerce in bark it has already found in the genus "remijia" new sources of enterprise in the peculiar conditions and circumstances of its vegetation, which are, as already remarked, different from those of cinchona, and these may be still further increased by the possible discovery of febrifuge alkaloids in other known species of the same genus, natives of Brazil, Ecuador and Peru, or in new ones which may yet be found. Probably also investigation will be made of species of other genera allied to cinchona which have long been overlooked.

The answer to all this seems to be that, while cuprea bark is a drug in the market, the bark of the true cinchonas continues in demand at prices the average of which has not been reduced with increased supplies of the true species, and the enormous irruption of the *Remijia* or cuprea barks.

THE BOTANICAL SOURCE OF CINCHONA CUPREA.

BY JOSE' TRIANA.

Since the publication of my "Nouvelles Études sur les Quinquinas," Dr. Hesse has remarked the appearance in commerce of a new bark which differed from those of all known cinchonas in its aspect, density, texture and colour, etc., but which contained alkaloids characteristic of the true cinchonas. Subsequently, Professor F. A. Fluckiger, in the *Neues Jahrbuch f. Pharmacie*, xxxvi.- 296, stated that the same bark differed considerably from the cinchona barks in its anatomical structure, which he compared to that of *Cascarilla magnifolia*, and gave to the new bark the name of cuprea cinchona, on account of the dull coppery tint of its external surface.

During the last few years especially there have been introduced into Europe considerable quantities of new barks, which have maintained in commerce the name of "cuprea bark," and the importations have been so large that the price of all cinchona barks and of sulphate of quinine have been very sensibly lowered.

The chief emporium and centre of exportation of the cuprea barks is Bucaramanga, in the State of Santander, and the trees which yield them are found in abundance in the mountain chain of La Paz, which breaks off from the great eastern branch of the Columbian trifurcation of the Andes, and runs parallel to the course of the Magdalena river, separating it from its affluent, the Suarez. At first there was one firm in Bucaramanga which exported the bark, and by keeping secret the use to which the bark was destined, it succeeded for some time in maintaining a kind of monopoly. But attention having been roused by the regular exportation, it at length became known that these barks were considered to be the produce of cinchonas, and were much valued in Europe; from that time an eager search was made for them, and their exportation soon assumed such proportions that the bark market became rapidly overloaded and supplied with sufficient to last for a long time.

The impetus having once been given, the search for cuprea bark was prosecuted in other forests of Columbia, and barks quite equal to those of Bucaramanga were found towards the base of the great eastern branch of the Cordillera of the Andes, and as far as the great plain which extends to the Orinoco, and in the valleys of the rivers Meta and Guaviare, affluents of the river

Orinoco, and these barks pass in commerce under the same name as those first discovered.

The cuprea bark at present in commerce is therefore furnished by two very distinct regione : the one, just described, in the great basin of the river Orinoco, to the South of Bogota, and the other, which was the one first explored, in the lower part of the basin of the Magdalena river.

Amongst the numerous cuprea barks received from Bucaramanga, or the northern region, there is occasionally found a relatively small quantity, which has been discovered by M. Arnaud to be peculiar in containing, in place of quinine, a new alkaloid which he has called cinchonamine.

Professor Planchon has also observed that the anatomical structure of the bark containing cinchonamine differs from that of ordinary cuprea bark, and has compared it to that of a *Cascarilla*. He concludes that if the cuprea barks have characters in common which place them outside the genus *cinchona*, they also present between themselves such differences that they ought to be considered to form specifically distinct types.

Hitherto, the plant or plants which produce cuprea barks have been unknown to science, although the barks have taken so considerable a place in commerce and in the manufacture of sulphate of quinine. Desiring to fill this gap from a botanical point of view, I made strenuous efforts to obtain in Columbia specimens of the plants yielding the cuprea barks, and my efforts have been in great measure crowned with success. I have just received documents from the two centres of collection above named, which now enable me to determine and classify the trees which furnish the cuprea cinchona, and to establish their botanical nomenclature. This classification, and other facts shortly to be mentioned, raise points which seem to me to be of the highest interest in relation to science, commerce, and the cultivation of cinchonas, and to these point I have now to call attention.

The barks distributed in commerce at the present time under the name of cuprea bark are afforded by two distinct districts. They also belong respectively, at least, to two distinct species which, though nearly allied, are yet different from each other and belong to the genus *Remijia*, which comes very near that of *cinchona* and to the closely allied genus *cascarilla*. These species are *Remijia Purdieana*, Wedd. (*Ann. Sc. Nat.* [3], xi., p. 272), a plant formerly discovered by Purdie in the forests of Antioquia, upon the left bank of the Magdalena : and *Remijia pedunculata*,, Triana (*Cinchona pedunculata*, Karsten, "Spec. Select.," i., 53, t. 26).

My identification of the tree from the valley of the Magdalena river is founded upon the only samples that I have received of the cinchonamine-yielding sort, which are identical with those of Purdie. I incline to believe that all the other cuprea barks said to come from Bucaramanga, notwithstanding the difference in their chemical composition noticed by M. Arnaud and the not less remarkable difference in their anatomical structure indicated by M. Planchon, can only be produced by the same botanical species, viz., *Remijia Purdieana*; inasmuch as (1) the barks containing cinchonamine have been exported to Europe as being those of cuprea, without any distinction being made between them, except in remarking that the trees from which the bark was obtained grow in a warmer locality at a lower elevation than the others, without, however, indicating that they might be different among themselves ; and (2) if the trees worked in the northern districts be distinct, the resemblance between the one which is most abundantly exported from Bucaramanga, and which must have been used as a standard of comparison to discover the cuprea bark in the south, would be less than that which exists between *Remijia Purdiena* and *R. pedunculata*, which is very great at first sight.

The difference in the conditions of vegetation where the trees yielding the two kinds of cuprea bark of Bucaramanga grow would suffice, it seems to me, to explain the change in the nature of the alkaloids and the modifications in anatomical structure observed in them. In any case this is a question that I hope I shall be able to solve when samples of the common cuprea of Magdalena, which I am expecting to receive shortly, shall have arrived. But there can be no doubt that if these trees are distinct they must belong to very closely allied species of the same genus.

With regard to the southern district, I am in possession of specimens gathered at Susumuco, Villavicencio, Papamene and on the banks of the Guaviare, etc., localities distant from each other and varying in elevation above the sea level from 200 to 1,000 metres. Notwithstanding slight variations, which cannot be considered as specific characters, all these specimens answer to *Remijia pedunculata*, Triana, a species discovered by M. Karsten and myself between Susumuco and Villavicencio, and of which my fellow-traveller has published a description and a fine figure in the 'Specimina Selecta.'

The two Columbian species of *Remijia*, which yield the cuprea barks, have, at first sight, a very great resemblance, in habit, in the form, size and smoothness of the leaves, in their inflorescence, and in their capsules of almost the same size; they are in reality, however, very distinct and are easily characterized.

Remijia Purdieana has the divisions of the calyx lanceolate-acute, almost linear, and much longer than the tube of the calyx. Thr stipules are lanceolate-acute and the capsules are also lanceolate.

Remijia Pedunculata has the teeth of the calyx small, triangular and almost rounded at the apex; the stipules are obture, broad and obovate, and the capsules are shorter than those of *R. Purdieana*, which are elliptic.

The resemblance between the barks of the two species is also very great and it would be difficult to find characters sufficiently marked to distinguish them. They are both, in fact, hard, very compact, relatively heavy, the inner surface smooth and more or less of a wine-red tint, the epidermis thin or more or less corky, and striated longitudinally. The fracture is not fibrous, as in many cinchononas.

The cuprea bark which yields cinchonamine is, however, heavier and more compact and more filled with red resinous colouring matter, and its facture generally appears to be horny.

The yield of quinine from cupred barks varies between ·0 and 2 per cent., according to the conditions of vegetation of the trees, which have not yet been sufficiently studied. In this respect they resemble the officinal cinchonas. In both cases it appears that the alkaloids increase in proportion as the trees approach nearer to the upper limit of their zone of vegetation and are better protected by the great forest.

From a chemical point of view, the characteristic and remarkable feature with distinguishes the cuprea barks from the true cinchonas is the absence of cinchonidine, which has been ascertained by numerous analyses made by M. Arnaud, confirming the results obtained by other chemists.

In cuprea barks, quinidine would also be always proportionately more abundant than in other cinchona barks, which would permit the formation of the double salt of this alkaloid with quinine, and would produce, according to Mr. C. H. Wood and Mr. E. L. Barret (*Chemical News*, vol. xlv., p. 6, and *Moniteur Scientifique*, 3rd ser., xii., p. 148), the new supposed alkaloid, the discovery of which was announced almost simultaneously in England by Mr. D. Howard and Mr. J. Hodgkin, on the one part, and by Dr. E. H.

Paul and Mr. Cownley, on the other part, under the names of "homoquinine" and "ultraquinine."*

Nevertheless the existence of cinchonamine, the new alkaloid studied and isolated by M. Arnaud in certain cuprea barks, remains unquestioned.

The discovery thus made of febrifuge alkaloids in the barks of a group of plants outside the genus *Cinchona*, as defined by me, renders it necessary to reconsider the characters upon which the genus is founded and to estimate its affinities at their true value.

De Candolle constituted his genus *Remijia* from Brazilian plants which St. Hilaire, in his "Plantes Usuelles des Brasiliens,' had referred to the genus *Cinchona*, and which had previously been made known by Vellozo under the name of *Macrocnemum*. These plants are shrubs which grow on the dry and exposed summits of the mountains that extend from north to south of the province of Minas, indicating the presence of iron in the soil, according to St. Hilaire.

According to the same author they have bitter barks which singularly resemble those of the Peruvian cinchonas, and bear without distinction the names of *Quina de Serra* (mountain cinchona) or *Quina de Remijio* (the name of the person who first pointed out to the Brazilians their use as a substitute for the officinal cinchonas.)

St. Hilaire, while acknowledging that, perhaps, the "Quina de Serra" plants were only varieties of one species, yet referred them to three, called *Cinchona, Remijiana, C ferruginea* and *C. Vellozii*, and these have been retained by De Candolle under the new name *Remijia*; but I believe, in fact, that they ought to be considered as forms of one specific type. De Candolle, adopting the idea of St. Hilaire, who had called one of these species *Cinchona Remijiana*, in order to preserve the memory of the surgeon Remijo, to whom is due the use of these plants as febrifuges, gave to his genus the name of *Remijia*. This genus is evidently very near to *Cinchona*, and its affinity has been rendered still more close by the discovery of the cinchona alkaloids in the Columbian species of *Remijia*; but it is clearly distinguished from *Cinchona* by its axillary inflorescence, and its capsules dehiscing from above downards. In the last character, as well as in the analogy of the structure of their barks, the species of *Remijia* approach more nearly to the genus *Cascarilla*; but from this genus they differ in the prominent and remarkable character of the axillary inflorescence, and also the presence of alkaloids in their barks, which have not hitherto been discovered in the genus *Cascarilla*.

The genus *Remijia* presents the characters sufficiently well defined and constant to keep it distinct from the two genera most nearly allied to it, viz., *Cinchona Cascarilla*.

By the chemical composition of their barks, the "remijias" must now take an important place in commerce and in therapeutics by the side of the cinchonas, of which they are becoming rivals, which confirms the foresight of Remijo and St. Hilaire. Henceforth the two groups of plants will be coupled together, and as the name *Cinchona*, given by Linnæus to the tree of which the bark cured the Countess of Chinchon, will recall this fact, that of *Remijia* will preserve an analogous one from being forgotten.

Beside the generic characters which I have defined, the original species of *Remijia*, as well as those subsequently published, have, as De Candolle remarks, "a peculiar stamp which distinguishes them at first sight from the cinchonas, and which consists of a shrubby habit, in the leaves being sometimes in whorls of three, particularly the lower ones, in the branches and inflorescence being covered with a reddish pubescence, and in the quadrifid woody capsules." But these distinctions, due to collateral circumstances, diminish in other species, especially in the two Columbian species herein noticed. Their glabrescent foliage, and especially their coriaceous, bipartite and relatively small capsules, give them a considerable resemblance to several of the officinal cinchonas. It is more than probable that it is to this similarity that the discovery of cuprea cinchona, which has undoubtedly been made by persons without scientific qualifications, is due. Perhaps a botanist would have done as I myself did, when I discovered *Remijia pedunculata*, and would have refused to admit this tree among those whose barks yield alkaloids, because it could not be ranked among the true cinchonas, and does not correspond in habit with those whose bark abounds in alkaloids.

From the above remarkable facts, there must follow results of the greatest importance to science, cinchona cultivation, commerce and therapeutics.

From a botanical point of view, several ideas concerning cinchonas, which were considered to be sufficiently established, must be greatly modified. For instance, it has been customary to consider that the presence of alkaloids in cinchona as exclusively characteristic of the plants of the genus as hitherto limited, and there have been those who have gone so far as to say that the chemical analysis might serve to control botanical classification, since alkaloids have never been discovered in the genus *Cascarilla* or in other genera allied to *cinchona*.

It is also admitted that the tress yielding febrifuge alkaloids, especially those of Columbia, as I have stated in my 'Nouvelles Etudes,' grow in the elevated regions of the Cordillera of the Andes, where the temperature is mild with scarcely any cold, and prefer the western slopes of the great eastern branch of the trifurcation of the Andes, the other two branches being almost destitute of them.

Since the number of alkaloid-yielding cinchonas has been augmented by the addition of some species of *Remijia* these plants, regarded as a whole, offer peculiarities worthy of remark, both as to their habitat and their geographical distribution.

The officinal "remijias" of Columbia, as at present known, grow under conditions of elevation, soil, heat and exposure almost the opposite to those which the cinchonas require, and they grow in places only a little above the level of the sea, in the basin of the Magdalena river on one side and in the basin of the rivers Meta, Rio Negro, and Guaviare on the other, without ever reaching the elevated summits of the Cordilleras.

For the cultivation of the species yielding febrifuge alkaloids, whether in their native country or elsewhere, a new and much more extended and varied field is now opened up, and enterprizes of this kind will be more numerous and their success more easy and certain. The officinal "remijias," being more hardy and natives of the lower parts of the mountains, loving warmth and not being affected by drought, will lend themselves more easily to cultivation and more especially in those intertropical countries where the cultivation of the cinchonas in the old world will also be affected in consequence.

As to the commerce in bark it has already found in the genus "remijia" new sources of enterprise in the peculiar conditions and circumstances of its vegetation, which are, as already remarked, different from

* Mr. Triana appears to have overlooked the fact that Mr. T. G. Whiffen also made known the discovery of a new alkaloid, to which he gave the name "ultraquinine," and which was probably the same as that referred to by the other observers. (See before, p. 497.) As regards the suggestion that this alkaloid is really a compound of quinine and quinidine we are still without any evidence in support of its probability or of the existence of such a compound.—ED. P. J.

those of cinchona, and these may be still further increased by the possible discovery of febrifuge alkaloids in other known species of the same genus, natives of Brazil, Ecuador and Peru, or in new ones which may yet be found. Probably also investigation will be made of species of other genera allied to cinchona which have long been overlooked.

I have already remarked that the enormous exportations of cuprea bark that have been made recently have produced a disturbance in commerce, which has lowered the price of the officinal cinchonas in general and of sulphate of quinine in particular, by the accumulation in Europe of barks intended for the manufacture of sulphate of quinine and by the temporary stoppage of the exportation of cinchona barks. This paralysis of business is aggravated in Columbia by the temporary neglect of agriculture, the collection of the cuprea bark proving much more lucrative, and also by the stagnation of capital represented by the value of the bark warehoused abroad, and which is usually held as a balance to meet the cost of imported goods. It happens, therefore, that the industry which ought to prove a new source of riches for Columbia has accidentally become a cause of financial disaster.

It may be hoped that this situation cannot last long, and that by degrees an equilibruim will be established. Commercial men will become more prudent and what is of more significance, the cuprea barks will be diminished in quantity in proportion as the sources of production, already rapidly undergoing devastation, become more exhausted, and the difficulty in collecting the bark becomes greater, as has been the case with the officinal cinchonas.

Finally, the investigations of the therapeutic properties of the new alkaloids or compounds of alkaloids discovered in the cuprea barks will present considerable interest. It now appears more than probable that these alkaloids or their compounds have passed unnoticed mixed with sulphate of quinine in the manufacture of this substance on a large scale.

The following is a list of the species of *Remijia* :—

Remijia Hilairii, D.C. (Prod., iv., p. 357).—*Syn.* Cinchona Remijiana, St. Hil., Pl. us. Bras.; Cinchona Vellozii and Cinchona ferruginea, D.C.; Remijia Velozii and Remijia ferruginea, St. Hil., *l.c.*; Macrocneum, Vell.

This species grows in dry and barren places on the mountains of the province of Minas.

R. paniculata, D.C.

A little known plant; a native of Brazil.

R. Cujabensis, Wedd. (Hist. Nat. des Quinq.), 93 adn.—*Syn.* Ladenbergia Cujabensis, Klotsch in Hayn. Arzneigewachse, xiv.

This species inhabits forests in the neighbourhood of Bahia, in Brazil.

R. Bergeniana, Wedd., *l.c.*—*Syn.* Cinchona Bergeniana, Mart. in Linn., vi; Litt. Ber., 67; Ladenbergia Bergeniana, Klotsch, *l.c.*

A species indigenous in Brazil.

R. firmula, Wedd, *l.c.*; Ladenbergia firmula, Klotsch., *l.c.*

A native of the banks of the Rio Negro, in Brazil.

R. macrocnemia, Wedd.—*Syn.* Cinchona macrocnemia, Mart. Walp. Repert., ii., p. 507; Ladenbergia mecrocnemia, Klotsch, *l.c.*

The species grows on the banks of the Amazon in Brazil.

R. densiflora, Benth, and Hook, Lond. Journ. Bot., iii., p. 215.

A native of English Guiana.

R. hispida, sp. n. in Herb. Spruce, No. 3,248.

Grows near Esmeralda, on the Orinoco River.

R. tenuiflora, Benth., *l.c.*

A species which is found between Barra and Barcelos, on the Rio Negro in Northern Brazil.

R. Purdieana, Wedd. in Ann. Sc. Nat. (3 ser.), xv., p. 272.

This species, which is one of those yielding the cuprea cinchona bark, grows in the forests of both banks of the lower Magdalena, in Columbia, in the provinces of Antiquia and Santander.

R. pedunculata, Triana, Nouv. Etudes.—*Syn.* Cinchona pedunculata, Karst., Specim. Select., i., 53, t. 26.

This species, which also furnishes the cuprea cinchona of commerce, grows between 200 and 1,000 metres above the level of the sea, on the eastern slopes of the eastern Cordillera, on several affluents of the Orinoco and Amazon rivers, such as the Rio Mesa, Rio Negro, Guaviare, Papamene, Zarapote, ect.

"A PERFECT CURE"—FOR COFFEE LEAF DISEASE.

If heroic treatment can effect a cure, we have the recipe before us. Let us imagine a human being suffering from a cutaneous disease, say ringworm. The doctor is called, and his prescription is: "Pull out every hair from the head, and then scrape all the skin from the body, in order that both may be burned. Then anoint the bared frame with my mixture, and look out for a fresh head of hair." The sanity of the doctor would naturally be doubted, but equivalent treatment is seriously recommended for the coffee plants, by gentleman who are particularly anxious that their interests should be protected.

When the senior editor of this paper was acting as Commissioner at the Melbourne Exhibition, he formed the acquaintance of a gentleman, who, formerly a coffee planter in Coorg, was then a reporter on the staff of the *Age* newspaper. As such it gave us pleasure to aid Mr. Gilbert Geo. Smith in preparing an account of the Ceylon Court for the paper he represented. By last mail we received a letter from Mr. Smith requesting us to ascertain and let him know the results of a specific for leaf-disease which Mr. Smith and his partner Mr. Ball had sent to the Ceylon Planters' Association of Ceylon for test. Mr. Smith added that he had found the substance useful during his career as a planter in Southern India. We referred the letter to the Secretary of the Association, and this morning we had a reply which astonished us, as it will those of our readers whose knowledge of vegetable physiology leads them to believe that a tree denuded of all its bark will as surely die as will the man whose brains are out. Mr. Philip courteously wrote to us :—

"The Committee of the Planters' Association was prepared to arrange to give Mr. Smith's specific for leaf-disease a trial until receipt of the enclosed (copy) letter, with the directions which, as you can understand, rather amazed it.

"The case of anti-coffee-blight has now arrived, having cost say R15 for freight, and I fancy the Committee will be glad to hold it at Mr. Smith's disposal."

We should think so, for here are the directions :—

Melbourne, 96, Swanston St., 12th Feb. 1882,

A. Philip, Esq., Secretary, Planters' Association,

Kandy.

SIR,—We beg to inform you that by this steamer we have sent a case of the anti-coffee blight to care of P. & O. Company's Agent, Galle.

We desire you to be kind enough to inform the gentlemen—who will use the specific that it is absolutely necessary to adhere as strictly as possible to the following instructions :—

First.—Strip the infected plant entirely of *all* its foliage, then scrub it with a piece of coir, until all the bark is removed. Care should be taken to re-

move the bark under the notches and in crevices. Some matting should be placed under the plant to catch all the leaves, bark, twigs, &c., which are tobe burned.

Second.—Obtain a quantity of the most decomposed manure—cowdung preferred—and mix with it the specific, until it is reduced to a thick paste; then further reduce it with *water*, until it arrives at a consistency of treacle.

Third.—Rub the compound thoroughly into the plant until it adheres to it. *See that it reaches to every part of the plant*, previously removing all decayed wood that may be on the tree.

Fourth.—Apply the preparation thoroughly, unless it be washed off by rain or rubbed off by accident, in which case give another application.

In about a month's time the new leaves will begin to shoot out and the plant will then rapidly assume a healthy appearance

Do not be afraid of this treatment. It may appear harsh and novel to you, but we can assure you that the very best results have ensued from past experiments.

We would again request you, as the representative of the Planters' Association, to see that our interests do not suffer by our absence, and that you will inform us from time to time as to the progress it (the test) is making.

We are informed that a reward is offered for a cure of this disease. In event of success then, we shall leave ourselves to the honor of the coffee Planters' Association.—Yours truly, GILBERT GEO. SMITH,
M. BALL.

Our readers will observe that the trees to be operated on are to be deprived of *all their leaves*, besides a certain proportion (not stated) of the twigs, and *all their bark*. That the whole of the bark is meant and not merely the epidermis, is obvious from the remarks which follow about not being alarmed at the severe nature of the treatment. It had previously been carried out and the effects were good. We should have thought the effect would have been that the disease would have been cured as the patient's fever was. The fever went off, but he went off with it.

We can assure our readers that Mr. Smith, who is now sub-editor of a newspaper, shewed no sign of mental eccentricity on the occasions when we saw him. He was a quiet gentlemanly man and did not look like a subject for the Yarra Bend Asylum. But of Mr. Ball we know nothing.

We could have understood all the foliage coming off (although the young leaves would be equally liable to be infected), and we could have seen reason in rubbing off all the rough outside bark; but when we appreciated the fact that the directions are to deprive the tree of *all* its bark, our gravity gave way and we afforded some reason for questioning our own sanity by our repetition of "A perfect cure!"

IN damp retentive soils, young cinchona plants are prone to die off in large numbers, and to give very little notice of the advance of decay. Whole acres of fine, healthy-looking young cinchonas suddenly droop, and little is gained by working for a change in the weather, for it fails to produce a revival. A planter gives a hint which seems worthy of attention. He says that, as soon as you observe the drooping of the plants, cut a two foot hole on the lower side, and as near the stem as possible. The hole probably lowers the water level, and thus saves the plant. The remedy is not likely to prove successful, if the plants have been raised from immature seed.—*South of India Observer.*

"FOREST RANGERS."—The Government of India have established a Forestry School in the Dehra Dun at which it is hoped some 600 natives will be speedily fitted for the duties of "Forest Rangers." We presume our own Forest Department needs subordinate officers of the class referred to. Has our Government sent any natives of Ceylon to be trained in the Himalayan Forest School, or in the Agricultral College at Madras?

LABOUR IN JAMAICA.—Mr. Morris recently wrote to say there was abundance, but the question is one of the wages, and each paper from Jamaica shows that the people are going to work on the Panama Canal and on South American railroads. We quote as follows from *Gall's News Letter*:—We learn that the contractors for the Costa Rica railroad, who have all along obtained labour from Jamaica, have now adopted the less expensive plan of sending to Colon for the unemployed Jamaican labourers there.

TEA AND COFFEE DUTY.—A bill is now before Congress (U. S.) to exempt from all discriminating duties tea and coffee produced in the Dutch Colonies. The law as now enforced provides for a discriminating duty of 10 per cent. on tea and coffee grown east of the Cape of Good Hope in the Dutch Colonies, in view of corresponding Dutch duties. As the latter have been repealed, the United States is called on to do so also. It will tend to flood this market with a poor quality of Java coffee, which is generally badly adulterated before leaving the colonies. The Rio merchants strongly object.—*Gall's News Letter.* [Naturally; but what right have the Rio merchants to complain because the United States Government abolish discriminating duties?—ED. C. O.]

THE ASBESTOS PAINT promises to be a complete success, to judge by the experiments recently made at the Crystal Palace. The experiments were of various kinds and the tests applied could not be accused of any want of severity. Logs of wood, partly painted and partly unpainted with the asbestos preparation, were placed on a fierce fire burning in a large brazier and subjected for many minutes to the full force of the flames, fanned by a moderate breeze which was blowing at the time. When they were pulled out by the attendants, the parts which had been painted were seen to be blistered in places and to be emitting at first some light jets of flame, which, however, almost immediately extinguished themselves when the action of the surrounding fire ceased, leaving the surface almost as white and uninjured as before the fire had been applied, whereas those logs, which had been unpainted, or only partially painted, were, of course, charred and almost consumed. The most interesting experiment was, however, afforded by the four wooden structures which had been erected on the terrace, in imitation of theatres and sheds. In the centre of each of these was lighted a vigorous fire fed with shavings soaked in petroleum and burning immediately under the flooring. While the structure which was unpainted blazed up and was soon burning merrily in all its parts, those which had been painted stood the test most conclusively and were hardly marked after about half an hour's trial, when the unpainted sheds were a mere mass of smouldering embers. It was clear to all the spectators that the resistance offered by the paint is most obstinate and certain, and that the great difficulty which the flames have in getting any hold at all upon any substance covered with it would, at any rate, afford a long respite, during which the fire engines would not only have time to come up, but also an audience retaining any presence of mind would be able to escape. The directors of the Crystal Palace Company have already caused their theatre to be covered with the paint.—New York *Hour.*

Correspondence.

To the Editor of the Ceylon Observer.

SALES OF CEYLON COFFEE AT GOOD PRICES.

Edinburgh, 12th April 1882.

DEAR SIR,—I have read with interest in your *Weekly*, of 21st March, a short note from "E. J. T." giving a quotation of fine prices realized for Stockholm estate coffee, so:—1c 1b 113s; 9c 1t 99s 6d; 2c 1t 107s 6d; and 1c 1t 67s. Prices received for the North Pundaloya coffee fully come to this. Take a shipment, ex Quetta, thus:—1c 1b 113s; 1c 1b 109s; 1c 1b 104s 6d; 9c 99s; 9c 90s; and 1c 102s: ex Dorunda, 1c 110s; 6c 2b 100s; 1c 103s; and 3c 1b 96s 6d: ex Duke of Buckingham, 4c 102s 6d; 4c 101s; and 24c 90s. "E. J. T." states that the prices he gives will shew that "Ceylon coffee can hold its own against the world." I will go further than this: I say that our fine Ceylon coffees can *beat* any other—produce it where they may—which is proved by these good samples continuing to realize such fine prices, while the European stocks are so heavy and prices for middling and inferiors have fallen so heavily. Superior preparation, both on the estates and in Colombo, I have no doubt, has a good deal to do with good prices, and it would be interesting to all connected with coffee, advantageous both to managers and curers, if planters could give increased publicity in your columns, as to the results of their sales.—Yours truly,

P. D. MILLIE.

MR. A. SCOTT BLACKLAW ON COFFEE PLANTING PROSPECTS:

PRODUCTION IN BRAZIL ARRESTED; WHILE CONSUMPTION IN THE UNITED STATES IS YEARLY INCREASING.

Dollar, 12th April 1882.

DEAR SIRS,—I am much pleased with the way you have turned out my letters; you must have had some difficulty in the editing of them. My facts were taken from good authorities, and can be relied on, but the putting of them together was generally rather hurriedly done, always at the last moment before the mail left. Living here out of the coffee world I do not know how the letters may have been appreciated by those more immediately interested, the proprietors of coffee estates in India and Ceylon. Your last come *Observer*—that of March 11th—contains the last two of my letters.

Possibly I may have said too much. There are some things better to be left unsaid, and I do not think my exposition, of the ease with which Brazil can produce and send to Europe and the United States such large coffee crops will meet with the approval of everyone, considering the straits many Ceylon coffee-planters are in, first from the effects of leaf-disease on their plantations; and second, the low price of coffee brought on by Brazil's large crops. While in London, two months ago, I put myself to the trouble to call on the Consul-General of the United States in London to get information on the increase of population in the United States during the last thirty years; in other words, during the time that the consumption of coffee has been steadily increasing. Brazil's coffee crops are consumed principally in the United States. When the crops of Brazil are larger than can be consumed in the United States, the surplus finds its way to Europe, and the price of Ceylon and Java coffees comes down. Considering that, owing to the stoppage of the inter-provincial slave trade in Brazil, the coffee crops there will not be larger than they are now, we might expect that, as the population of the United States increases, so the consumption of Brazilian coffee and the present surplus that is now being sent to Europe will follow the regular course as of old, and be sent to North America. Ceylon, East India and Java will then, as before, supply the European markets.

The Consul-General was very obliging, and, although I could not get returns as to the consumption of coffee in the States, he kindly furnished me with particulars as to the population. Here are the figures:—

1860 the population was		31,443,331
1870	...	38,558,371
1880	...	50,000,000

Emigration to the United States last year reached a total of 776,000, and at present it is going on at a larger proportion. We may safely calculate on an increase of 25 per cent of the population in the next ten years.

I leave you or some of your correspondents to work up the figures. I think one could get data sufficient to go upon by studying the coffee prices current. Coffee planting has got a future. I do not think the Ceylon planters should lose patience by considering the present price of coffee as likely to last.

I hope the experiments now being made to try to get rid of the leaf-disease may be successful. A cure for that will help Ceylon more than a rise in the price of coffee.—I am, yours very truly,

A. SCOTT BLACKLAW.

HYBRIDITY.

May 4th, 1882.

DEAR SIR,—I think your correspondent "X.," in the *Observer* of 2nd instant, is in error when he assumes—by asking the question—"do, or do not, rabbits and hares cross freely?" Domesticated they may, but in their natural state it is comparatively rare, if not altogether unknown. The dog and fox, however, have often been known to cross. In that case, one at least is in the natural state, proving hybridity possible.

In the vegetable kingdom, how about *diœcious* plants? Are we told they never fructify naturally? if they do, then why not hybridity?—Yours faithfully,

SI VERUM SCIRE VIS.

THE CINNAMON TRADE.

8th May 1882.

SIR,—Referring to the discussion now going on as to the effect of the trade in cinnamon chips or the price of quilled cinnamon, I find from your Directory that the exports for the year ending the 30th Sept. 1880 amounted to 474,484 lb of chips as against 1,395,534 lb bales. It will thus be seen that the out-turn of chips is over one-third of quills, considerably more than a planter allows, and there can be no doubt that the withdrawal of this enormous quantity of chips from the market must beneficially affect the price of quills. It is, alas! perfectly true that the sale of chips leaves only four or five cents per lb, after deducting the cost of scraping; and the apparently higher prices realized in the London market just suffice to cover the heavy charges. The demand for chips is always reported brisk and steady in London, and it seems only reasonable to infer that in the absence of chips there would be more inquiry for quills. If this results in price advancing by one-third of four or five cents (say 1½ to 2 cents) we should not lose by throwing away our chips; but I anticipate the rise in price will be considerably more. It only requires that my fellow-proprietors should see the matter in this light to secure the practical abolition of the trade in chips and steady rise in prices. "A Merchant," in reply to "Planter," in a late issue of the *Observer*, suggests local sales as a means of doing away with the middle-

men, who, by means of quarterly sales, and otherwise, swallow up so large a share of the profits which should go to the producer. If local sales do away with two classes of middlemen, how comes it that "Merchant" makes no higher offer than is represented by London prices? If growers failed to realize in London at least as much as they do here, I hardly think they would continue the practice of shipping on their own account. We seek to do away with middlemen, not as such, but as absorbents of our profits. "Merchant" proposes to do away with the middlemen, only to put their profits into his own pocket; otherwise, he would pay us London prices *plus* the profits of the middlemen, or at least of as many of them as he does away with.

Again, there is this to be observed, that "Merchant," under the guidance of interested brokers, offers the same for well-known brands which fetch over over 2s in London as for bark which sells at 1s 6d. The result is that small-holders sell to the native emissary, who sells to the merchant, rather than to the merchant direct; for the native gentleman pays a high price to mix with inferior stuff and sell to the merchant. If merchants deal direct with responsible men willing to let their marks be used, the result is likely to be satisfactory to both parties.—Yours truly,

PROPRIETOR.

WAVES OF PROSPERITY SUCCEEDING DEPRESSION: MAURITIUS AND CEYLON.

Colombo, 9th May 1882.

DEAR SIR,—The date is not so remote that it is difficult to recall the time, when the state of agriculture in the Mauritius was synonymous with ruin. The accounts of the Ceylon Company, Limited, published from time to time, furnish ample evidence of the losses sustained by the precipitate realization of sugar estates, of which it had one way or another become the owner.

No sooner had the Company realized their properties at the lowest point of depression than the tide changed. A couple of seasons favorable for agriculture smiled on the island, and the tide of prosperity began to follow. A short time ago, you published an extract from a Mauritius paper, shewing the wonderful enhancement that had taken place in the value of estates, in consequence of their having become the property of more intelligent persons. This change was not brought about by the increased value of the staple product, but simply by a change of seasons! By the enclosed cutting from the overland edition of the *Merchants' and Planters' Gazette* you will see that the prospect of a favourable season for the coming crop has further increased the wave of prosperity, and everything in the Mauritius has a roseate hue.

Is this not a warning to Ceylon planters and mortgagees, many of whom are, I believe, about to commit pecuniary suicide by abandoning or neglecting the cultivation of estates, which only three or four years ago were considered a mine of wealth, because their maintenance may add some small addition to the money already invested? In Mauritius prosperity was dependent upon one staple product: here, in the majority of cases, we have two, and in many three or more.—Yours truly, MERCATOR.

A NEW USE FOR MANIOC OR CASSAVA.

Puttalam, 9th May 1882.

DEAR SIR,—I beg to forward, for your information and that of your readers, the following extract, which I have obtained from the *Scientific American*, December 31st, 1881, and trust that it may be of some use to those interested in "cassava," or those wishing to try new products.—Yours, BOSTON.

(Extract referred to.)

A NEW SOURCE OF GLUCOSE.—A company has been formed in Philadelphia to manufacture glucose from cassava, the source of tapioca. As at present manufactured from corn, the average yield of corn being taken at 35 bushels to the acre, the glucose product is about 1,000 pounds to the acre. The yield from cassava is reckoned to be fully twenty times as great. The company's expectation will doubtless bear considerable paring down. They say that well authenticated evidence is at hand to the effect that 20 tons of of cassava to the acre is no unusual crop in Florida. This, at 56 pounds to the bushel, would give give a yield of over 700 bushels per acre, or, at the rate of 30 pounds of glucose per bushel, would produce over 21,000 pounds of glucose per acre. A comparison of the yield of glucose from corn, and cassava shows that 1,000 acres of corn yields about 500 tons of glucose; 1,000 acres of cassava yields about 10,000 tons of glucose.

[We had seen this statement, and meant to draw attention to it, as important to lowcountry planting in Ceylon. When we visited what is probably the largest cassava plantation in the world, the property of a French gentleman at Singapore, he told us that supply had outrun demand, and that he had a heavy stock of well-prepared cassava in London. If the statement now made turns out to be correct, Ceylon planters may be able to take a share in supplying with glucose the breweries of the world, including that just started at Nuwara Eliya.—E.]

SALES OF FINE COFFEE.

Colombo, 11th May 1882.

DEAR SIR,—Some not well acquainted with the subject might be misled by the letter of your correspondent, P. D. Millie. It is true that a few parcels of finest coffees fetched the prices he names, about February last, and at the time middling coffees were at their lowest point; but it must not be forgotten that these high rates were only paid because coffees of such quality have been so very rare amongst our shipments this year, and that the number of marks which have fetched those top prices could be counted on one's fingers. Coffees which were but slightly inferior, indeed so little so that planters would probably not distinguish any difference, have been sold at 15s to 20s per cwt. below these rates, and now even the marks named by your correspondent would probably fetch less by 10s per cwt. than in February last, owing partly to the influx of fine East Indians, against which it can scarcely be said that Ceylon is holding its own.

If estates are not kept up as formerly, not only shall we be deficient in quality, but Ceylon will rapidly lose its name quality also.—Yours truly,

VERY PALE.

THE BROUGHTON ESTATE CINCHONAS.

Badulla, 12th May 1882.

SIR,—My attention has been drawn to your articles in the *Observer* of 5th and 6th inst. on the analysis of "hybrid bark" obtained from some cinchona trees grown on Broughton estate, Haputale, particularly alluding to that portion of the estate that was once my property, and soliciting "enlightenment" from me on the now puzzling question of cinchona "hybrids," or at least information about the "*offspring*" of those (succirubra and officinalis) parent trees planted by me on Mahaputiya estate in the year 1865. I obtained the original plants from the Hakgala garden when the late Mr. McNicoll was Superintendent of the Government Cinchona Plantation. As far as I can recollect there were only the two varieties, viz. *succi-*

rubra and *officinalis*, available for distribution from the gardens at the time, other kinds having since sprung into existence, and now their name is *legion*. I applied first for 2,000 plants to the late Director of the Peradeniya Botanical Gardens, and, on signing a document promising to attend to their proper cultivation, I was granted an order to receive 2,000 plants (1,000 suc. and 1,000 off.)—I was then manager of Monerakande and other estates in Haputale. I got the plants down to Monerakande intending to plant them there, but, when I was doing so, Mr. C. Tottenham, one of the then proprietors of Monerakande, visited the estate, saw what I was doing, appeared to be annoyed at such a waste of labour, and ordered me to desist from ornamental cultivation, pull up and throw away what I had already planted, and on no account to go in for any more æsthetics! I had already planted out some 500 plants along the road sides, but so little were they cared for or looked after, that only a few trees were on the estate a few years ago—the balance of the plants (some 1,500) I sent over to Mahapitiya and had them planted out *alternately* along the road sides, round the boundaries of a 60 acre clearing, and on both sides of the ravines, after I lost the estate in 1867; how the plants fared I cannot tell, but I heard say that some subsequent superintendent cut down and destroyed most of the trees for the reason of their overshading the coffee, especially those in the ravines. Those old trees that Mr. H. H. Capper found on a portion of Broughton estate were the remnants of the cinchonas I planted in 1865. We only knew of two varieties then, succirubra and officinalis, but since then plants have grown from seeds set down under the old trees of so many different shaped leaves that they had commenced to puzzle even the most scientific botanists, and it is the fashion now to give new-fangled names to the plants by the shape, size, or colour of the leaves: they are so numerous already, there is no saying where the nomenclature will end. I leave it to such luminaries as the *Observer*, Forbes Laurie, and William Smith, and other minor satellites, to fight out the battle of hybridization; in my humble opinion these freaks of nature, sports, crosses, or whatever you may call them, will go on *ad infinitum*, till we have as many kinds of cinchonas growing, as there are races of mankind* on the face of the earth. Apologizing for the length of this letter, I remain, sir, yours faithfully, JNO. ATWELL

P.S.—I may mention here that in 1863 I visited the Hakgala gardens for the first time in company with the late Mr. G. B. Carson, then proprietor of Gonamotava estate, and could only purchase *five* plants grown under glass shades in neat little pots. I had to pay 5*s.* 6*d.* for each plant: I could not get more. These plants I planted on Gonamotava estate in 1863, and not long ago two or three of *these first plants*, introduced by me into the Haputale district, were to be seen near the site of the old bungalow on Gonamotava estate.

SEVERE PUNISHMENT FOR FOOD ADULTERATION RECOMMENDED.

12th May 1882.

SIR,—I enclose the following extracts, say one from a leading London daily (probably the *Daily Telegraph* but I cannot say for certain) and one from *Truth* of 13th April last.

In reference to the extracts above referred to, I would beg to suggest that, considering the great power possessed at the present day in the councils of our state by publican, and grocers (perhaps I ought to place the latter first), I consider it a blight upon our great nation that the statesmen representing it (be they Conservatives or Liberals they are equally guilty) should so debase their high functions as to "flirt" (that is Mr. A. Mackenzie's term, as lately applied in indignant terms, when twitting his brother-planters with not backing him up in blackballing in season and out of season a perhaps foolishly weak Haputale Magistrate) with the representative multitude of these all powerful trades whenever they (the said so-called statesmen!) have to legislate *for the good of the people*!

I would suggest that every importer, manufacturer or tradesman who was found guilty by our courts of law of adulterating the *staple food or drink* of the people (be the latter alcoholic or *non*-alcoholic) should, *in addition to fines*, be punishable say for a third offence with the loss of his vote at the general election, the fourth for *two* elections—the fifth with *three* elections, and sixth *with a total disability to vote on any election whatever*, and also with imprisonment at hard labour according to the heinousness of his offence.—I am yours truly, A FRIEND OF THE PEOPLE.

*The off-hand way in which this writer disposes of questions on which the greatest men of science speak hesitatingly is quite refreshing.—ED.

INFORMATION ABOUT CARDAMOM CULTIVATION DESIDERATED

May 13th, 1882.

DEAR SIR,—As cardamoms are being grown, and will, I believe, be extensively cultivated later on in the hill districts, as well as in the lowcountry, it is desirable that planters experienced in this new product should give the results they have obtained in the cultivation of it.

Information on the subject is much needed. Could Mr. Holloway, or any other of your able correspondents, be induced to give it us, in the form of a pamphlet, describing in detail the treatment of the cardamom from the making of nurseries to the final shipping in Colombo? A book of this kind joined to "All About Cardamoms," published by you, would be a boon to planters intending to go in for this product.

I cannot say yet with certainty, but I believe it would pay well upcountry, judging from its growth and power of blossoming at 4,000 feet elevation in

YAKDESSA.

[On an estate in Ambagamuwa, the plant has failed to give a satisfactory return of fruit at a far lower level than 4,000 feet.—ED.]

QUESTION ABOUT INDIA RUBBER.

DEAR SIR,—Being interested in the cultivation of rubber, I shall be exceedingly obliged, if you, or any of your correspondents, will inform me how long the Mozambique pink rubber (*Landolphia Kirkii*) takes to come to maturity. If, as a correspondent in the *Observer*, of the 29th March, hints, it is closely allied to the Para rubber, probably it will take nearly as long to come to maturity, which is, I believe, about ten years. In that case, will it not pay planters much better to stick to Ceará rubber, from which there is a good return two years after placing the seed in the ground. I have just been tapping a Ceará tree only six months old from which I collected a small ball of rubber? The tree is very hardy and seems to stand wind remarkably well.—Yours faithfully, CEARA RUBBER.

CINCHONA BARKING: FAILURE OF A COMPLICATED MACHINE AND SUCCESS OF A SIMPLE DEVICE.

Lindula, 15th May 1882.

DEAR SIR,—In hard times like these I would not willingly injure any man's prospects of making money, especially when the means are so honest and credit-

able as the fruits of one's own inventive genius. But on the other hand I think it is far more important that the many should not *lose* money by investing in what is a dead loss so far as my own experience goes. I refer to De Caen's peeling machine, which I regret to say does not answer to its description in one single point. It is said to be easily carried to any part of the estate by *two* coolies: I find that *three* can carry it in and out of my teahouse, but *four* are required to carry it any distance beyond 100 yards (*vide* Messrs. Walker & Greig's post-card enclosed). It will not peel any twigs smaller than the little finger, except in bundles, and the single twigs it *mashes* most unmercifully, the result being very unsightly and damaged bark; and it as often squeezes the bark into the wood as loosens it. And most important of all, with personal superintendence I found that with two *men* at the wheel (boys will not do), two boys feeding, and one boy supplying twigs, I could not get from women barking more than 5 or 10 lb. apiece: say 50 lb. from 10 people, instead of 400 lb. from 5. The above is only my personal experience, and I shall therefore be only too glad for the sake of the inventor as well as the planters at large if it is proved that it is *I* who am at fault and not the machine.

To make up for my disappointment, just as I had decided to take to knife-peeling again (by which I can always get from 10 to 20 lb. of smallest twig bark) my assistant heard of a *dodge* (discovered, it is believed, by Mr. Sandys Thomas of Lindula) whereby 20 to 40 lb. of bark from any twig above a hair's breadth can be got easily; and beautiful bark too. De Caen's machine costs R60: ten of *these* machine can be made for 60 cents! The process is simply this:—Tie two rounded sticks or bamboos about 3 feet long together at one end only; tie the tied end to a firm post or gum-tree, and your machine is ready. Put your twig between the two sticks, squeze them together with your left hand while you pull the twig through with your right, and the bark almost always falls off of itself in two fine unbruised ribbands. If you wish *to imagine* what the machine is like, close all fingers except the first and middle of your left hand: then draw your pen through the latter (only take care to have the inky end towards you!). This contrivance takes the bark off the very smallest twig, which I claim was *the* desideratum, and which De Caen's machine will not do. I have seen neither Rae's nor McInnes-Mackenzie's invention, so write without prejudice and only from a sense of duty. You can substitue my name for my *nom-de-plume* if you think fit. KÁROLY FÜRDÖ

THE INDIARUBBER TREES AT THE COLOMBO ACADEMY (NOW THE ROYAL COLLEGE).

DEAR SIR,—I have continued to read with great interest the various accounts of india-rubber plants in your columns; but I have been watching for some time in vain for a description according to the character of the "indiarubber trees" of old Academy boys. As far as I remember the *blossom* of the tree had a sheath very like that of a breadfruit. Every part of the tree on the slightest wound exuded a freely flowing milk, which rapidly dried. This was largely availed of by us to make balls of, particularly the cores of cricket balls. The process was to rub rapidly between the palms of the hands, when the ball formed, leaving a rough surface, but being a rough and ready ball all the same. With the friction of the hands the drying process was very fast. Was not this therefore a *Landolphia*? * There was a complete row of these trees alongside the broad verandah, where taught at various times Messrs. J. R Blake (ever-to-be-honored name, though I was not his pupil), "Tom Smith," W. B. Sproule (brother of the late Rector of Bath), S. Lister (from England) and others of less note. The trees were, perhaps, young when I knew them (a quarter of a century ago) but they were sturdy and flourishing and gave *no end of milk* to the little ones of the school!—Yours truly,

TWO STAR.

[My signature has no reference to the bark of oak trees.]

* It is the *Ficus elastica*, from which some India-rubber is gathered in Java.

THE PURE CALISAYA LEDGERIANA SEED (2 800 grammes) offered for sale by Mr. Symons today (May 5th) realized from R6 to R10 per ounce.

BRAZIL COFFEE CROPS AND UNITED STATES POPULATION AND CONSUMPTION.—If, as Mr. Blacklaw seems to think, the Brazil crops are not likely to increase, the question of increased population in the United States—where coffee is consumed at the rate of 8 lb. for head—becomes important. This year and each succeeding year, for sometime to come, it is expected that one million per annum of immigrants will land in the ports of the Union. Then there is the natural increase. The prospect certainly is that, ere long, the United States will consume all the coffee Brazil can supply.

NOW THAT NORTH BORNEO has become a seat of European enterprize, it may be worth while to consider how the opening out of that new country may affect us in India. We have not at hand correct details as to the temperature of the island, but, lying so near the equator as it does, the climate must be hot, while the proximity of the sea will temper the tropical heat of the sun. We assume, therefore, that, for the growth of tea, the climate will be all that can be desired. The Southern States of America were found suitable for the same industry as far as mere climate was concerned, but the want of a sufficient rainfall made the industry an impossibility, because, although the plant grew and yielded leaf, it would not yield in sufficient quantity to make the industry a financial success. Borneo, however, is even more suitable than many parts of India in this respect, as will be seen from the following table, which we extract from the *Sarawak Gazette*, giving the rainfall for 1880 and 1881:—

1880.		1881.	
January ...	17·14	January ...	69·25
February ...	14·59	February ...	7·31
March ...	15·33	March ...	24·46
April ...	13·03	April ...	7·62
May ...	6·83	May ...	7·61
June ...	6·66	June ...	4·80
July ...	7·45	July ...	3·67
August ...	11·32	August ...	7·36
September ...	22·55	September ...	4·02
October ...	15·26	October ...	18·81
November ...	17·19	November ...	23·13
December ...	7·28	December ...	7·99
Total ...	154·28	Total ...	186·03

We see visions of a twelve months' season here. Nature will doubtless provide a season of rest for the bushes, and a glance at the above table would seem to indicate the months of May, June, and July as the period when the tea-plants might be pruned, and allowed to rest for recuperative purposes.* If, however, the cultivation of tea be attempted on those elysian shores, no variety but the purest hybrid or Assam indigenous should ever be allowed on the island.—*Friend of India and Statesman.*

* As in Ceylon.—EDS.

CINCHONA.—While some planters are advertizing for old newspapers wherewith to clothe their shaved cinchona trees, the "old rag" being carefully preserved for this purposes in many bungalows, in other cases the leaves of the cinchona itself tied on with mana grass are found to do very fairly for a temporary clothing. By many the shaving of trees from 3 years old and upwards is considered to be preventative of canker and decay at the roots. Blocks of wood are used as substantial substitutes for the bottles filled with sand in loosing bark from twigs and branches preparatory to stripping. By the way that was an interesting letter from a "Cinnamon Planter" the other day in which he described the preparation of "chips," the cost of scraping which is 3c. per lb. (while the value is from 7c. to 8c). The margin of profit is here certainly very close, and like the young twigs of inferior cinchona it will scarcely pay to harvest them.—*Planting Cor.*

WELL IRRIGATION.—Mr. E. B. Thomas, a retired Madras Civilian, has addressed the Government of India on a subject which is now receiving great attention, irrigation of land by means of wells. In the Jaffna Peninsula, well irrigation has been carried to great perfection, but the system is surely applicable to many other parts of the colony where irrigation tanks would be failures. From Mr. Thomas's paper we quote as follows:—In India, under the influence of a tropical sun, waters will produce grain in almost pure sand, and no one, therefore, will probably question the oft-repeated assertion "that irrigation (wherever practicable) should be extended to the utmost." It surely has been so to a very large extent. In three provinces in which I served (in Tinnevelly seven years; in Coimbatore eighteen years; in Trichinopoly three), I know that under the care of intelligent engineer officers every drop of available water for irrigation *was* utilized in cut channels of 70 and 80 miles long. No waste water reached the sea except at high floods. All river water was diverted into water-courses or into tanks, the rice crops being often finally saved by *wells*, when the channels began to fail. But much lies behind the one word "*practicable.*" Irrigation is only practicable in level tracts bordering on perennial and unfailing rivers, chiefly from the south-west monsoon. To cover India with a network of channels and series of tanks, all certain to dry up on first failure of the monsoons, would only be a costly delusion. There are many provinces above the level of practicable irrigation; others with only small *temporary* rivers, which are torrents in the rains, but dry beds at other times. Again, there are soils *unfit* for irrigation, where water, if supplied, either disappears as through a sponge, or where the permeating water brings to the surface salts or other latent ingredients fatal to crops (some such are found, I believe, on parts of the great Ganges canal). One failure of a monsoon dries up all tanks and channels not fed by a *perennial* river; but a *well* will stand one, or even two, such failures, and still irrigate a portion of the land immediately round it, and save grain enough for the ryot's family, while the *straw* saves his *cattle*, with drinking water for both. Moreover, the water raised and used for the fields near the *well* percolates partly *again* into the wells, and is raised a second time, for renewed use. Not so with a tank or channel; the water flows once over, and *off*, the field, and is lost. The well, too, is the ryot's own property, and adds (ten-fold) to the *saleable value* of his land, and is thus a safeguard and an advantage both to the ryot and the State; for, if the ryot prospers, the State benefits, and is sure of its rent. "Mountain reservoirs" are specious, but *practically* of little use: as too distant, the water is absorbed and wasted ere it reach the plain: canals, where practicable, and branch rail roads, where required, are self-evident necessities.

THE TITHE OF A COFFEE PULPER.—The *Natal Mercury*, in an article on Madagascar, gives curious details of the galling interference of the native custom officers, amongst which we find the following:—They one day wanted to get for the Government the ten per cent. duty for a machine for disengaging the grain of coffee from the pulp, and were actually on the point o cutting off at one end the tenth part in length of the machine, and so totally destroying it. This is of course very ridiculous, but it is illustrative.

PTEROCARPUS SANTALINUS OR RED SANDERS SEED.—Noticing a new advertizement in today's (May 12th) issue for the sale of theseed of this valuable tree, we quote what Balfour, in his "Timber Trees of Southern India," says:—"Its wood is sold by weight as a dye wood and forms a regular article of export. The natives convert it into posts for houses and it is preferred to any other timber. It is heavy, extremely hard with a fine grain, much used as a dye-wood by color manufacturers and also in turnery taking a beautiful polish. It yields its coloring matter to alcohol and ether but not to water."

A GOOD STORY comes from Mincing Lane. A merchant lately gave a broker a sample to value for him, and this was done, and reported as being worth 5d a lb. It was eventually put up to public auction, and, on the merits of the sample, realized 6d a lb. When the merchant next met the broker, he upbraided him for having undervalued the tea. The broker admitted this; but added that the Customs had valued it at still less, for it had been ordered to be burned—the fact being that the two ends of the boxes from which the sample would be taken had a layer of inferior tea, while the inside was filled with rubbish. This, luckily, was discovered before the "tea" got into "consumption."—*London correspondent of "Aberdeen Journal."*

A CONCLUSION ABOUT CROPS.—A correspondent writes:—"Dear Sir,—In the letter headed 'Necessity for Retrenchment,' in your issue of 10th inst., we find the words:—'The crops of the last ten years have been governed by a visitation which no human wisdom could have foreseen.' The impossibility of the foresight may be doubted, because coffee leaf-disease seems but a parallel to the potato, hop, and vine diseases. In each case the diverse natural vegetation of large tracts of land has been destroyed to make room for the cultivation of a single plant, and the various diseases must surely be regarded as the efforts of nature to reassert itself. This is my CONCLUSION." Our correspondent's conclusion has suggested itself to many minds, but it is liable to some qualification, for the vegetation which nature herself places in a certain habitat is liable to disease and death. In many parts of Australia, notably in Gipps Land, we passed through square miles of what had been verdant forest, but which had been converted by a small moth, that ate up every leaf, even of the pungent *Eucalypti*, into an expanse of still grand but gaunt and weird-looking skeletons. Our jungle trees here are not exempt from visitations of the kind. The guava is specially the victim of the coccus which at one time threatened to kill our coffee. It did not succeed, and we trust the fungus will be equally unsuccessful in the attempt at extirpation. It is only recently that the rules of true science have been applied to the laws of nature generally and of plant life specially, and we have still much to learn. We suppose that most of us, if we had the ordering of matters, would dispense with destructive and noxious insects and vegetable growths. Why venomous snakes should have been created or "developed" is to most of us as much a mystery as the existence of evil and an evil one. We have to face the facts nevertheless.

ILLUMINATION.—A real panic has at last broken out among the gas companies. A member of the Brazilian colony in Paris, Sr. Olympio Barcellos, has discovered a process of burning air for illuminating purposes, and it will cost only 50 centimes for a whole year. The process is still a secret within the brain of the inventor.—*Rio News.*

THE PROPERTIES OF TEA and the names of the prepared leaf are thus noticed in a review by the *Grocer* of the Tea Cyclopædia :—After touching upon some of the chief points in reference to the discovery, cultivation, and consumption of the article, it may be interesting to offer a few remarks upon the "properties of tea," which, it must be owned, are rather various, if not conflicting. According to the Cyclopædia, we say that a green tea has a fine flavour, also that a congou has a fine flavour, but they are totally unlike. The volatile oil it contains gives to tea its flavour. The effect of this oil is to produce wakefulness; but, on the other hand, the best authorities declare that "theine," another property in tea, does *not* create sleeplessness, being of a nature to soothe and compose. Theine also supplies to the human system what it loses by fatigue. This property in coffee is called caffeine, and the drinking of it is attended with similar results; but at the same time it is well known that "green tea will produce effects on persons that black teas will not," and that there is a greater fermentation in black tea than in green. Tannin, which is a powerful astringent, is another ingredient in tea; when chewed it "puckers up the mouth," but it is thought by some that it aids digestion. "Tasting tea upon an empty stomach is injurious, producing a sense of weakness as if one had fasted a long while;" and "tea experts," who are at it all day, "are made exceedingly nervous." Some assert that there is nourishment in tea; others say that there is none, and that tea consumes food; whilst the book we quote from informs us that tea, like liquors and drugs, when taken moderately, will have one effect, but if consumed largely it will produce just the opposite. With regard to the names of different sorts of teas and their meanings, we may state that "Pekoe" is a term from the Chinese "Pai-hao," white down or hair, because made from young spring leaf-buds, while they are still covered with down. "Souchong" is from "Seao chung," which means little sprouts. "Congou" is a corruption of "Kung-fou" or labour; and "Hyson," or He Chun, signifies fair spring; while the meaning of "Young Hyson" (Yu-chien) is, before the rains. The instructions for "making tea" are likewise very useful, and cannot be too widely known; and retail grocers might render a service to their consumers by giving them seasonable directions. In the first place, "tea should not be boiled, as the volatile oil will escape with the steam, and a much larger proportion of the tannic acid is extracted, leaving the infusion bitter." The best way to make tea is to have an earthenware teapot, which should be quite hot when the dry tea is put into it. A few minutes after, pour in the boiling water upon the tea, which, after "drawing" from seven to ten minutes, "is at the best point for drinking." A sufficient quantity that is wanted for use directly should be made at the first drawing. The habit of filling the tea-pot a second or third time is not right, because the theine, which is quickly soluble in scalding water, will have escaped, so that those drinkers who are supplied from the second drawing will lose the most beneficial part of the tea, and will have instead "a decoction composed chiefly of tannin." Churned tea, properly prepared with milk, is a beverage highly prized in Cashmere in entertaining visitors: and we are told that "the ladies there no doubt vent their grievance to sympathetic ears, discuss their bonnets and their babies, and talk scandal, over this cup in much the same way as their English sisters do over 'Five o'clock tea."

COCOA.—There has been another sale of Ceylon cocoa, this week, but it won't bear comparison in any way with Mr. Tytler's sale reported in my last, the bulk of which fetched 116s. There were only 9 bags from the Woodslee estate, 7 of which realized 71s, and 2 only 20s 6d. What had happened to it I don't know, but it was almost black, and these were considered by experts very fair prices.—*Cor.* "Ceylon Times."

ALAVANGAS AND BIG MACHINES FOR CINCHONA BARKING.—Haputale, 24th May 1882.—We are now having mild and calm weather, after a regular burst of wind which blew the cinchonas about a bit, especially big suckers growing from stools. The latest method of twig-barking is to drive two alavangas into the ground, place the twig between the alavangas, seize the alavangas with the left hand at their upper ends, and with the right hand draw the twig through. I have heard this simple mode does a wonderful bit of work, comparing more than favorably with the twig machines at present invented.

THE NEW COFFEE EXCHANGE.—New York, March 15th.—The newly organized coffee exchange is now in operation. Señor Salvador de Medouça, Brazilian Consul here and other prominent citizens, were present at the opening ceremonies. The market prices in Rio are to be cabled over and posted up daily, and there are two daily calls, one at eleven a.m. and the other at one p.m. Mr. F. N. Saunders, the manager, told your correspondent that, for a while, transactions would be confined to "Rio strictly good ordinary," but that he hoped soon to see Java, Maracaibo, and Jamaica coffees added to the list. The calls are for future options in the coffees for each of the 12 months in the year in regular order. The first sale made on the exchange was by Scott & Co. of 250 bags to Small & Co., at 8¼ cents.—*Gail's News Letter.*

WHEAT is subject to a malady known as rust or smut; it attacks the grain in the ear, transforming it into a shapeless mass, of a morbid tissue, and destitute of all nutritive qualities. Mr. Davaine traces the cause of the malady to an eel-shaped worm, which picks the tissues of the flower, and hence the development of the grain becomes abnormal. M. Braun admits the existence of the worm, but locates its action in the pistil of the flower, thus arresting development. M. Prediéu last summer—having sowed wheat so diseased—when the plant came into flower, saw by the microscope the worms pricking the stamina off the flower at the point of the ovary; the tissue become distorted into a tube which formed the kernel of the blasted grain. Preserved in the grain the worm regenerates itself in the soil where the diseased grain is sown, and can retain its vitality for 25 years.—*Gail's News Letter.*

A NEW TEST FOR DAMAGED SEEDS.—In the purchase of seeds, so common at this season, one is apt to be deceived. A correspondent of the *Journal d' Agriculture Pratique* recommends a test which he has used for many years with complete success. It is that of *fire*. Take at random a number of seeds from the bag, say eight. Put some live coals on a shovel, and deposit each of the seeds successively on it. Blow the coal, and watch how the seed behaves. If the combustion is slow, merely giving off some smoke, you may conclude that the seed had a damaged germ: if, on the other hand, the seed leaps and turns about on the coal, producing a dry sound (tac), proportional to the size, it may be inferred to have good germinative qualities. In this way the proportion of good and bad seeds may be ascertained. As for the larger seeds, such as acorns and chestnuts, it is sufficient to throw them into a fire, and keep them in view. If the quality is good, this will be indicated ere long by detonation of the seed. —*Public Opinion.*

MR. GLADSTONE DOING A MEASURE OF JUSTICE TO COFFEE.

We are able this day to quote, from the Price Current of Messrs. H. Pasteur & Co., the text of the resolutions forbidding the adulteration of coffee with any substance except chicory, which the Prime Minister, as Chancellor of the Exchequer, announced in his Budget speech as decided on, and we quote that portion of the Financial Exposition which referred to the revenue derived from alcoholic and non-alcoholic drinks. The case of coffee in itself, but especially as compared with tea,—the one left open to adulteration which indeed was invited by a series of Treasury Minutes ; while the other was stringently protected—could not but force itself on Mr. Gladstone's attention. But we cannot help thinking that the action of the right hon. gentleman was largely influenced by the representations made to his government by persons interested in the coffee industry and trade, culminating in the Memorial of Feb. 6th, signed most numerously and influentially. The gratitude of the coffee planters of Ceylon as well as that of coffee planters everywhere is due to Mr. Thomas Dickson for his zealous efforts, and very especially to Mr. H. Pasteur for the convincing figures he prepared and argued from. He compiled a statement shewing the consumption of coffee in Britain in every year from 1842 to 1881, and shewed that

Whilst in 1854, with a duty of 3d per lb., 37,472,000 lb. were consumed in this country, in 1871, with the same duty and with a population which had increased by some 5 or 6 millions, the consumption fell to 31,000,000 lb., whilst in 1881, with a duty reduced by one-half, *i.e.* to 14s. per cwt., and a population greater than in 1871 by 3,000,000, the consumption was was not more than 31,943,000 lb.

He went on to affirm that

This decrease in the use of one of the best and most wholesome of beverages, the consumption of which, in every other country of Europe and in the United States has increased enormously and goes on increasing year by year, is the direct result of a system of fraud and adulteration, which has been carried on, and is growing steadily, as it were, under the tender care and solicitude of the British Government, who from time to time revise the regulations relating to the sale of coffee and the various cheap mixtures with which it is adulterated, so that the ingenious importer or manufacturer of ground and roasted acorns, or carrots, or any other nasty compounds, may have full scope for the exercise of his industry. (I do not name chicory, which seems to have become an almost too respectable substitute, judging by the fact that even the consumption of chicory has been less in 1881 than in 1880.) I do not think any one will call the above statement either exaggerated or highly colored, who will take the trouble to glance at the Treasury orders, issued from time to time on the subject, and which are enumerated in the last column of the tabular statement on the first page.

He, naturally enough (his justification being their own extraordinary proceedings) stated that it looked as if the Treasury and Excise had taken pains to find means to check and prevent the sale of coffee for consumption in Britain, by encouraging not merely chicory growers but preparers of date powder and all possible descriptions of trash which were allowed to be sold as coffee. Mr. Pasteur very naturally and fairly asked

Is there any good reason why the same regulations, which are considered fair and necessary to protect the revenue from the tea duty, should not be applicable also to coffee? Why should tea be protected by legislation against adulteration and not coffee also? Is it too late to bring the subject again under the consideration of Government? Surely the coffee-growing British colonies or possessions are as deeply interested in this question as the traders in this country; their representatives and the Planters' Associations, should not rest until they have succeeded in obtaining common justice and fair play for one of their most valuable and important productions.

This was in January. In February, Mr. Pasteur followed up his first attack by another specially directed against the astounding Treasury order which positively invited the importation of all possible substitutes for and adulterants of coffee. Mr. Pasteur wrote :—

To state that coffee is one of the best and most useful of beverages, and that its use ought to be encouraged on economical as well as sanitary and moral grounds, is to repeat a truism. It is esteemed as such, and its use encouraged in all countries, save one, and its consumption is steadily increasing everywhere except in Great Britain. In America the consumption is at the rate of over 8 lb. per head per annum; in Germany, with a duty of 21s per cwt., it is 5 lb. per head; in France, with a duty of 60s per cwt., it is 4 lb. per head. In England it was nearly 2 lb. per head in 1847 with a duty of 36s per cwt., but now, with a duty of 14s per cwt., it is less than 1 lb. per head, and yet we import annually some 70,000 tons of coffee or five times the quantity consumed. The reason of the growing disfavour for the article is *solely* and *entirely* owing to the wholesale system of adulteration which flourishes under the regulations permitting the sale of, and since the 20th January, the importation of *any kind* of stuff mixed in *any proportion* with coffee. That the regulations hitherto in force did not protect the revenue is amply proved by facts; the duty on coffee yielded £216,800 in 1879, £203,500 in 1880, and £199,000 in 1881; and the aggregate received in 1881 for duty on coffee and chicory is actually less by some £4,000 than the amount received in 1880. Do the lords of the Treasury believe that by extending the duty to other vegetable substances imported mixed with coffee and chicory they will protect the revenue under that head? They might know, and they ought to know, that the result will be exactly the reverse; the public will leave off more and more drinking the wretched stuff which is sold to them under the name of it, or coupled with the name of, coffee, and they will take to beer and spirits instead.

But, setting aside the question of revenue, another aspect of the case appears to have entirely escaped the attention of their lordships. Is it just, or right, or fair, that the name of coffee should be used as a sort of decoy? and that, by tacking to it some other name or epithet such as *chicory* or *French*, *Jersey date*, or *Fig* coffee, any kind of worthless or nasty substances should be allowed to be mixed with it, for the sole object of getting a profit which could not be got, if those articles were sold under their proper name. The public are powerless to protect themselves against those pracites, although we are gravely told that the persons who infringe the regulations of the *Sale of Food and Drugs Act* render themselves liable to prosecution; the endless formalities required, and the expenses of analysis, &c., are such that the offending person is almost sure of immunity, or at the most, if prosecuted by the Excise officers, of a fine so slight as to be a matter of perfect indifference to him.

In fact the foreigner is told: *we allow you to mix any quntity you like of saw-dust, of acorns or roast carrots or cabbage stalks with coffee or chicory, and you may import them hear our customs officers will charge you a duty of 2d per lb.; but, as you will be infringing the Adulteration Acts, our Board of Inland Revenue officers may then proceed against you or your agents, and levy fines for such infringment.*

The Treasury allow the importation of stuff which they know to be spurious and of no value, and unsaleable here or anywhere else, except under a fictitious name. I repeat is it right or just, or moral? Why countenance or allow the importation of those mixtures? What are the interests which appear to Government so worthy of being encouraged and protected at the expense of the British public and of

all those engaged in an important article of trade? It cannot be for the sake of placing within reach of the million a wholesome and pure beverage at a reasonable price; for those wretched mixtures are sold at 1s per lb., whilst good pure coffee can be bought in the shops, roasted and ground, for 10d or 11d per lb.

Then came the Memorial, so largely and influentially signed, in which Mr. Pasteur's arguments were recapitulated and which concluded with the expression of the belief that

The consumption, if it had not been checked by unfair legislation, would probably exceed now 60,000,000 lb.

The history of the trade in tea, an article which was carefully protected from mixture even with exhausted tea leaves, largely justifies this conclusion, as becomes obvious when the figures are scanned and the results weighed of comparative statements of the coffee and tea trades of the United Kingdom for three decennial periods, 1852-1881.

In the first period a population of 28 millions (average) consumed 35½ million lb. of coffee, or at the rate of 1·4 lb. per head. In the second period, 30½ millions consumed only 31,385,000 lb. or 1·0½ lb. per head; while, in the ten years ended 1881, a population increased to 33,309,000 used only 32,715,000 lb., or 0·15⅝ lb. per head.

Meantime, tea, the adulteration of which was strictly forbidden under very heavy penalties, advanced rapidly as the figures will shew. In the ten years 1852 to 1861, an average population of 28 millions used 67,558,000 lb. of tea, or 2·6 lb. per head. In the next ten years a population of 30,284,000 consumed 102,369,000 lb. of tea, or 3·6 lb. per head an advance of 1 lb. per head. In the third decennia period, that which closed with 1881, 33,309,000 average population used 148 million pounds of tea, or 4·7 lb. per head, again an advance of a fraction over 1 lb. per head.

But, instead of the periods and averages, let us take one of the earlier years and the closing year of the thirty year period.

In 1854, then, 27,450,000 population used 37,350,000 lb. coffee, or 1·6 lb. per head. The course was then downwards, until in 1881, with a population increased to 35 millions, the consumption of coffee was only 31,243,000 lb., or 0·15 lb. per head.

With tea the reverse process took place, for, while in 1852, a population of 27,450,000, used 54,713,000 lb. of tea, or 2 lb. per head, in 1881, a population of 35 millions consumed 160,225,000 lb., or 4·9 per head.

The detailed statements are worthy of deep attention, and we repeat that we cannot doubt Mr. Gladstone's attention was attracted to and his action largely influenced by the figures and arguments to which we have been referring. We extract that portion of the Budget speech which commences with the recognition of diminished revenue from beer, spirits and wines —the alcoholic or "drink revenue," as Mr. Gladstone called it. Except in the strange fact that in wines there is more than a proportionate decrease, when compared with beer and spirits, the diminution is matter for gratitude. Mr. Gladstone, however, seems to think that the money saved on alcoholic drink has not gone in tea or coffee, but has been absolutely saved. It may be so, and, as far as coffee is concerned, who can wonder if neither consumption nor revenue increased in the face of hostile legislation by Government. At length date coffee and all substitutes, except chicory, are expressly banned, and, if only a statement of the proportions of coffee and chicory were enforced by law, coffee would have nothing to fear. But coffee, like tea, ought, in Mr. Gladstone's own words, to be placed in a similar position with tea, so as to be "able to encounter alcoholic drink in a fair field and throw it in fair fight." We cannot doubt that the mode in which coffee has been handicapped and discredited in the contest has given alcohol largely the advantage in the past. In the future we have now good hopes that coffee will march *pari passu* with tea and cacao in superseding alcoholic beverages in favour of those which, while they cheer, do not inebriate.

JUSTICE TO COFFEE.

The following is the extract from Mr. Gladstone's speech :—

Notwithstanding the increase of population, our receipt from beer duty is less by £90,000 than the average receipt from the old malt duty in the years between 1873 and 1879, I represent a state of facts in which there is some collapse somewhere. Is that collapse due to any alteration in the habits and practices of the people? (Hear, hear.) The Board of Inland Revenue officers, whom I consider to be good authorities on the subject, do not exclude that supposition, but they do not look to it as the main cause. They say that, although employment in the country is general, yet wages have not yet reached the full average level, and undoubtedly have not reached anything like the level which they reached in the years of prosperity between 1873 and 1879. They also observe, and I have no doubt there is something in this, that last year in the cider counties there was a very great abundance of fruit, and a very large consumption of cider. Then comes another fact—the great increase of coffee-houses and clubs, which lead to the supposition of more temperate habits, and which are a proof of this deficiency in the revenue. (Cheers.) I think the house will deem it quite worth their while to spend a few minutes in endeavouring to get as accurate information as we can upon this subject and to put ourselves in a position to estimate fairly the influences which are at work. We have a group of simultaneous facts, which, taken together, are very curious, and do not all run quite in the same direction. In the first place, there is a very decided decline of the drink revenues proper. I hope my hon. friend the member for Carlisle approves of the term I use. (Hear, hear.) It is something disparaging, and that I am sure will be agreeable to his feelings. (Laughter.) I have got here a statement of the revenue derived from spirits, wine, malt, and beer, with the attendant licence duties and so forth at three separate periods. I have taken 1867-68, which was before the great rise of prices; 1874-75, when that rise of prices and wages was still on the whole in operation; and 1881-82, the last financial year. The entire revenue from these sources in 1867-68 was £23,001,000. In 1874-75 the revenue had sprung to £31,029,000. In 1881-82 it had gone back to £28,444,000. the most curious circumstance in this is that the wine revenue advanced from the time of the important change in the duties in 1860 in a very steady manner for a great number of years, and in 1874-5 it was £1,719,000; so that with our duties on wine varying between 1s and 2s 6d a gallon we were deriving about the same revenue as we had been accustomed

to receive with a uniform duty of 5s 10d a gallon. But ever since that time the duty upon wine has been receding in a much greater proportion than other revenues from alcoholic liquors. The total of these revenues fell from £31,029,000 to about £28,500,000, or roundly about one-eighth; but the duty on wine fell from £1,719,000, to £1,366,000, or by more than one-fifth. However, there is the fact that there is a great diminution, notwithstanding the large increase of population between 1867 and 1881—an increase in the population which could not be less than 4,000,000 people. The gross revenue from these sources, which had risen to £31,029,000 in 1874, fell by more than £2,500,000 with an increase of population between 1874-75 and 1881-82 of considerably over 2,000,000 people. It is also rather curious to take the proportion in which we have been dependent on this source of the revenue of the country, and, in order to show that I have compared the liquor taxation of the country, as I would call it, with the non-liquor taxation—meaning by the non-liquor taxation all the tax revenue of the country except the income-tax, which I do not include on account of its frequent variation—but I put on one side the taxation derived from alcoholic liquors and on the other side the taxes derived from all other sources except the income-tax. Taking the percentages on that basis, they stand as follow:—In the six years from 1859 to 1865 we levied 37½ per cent on our taxation from alcoholic liquors and 62 from non-alcoholic liquors. In three years from 1866 to 1868 we levied 42 per cent from alcoholic liquors and 57½ per cent from all other sources. In five years, from 1869 to 1873, we levied 46½ per cent from alcoholic liquors and 53 per cent from all other sources. In 1874-5 to 1879-80 we levied 51 per cent. of our whole taxes, except income-tax, from alcoholic liquors, and 49 per cent. from all other sources. That is a very curious state of facts. Since that came the reaction. I have carried you thus far down to the year 1879-80, when we may say that one-half of our taxes came from alcoholic drinks and the other half from other sources. But during the last three years a reaction had begun. Alcohol had gone down to 47½ per cent. and non-alcohol had risen to 53 per cent. But, then, you may say: "If this diminution of consumption is going on, and you have shown it to be so considerable, and if a main cause of this diminution is the foundation of those valuable and useful institutions known all over the country—I believe, in all the great towns or in most of them and even in many country places—as coffee and cocoa houses, we ought to see a large increase of revenue, at least, from other sources." But that increase we do not find. That is a curious fact. I am not going to include tea, because tea, after all, is not much used in these public places. ("Yes.") The revenue derived in 1867-8 jointly —I will not give all the details—from chicory, cocoa, and coffee was £523,000. The revenue derived from the same sources in 1874-5 had fallen to £3 0 000; but then, in the first place, the movement adverse to alcoholic liquors had not then commenced, and, in the second place, a very large reduction had been made on the coffee duty, which, in 1867, yielded £390,000, but it was reduced in 1872 from 3d to 1½d per lb and in 1874 it only yielded £207,000. But while this great movement adverse to alcohol, which has been so eminently favourable to both coffee and chicory, has been at work since 1874-5, it has not produced the slightest tally in the revenue from coffee, but, on the contrary, during the last seven years, there has been a further diminution on coffee. In 1874 the coffee duty was £207,000; in 1881 it was only £189,000; and, although the chicory duty had been slightly increased, it only increased by £8,000 and did not make up the whole difference. The cocoa duty had increased somewhat, from £40 000 to £46,0 0; but the joint yield of these three articles, which in 1874 was £310,000, was only £306,000 in 1881. When we turn to tea, the case is very different. There it is not in the tea houses, but the domestic use of tea that is advancing at such a rate that there you have a powerful champion able to encounter alcoholic drink in a fair field and to throw it in fair fight. The revenue on tea, which in 1867 was £3,350 000, had risen in 1874 to £3,875,000, and in 1881 to £4,200,000. The increase of the population during that period of 14 years was 4,900,000. But there was no corresponding augmentation in the revenue from coffee and chicory. I am bound to say there is a peculiar state of the law to which I ought to invite the House to apply a remedy, and I shall lay a resolution on the table of the Committee this very evening with that view. At present every description of admixture with coffee is permitted, and we have long proceeded on the principle that the admixture of chicory with coffee was not an adulteration—that it was an admixture rooted in the habits of many countries so that people would not drink coffee without it. But of late a practice has grown up of producing all kinds of substitutes under the name of coffee (Hear, hear), and that I cannot but think, must in some degree account for the strange and singular state of the figures that I have laid before the Committee. We shall not attempt to interfere with the admixture of chicory with coffee, but we propose that it should not be allowed to introduce other miscellaneous admixtures with coffee. (Hear, hear.)

JAVA CINCHONA CULTURE.

The following is a translation of Mr. Moens' report for the first quarter of this year;—

REPORT ON THE GOVERNMENT CINCHONA ENTERPRISE IN JAVA FOR THE 1ST QUARTER 1882.

The weather during the past quarter was favorable for operations. The continuous wet weather permitted the regular carrying on of the partial stripping of trees; only in March the interval of two weeks drought obliged us temporarily to discontinue that work. There were put out in the open 30,000 Ledgeriana and 9,000 succirubra plants. The harvest obtained so far reached 45,000 Amst. lb., of which a quarter was dispatched to Tjicao—31,575 A. lb. In January, simultaneously with the original trees, many of the two year old grafts began to blossom. Although this might have been expected, it caused some uneasiness, as it was feared that the blossom might exact too much from the strength of these young trees. These were therefore carefully observed, and it is already clear not only that have they borne the blossoming well but that it is even very probable that they will also bring to maturity the fruit also, without harm to the plants. This last would be a great gain, as on the Tirtasari establishment, where these grafts are planted, there are no other varieties of cinchona but pure C. Ledgeriana. The flowers of these trees cannot therefore receive pollen from other cinchonas, and the seed ought to give exceptional plants. Among the grafts examined, in which the choice of stock was generally very limited, there are some which, although not yet one year old, are already blossoming profusely; it is to be feared that some of them will succumb to this. The chemical analyses which were performed during this quarter had still for their object the determination of the quinine yield of young Ledgerianas, produced from seed of different parent trees. The most valuable results of these investigations will be given in the next report. J. C. BERNELOT MOENS,

Director Govt. Cinchona Enterprise.

Bandong, 4th April 1882.

It will be observed that Mr. Moens evidently contemplates propagating Ledgerianas from seed obtained from grafted trees of only two years old. But it

must be kept in view that the Ledgeriana grafts were taken from trees fully fourteen years old. The case is very different, therefore, from that of common plants blossoming and seeding prematurely. When we met Mr. Moens in Java he was anticipating a large crop of seed from his old Ledgerianas. If, in addition to the fulfilment of this hope, seed is gathered from any considerable proportion of the grafted plants, we may anticipate that erelong the distribution of seed to others than Java planters may be again sanctioned. Meantime first-rate Ledgerianas are yielding seed in Ceylon.

THE TEA IMPORTS AND EXPORTS OF BRITISH INDIA.

The *Pioneer*, in a second interesting article on the annual report of the Commissioner for Assam, strangely under-rates the quantity of China tea still imported into India. Its cheapness compared with Indian tea recommended it (especially to tea-drinking natives) before the duty of 6d per lb. was removed, and now, of course, the weak China tea will be in a still more advantageous position in the matter of the price per lb. at which it can be sold. The Indian tea is twice as strong as the China leaf, and more than twice as good, but time will be required both in India and Ceylon for the formation of a new taste. Having received from the Government of India the Customs Accounts for the year ended 31st March, we are able to see what the exact figures for imports of tea into India as well as exports from that empire are. The quantity imported is ten-fold that given by the writer in the *Pioneer*, as the following figures will shew :—

	1879-80.	1880-81.	1881-82.
	lb.	*lb.*	*lb.*
From China ...	2,089,041 ...	2,534,090 ...	1,895,850
,, other countries	445,477 ...	788.317 ..	949,362
Totals	2,534,518	3.222,407	2 845,212

The average, therefore, is about three millions of pounds per annum for a population of considerably over 200 millions of human beings, and we do not suppose that an equal proportion of Indian tea is used : let us say five millions of pounds in all. The day is coming when the figures will be 50 or even 500 millions. The condition and the taste of the Hindus must first be improved, however. The Customs valuation of the tea imported, which is too high, ranges over 2 millions of rupees per annum.

Let us now turn to the figures for tea exported in the past three years, remembering that every pound of this is India-grown produce :—

	1879-80.	1880-81.	1881-82.
	lb.	*lb.*	*lb.*
To United Kingdom	37,932,094...	45,416,582...	47,413,576
,, Australia ...	85,994...	807,608...	906,762
,, other countries	155,433...	189,320...	371,387
Totals	38,173,521	46,413,510	48,691,725

The Customs' valuation of the exports was over 30 millions of rupees for each of the two first years, and 36 millions for the last. Our readers will observe the effects of the Melbourne Exhibition and the operations of the Syndicate on the exports of Indian tea to Australia, the increase being from 86,000 lb. in 1879-80 to 906,762 lb. last year. Ere long the exports to the lands of the south will count by millions of pounds.

It remains to mention that the "re-exports" of China tea from India were in each of the three years 231,111 lb., 505,029, lb. and 563,617 lb. The actual consumption of China tea in India is therefore only 2,500,000 lb., with perhaps an equal quantity of Indian tea.

In the *Madras Mail* of the 23rd, we find the following estimate of this year's crop of Indian tea :

The estimated probable crop of Indian tea this year is 51,619,000 lb. The local consumption, including the requirements of Government, may be taken at 1½ millions of lb., and, if, as is hoped, the shipments to Australia and America should amount to 2 millions, there will remain from the probable crop of 1882 about 48 millions of lb. for export to the United Kingdon.

As far as Ceylon is concerned there is reason to believe that the tea produced in the island is gradually supplanting the China kinds. In 1880 the duty levied on tea entered for home consumption was only R7,461. As the duty is ¼ of a rupee per lb., the above sum represents 29 844 lb. So that a population of 2¾ millions consumes only 30,000 lb. per annum of China tea, with perhaps 15 000 lb. of the Ceylon-grown article? The latter figure may be doubled for ought we know. In 1879 the quantity of tea imported was 78,000 lb., but as 35,000 lb. of imported tea were exported, the consumption of imported tea, ranging about 30,000 lb. seems to be going down. In 1880 73 763 lb. were imported, and only 29,844 lb. consumed. The consumption of locally produced tea ought to go up in proportion, and more than in proportion to the decrease in the consumption of imported tea.

Before closing we place here a paragraph which shews that a paper in China actually anticipates the absolute extinction of the trade in China tea :—

The *China Mail* recently noted the unprecedented increase in the sale of Indian teas during the last few years, and has predicted that the China tea-growers would have to look to it lest their Indian rivals ousted them altogether from the race. A correspondent engaged in the tea trade of China goes further than this, and asserts that the China trade will nearly disappear in five years, and entirely disappear in ten, unless the Chinese Government see fit to encourage it by a reduction in the crushing duties now levied on the exported leaf. There can be no doubt that the question is becoming a serious one for China and China merchants ; and it would be well if the authorities interested were to take warning in time. From a national point of view, one scarcely knows whether to wish most success to the Indian trade, or that carried on in China. Chinese obstinacy will probably settle the question of rivalry sooner than people expect."

MR. DE CAEN'S CINCHONA PEELING MACHINE.

Hellbodde Estate, 24th May 1882

DEAR SIR,—"Károly Fürdö," in his letter dated 15th inst., distinctly questions the capabilities of my cinchona harvesting machine. At the same time he invites correction I, therefore, challenge him to meet me here for the purpose of my proving to him how unjust as well as injurious his criticisms have been. I send strictly by Messrs. J. Walker & Co.'s adver-

isement, and am ready to substantiate it by guaranteeing a payment of R200 to the Friend-in-Need Society," if I fail at the trial I propose, if "Károly Fürdö will support his statements by a similar guarantee.—Yours truly, J. H. DE CAEN.

DE CAEN'S PATENT CINCHONA BRANCH AND TWIG HARVESTING MACHINE.

Directions for use.

Carry the harvester to a spot as nearly as possible in the centre of your day's work.

Put *all* the coolies told off to this work to cut and carry branches and twigs for about one hour; by that time a considerable help will have been collected near the machine.

Now put *one* man to turn the handle and two boys to feed as fast as possible; have never less than 12 to 15 twigs passing through the rollers at the same time, should the twigs be very small, pass them through in bundles of 10 or 12; if large branches are being harvested keep them well towards the tapering end of the machine. Change the "man at the wheel" every half hour, with one of the loppers or carriers.

When a considerable quantity has been peeled, take off from your collectors, two women, and set them to work sorting the wood from the bark. About half an hour before leaving off work, bring in all your loppers, &c., to sort what bark remains.

By this means it will be found easy to harvest at the very least 400 lb. of wet bark during the day, and this with five coolies actually working *at* the machine.

The number of loppers must entirely depend on the ground to be gone over. In a thick clearing, three extra coolies should suffice, but in open coffee land, with the trees at long distances from each other, five extra hands will be found necessary.

The harvester has proved itself capable on several occasions of peeling 80 lb. of wet bark per hour, when worked by one man and two boys. J. H. DE CAEN.

Pusselawa, 18th April, 1882.

Sole Manufacturers:—

Messrs. John Walker & Co., Colombo and Kandy.

DE CAEN'S PATENT CINCHONA BRANCH & TWIG HARVESTING MACHINE.—The above machine has been greatly improved and strengthened. A fly wheel has been attached, making the task of 400 lb. of wet bark per day a certainty. The sample of branch and twig bark produced by this invention is very superior to that obtained by any other process now in use. Price of the improved machine with fly wheel, R60 (Sixty)—nett cash.

Orders booked by Messrs. J. Walker & Co., Colombo, and Kandy, sole manufacturers.

On the recommendation of a gentleman who thought, no doubt, well of the invention, our former correspondent purchased one of these machines, and was grievously disappointed with its portability and performances. The postcard indicating that the machine was ready to be removed from Tillicoultry stated distinctly that 4 coolies would be required to carry it, and our correspondent found by experience that this number of men was required to carry it to the field and remove it from place to place. This is matter of fact, and the only question now to be settled is the weight of the machine. Will Károly Fürdö have it weighed and let us know the result? Because Mr. de Caen, in an interview with us, stated that it ought not to weigh more than 80 lb., and that in fact he himself had carried one considerable distances. Information as to the weight of the special machine will settle this question, and if the weight turns out to be far beyond what Mr. de Caen intended, perhaps that fact may largely explain its failure in action. When Mr. de Caen came to our office and got from us the name of our correspondent, he preserved a courteous tone and proposed to send a kangani to the estate to shew the mode of working the machine &c. We told him that if he did so, and if our correspondent found that he had done injustice or was in error in any respect, we felt certain he would publicly state the facts and if necessary make such amends as might be necessary. We were interested in hearing that, worked by water power, the machine had done 800 lb. of bark in a day, and we specially noted that Mr. de Caen said: "Perhaps *officinalis* twigs were put into the machine; in that case I cannot say what the effect would be, for I have never tried it save with *succirubra*." Now it is important to know if Károly Fürdö or other purchasers were informed that the machine was not adapted for *officinalis*, as they certainly ought to have been. As Mr. de Caen, on full consideration evidently, has chosen to change the tone of civility due to the public from an inventor who courts their patronage as much as from a tradesman, we beg to assure him that we see no reason why our correspondent should leave his estate where one machine has been tried and where in his judgment it has failed, in order to see Mr. de Caen, under circumstances most favourable to the experiment, try another. It is Mr. de Caen's part to go to the estate on which the alleged defective machine is and if possible to satisfy our correspondent that he is mistaken, or that the machine (which is just possible) has not been made to pattern. We can promise Mr. de Caen a polite reception and candid attention. We are also willing to publish results, conveyed in authenticated letters, obtained by other purchasers of Mr. de Caen's machines. But the weight and structure of the machine described as a failure ought, we submit, to be at once examined and reported on. As to prejudice on the part of our correspondent, we know that all his inclination, like our own, would be to accept the honoured name of Messrs. Walker & Co. as generally a guarantee for the excellence of a machine for which they are responsible. But the best engineers in the world must employ workmen, and all the work they turn out may not be equal in quality. At any rate Mr. de Caen is very much mistaken if he thinks his work as inventor and that of the constructors of his machines are not open to the freest and fullest criticism. Let Mr. de Caen prove, by going to the estate where the condemned machine lies and working it successfully, that the criticisms were "unjust" and then he will get full satisfaction. If the criticisms turn out to be just, then the fact that they are "injurious" cannot be helped. It is for Mr. de Caen, we repeat, to correct the injurious effect of the criticism in this case, not by a blustering challenge to our correspondent to go and see quite another machine, but by proving that the very machine in question is not so heavy as to require four coolies to carry it, and is perfectly capable, when properly worked (and, if any one can work it properly, Mr. de Caen can), of doing all that it was promised it would do.

CINCHONA CULTIVATION.

The letters of "Planter" and "Károly Fürdö" are well worthy of attention, although it is quite true that

there have been very varied and very puzzling experiences about cinchonas. Sometimes they will not grow in good-looking soil which has been dug over, terraced and holed, and sometimes they will flourish in indifferent looking soil, especially if it is gravelly, although only dibbled in. Our own experience with tea and cinchona at a high elevation on fairly good soil,—pronounced indeed by an Assam planter of experience to be a perfect tea soil,—was as discouraging in regard to cinchonas (mainly *officinalis*, but some *succirubra* also) as it was encouraging in respect to tea. Both plants were treated alike as regards holes, which were not so large as we could wish them to have been, but the best possible was done: distance 3 × 3 all over. The higher knolls were reserved for the cinchonas. The *whole* of the tea grew splendidly, sending down its thick long taproots through the stiff subsoil. Some of the cinchonas did not grow at all: the plants perished as soon as put out, and replanting was of no use. Others on slopes exposed to the violence of the south-west monsoon were killed off as they attempted to grow. Exceptional patches, however, flourished in the teeth of the rain-laden cold winds. Our greatest success, undoubtedly, was on the face of a hill with an eastern exposure, and up to the third year a grove of *officinalis* was the admiration of all beholders. But from the third year onward, the fatal red of the foliage told of decay, and tens-of-thousands of plants were gradually rooted up and barked, the bark selling generally at good prices. In nearly all cases of uprooted trees it was found that the taproot had not been able, like that of the tea, to pierce the clayey subsoil, but had curled round the sides of the hole as if seeking an outlet. In many cases the roots were infested with white-looking fungi which Mr. Dixon pronounced to be liverworts. We suppose it is a fact in horticulture, that if a plant cannot force its taproot downwards, but is compelled to twist it round in the soil, healthy growth is impossible? We at any rate know how fatal, in the case of coffee planting, is the doubling up of a taproot through careless planting. The fact, if fact it be, that plants grown from cuttings have no taproot, did not seem to help our plants in the stiff soil. We are now planting the knolls, where cinchona "went out," with tea, and we are encouraged to hope that in a few years hence when the powerful tap-roots of the tea plant have penetrated, opened up and largely drained the soil, and when that soil has been ameliorated by the cultivation bestowed on the tea, it may be possible to grow cinchonas with success where previously they had been a complete or partial failure. Recent experiences of planting cinchonas amongst coffee have been so encouraging that this hope is justified. Amongst the anomalies of cinchona culture, planters will have noticed that sometime the plants will refuse to grow in heaped-up top soil by the sides of estate paths, while *succirubras* at least invariably flourish in subsoil turned up from considerable depth by the sides of high roads. What "Károly Fürdö" says about cinchonas on the upper and lower sides of drains is curious, and very close draining would seem the remedy, but even this has sometimes failed.

CINCHONA CULTIVATION.

May 26th, 1882.

DEAR SIR,—I noticed, in your last London letter, that your correspondent mentioned a report, as being current there, that cinchona in Ceylon was a failure, and that it was all dying out. Now I fear we will hear a good deal more of this and see it too, if cinchona planting is carried on as it has, in many instances, been hitherto.

Many men, and myself amongst the number, have been rushing out cinchona by hundreds of thousands, merely loosening the ground with a fork, or making such a hole as may be made by giving two or three digs with a mamotie, the consequence being that the plant comes on very well for a year, or perhaps, two, and then stops growing, getting gradually thinner in its foliage until at last there is only a leaf or two at the tip of each branch.

They are generally rooted out at this stage, but the bark, half-dad, dry and sticking to the stem, will only come off in chips, and is not of much value.

A common way of accounting for this is that the second and third generation of cinchona in Ceylon is not nearly so robust as the first was, and, if this is really the case, the prospect for this product is a very poor one; but I am inclined to think the reason may be found in another direction, and that, if as much care were taken in the planting now as then, we would hear less about dying out. I consider that a hole should be cut for every plant such as would be a cut for coffee, and, if any one will try the experiment of holing and forking an acre or two in alternate lines, I am of opinion he will not be long in coming over to my way of thinking. I am not yet convinced that loosening the soil thoroughly with a long-pronged digging fork is not the most suitable way, if one could only get it done but any one who has seen coolies at this work can imagine how they do it when not under the eye of their master.

Of course, there are places on every estate, and almost in every field, where no holing or anything else will make cinchona grow past the first year or two, and other choice spots where they will grow and flourish, if merely stuck in the ground; but I speak of soils and aspects generally. One very soon knows the spots on an estate where cinchona will not grow:—

"If it will, it will, you may depend on 't,
And if it won't, it won't, so there 's an end on 't,"

and the best way is to leave that piece alone in future, and not waste plants on it. But I have under my eye here a boundary of trees, that were planted in holes, five years ago, for the most part still healthy, except in the unfavourable spots above referred to, while plants, put out with the digging fork, in the field alongside, only two years ago, are in many cases dead or in a very unhealthy condition.

I think then that a good many cinchona planters will, within the next year or two, see an illustration of the adage, "the more hurry the less speed," that they will not like, and I would stake a good deal on it, that the man who puts out this season one hundred thousand in holes will harvest more bark in five years off these trees than his neighbour will from three times the number put out with the digging fork.

This is the conviction I have arrived at from my own observation, and I would like much to hear the views of some of my fellow-planters on the same subject.

In these times a good deal of tea is being planted in unprofitable coffee, and, so far as I know, in much the same manner (dibbling in either plants or seed) and the result must necessarily be a poor, sickly and stunted bush, except in places where the soil is exceptionally good and free.

The man who is not too ambitious of a large acreage, but is careful to have the work thoroughly done, will save himself much future disappointment and loss in this as in any other product.—Yours very truly, PLANTER.

CINCHONA AND DRAINAGE.

Lindula, 25th May 1882.

DEAR SIR,—In one of your recent issues I noticed an extract recommending a hole dug *below* a cankering cinchona tree as a means of saving its life. On this principle all trees on the upper side of a deep drain ought to have the best chance of existence, as having a contionous hole below them. But my experience is to the exact contrary of this, those immediately below the drain having lived, while those above cankered off. I would therefore suggest that deep holes or drains be dug *above* the trees, and my reasons are as follows. No doubt the trees on the actual edge of the drain (lower side) benefit by the loose earth, but the plants to the distance of six, twelve, or twenty feet below (according to the lay of the land) grow equally well; there is then a well-defined line from which to the upper edge of the next drain the cinchonas have all died. What is the cause of this? The explanation I believe is that the water in the soil lodges in the top drain: it then soaks through the ground *below* the roots of the nearest trees, doing them good rather than harm, till it finds its own level (i.e. the level of the bottom of the drain) on the surface, down which it runs into the next drain, killing all intervening plants because it flows *over* their roots. I send a diagram, which, however, I do not suppose you can reproduce.—Yours truly, KÁROLY FÜRDÖ.

DE CAEN'S CINCHONA PEELING MACHINE.

Mr. de Caen's foolish challenge was scarcely before the public when the letter we publish today, from a second planter who authenticates and who records experience similar to that obtained by Károly Fürdö, reached us. He adds that he could get decent results only by discarding twigs; but we suppose that it is mainly to deal with twigs that machinery is desiderated. Our present correspondent states that the machine went out of order, as most machines are apt to do. In a country like this machinery must be very superior indeed to supersede human labour. Over and over have stone-breaking machines been tried, only to be discarded. Here is the distinct statement that, for 35 lb of bark per cooly with the machine, 65 and more were obtained by means of alavangas used like Károly Fürdö's bamboos. It won't do for Mr. de Caen to denounce such statements of fact as unjust and injurious and to publish wild challenges. He must produce countervailing facts. The experience of two purchasers and Mr. de Caen's own statement to us shew that the machine is not calculated to deal with cinchona twigs of small size; while its treatment of larger branches is pronounced not satisfactory. So stands the case now.

DE CAEN'S CINCHONA PEELING MACHINE.

DEAR SIR,—My experience of de Caen's cinchona harvester, though b tter than "Károly Furdö"s, supports his statement that it does not do the work it is advertized to do, and, by publishing the result of my trials, I hope, for the sake of the patentee, that somebody who has made it do 400 lb. or more will show us where we have made the mistake and how to get the task done. I have worked the machine off and on for a month with sometimes six and sometimes eight coolies, and the best task was 282 lb. in a day. On other days I have got 210 lb., 225 lb., &c. The day I managed to get 282 lb. I rejected all the twigs and only passed medium and large-sized branches through. These of course were succinubras as officinalis branches are nearly all too small and go through untouched.

On several days I stood over the coolies the whole day, had three men feeding as hard as they could, and, changed "the man at the wheel" every half-hour, still the average stayed at between 30 lb. to 35 lb. per cooly, and finally the bearings of the lower roller were out and the cog wheels failing to bite the top roller stood still. After this I started with two "alavangas," using them as "Károly Fürdö" does his sticks or bamboos and on the second day the coolies brought in 60 lb. to 65 lb. of wet bark each, and after a few days practice more they reached 75 lb. to 80 lb. Soon after this I had to stop barking, but next month I intend to start again, and have no doubt that, if one picks out the coolies who show themselves most apt at the work, nearly 100 lb. wet bark will be brought in by each cooly.

I was peeling branches from 3½ year old trees, and they did every size of branch with the greatest ease.

Even if the coolies, good and bad workers together, only average 70 lb. each with the sticks or alavangas, six of them will do as much as the machine is said to, so that the price R60 can never be recovered.

None of the statements in this letter are from hearsay or second-hand; and I shall be glad to be shown that I am wrong in my opinion of de Caen's harvester; still the fact will remain that "alavangas" do as well and are cheaper.—Yours faithfully,

JOHN PEEL—ER.

"A NEW FEVER REMEDY."

Under the above title the *Indian Daily News* publishes an article of more serious import to cinchona growers than all the accounts we have seen of the manufacture of artificial quinine. In cases of fever quinine lowers the abnormal temperature of the body, and believers in the germ theory of disease hold that its curative property in cases of fever is due to its fatal effect on the germs which cause fever. The causes destroyed, the effects disappear. Our readers are aware that carbonic acid gas is, in quantity, amongst the deadliest of poisons. But this is the agent which is to supersede quinine in the treatment of malarious fevers, not in the dilute form of soda-water however, but in the shape of regular doses. Dr. John Parkin of London is the inventor of this treatment, but its introduction to India is due to Dr. Charles G. R. Naylor, Civil Surgeon, of Tharawaddy, British Burma. It seems that

He claims that by the proper administration of the antidote, a complete cure may be effected in three days, but allowing two more for rest after convalescence.

Without entering into the pathology of intermittent fever, it may be briefly stated that the cause of fever is the presence of a specific poison in the blood, and that carbonic acid gas, when taken into the stomach and absorbed and carried forward to the great venous centres, neutralizes its effects in the same way as charcoal or carbon is familiarly known to arrest decay. This is the theory which Dr. Naylor has put into practice in the following and other cases. The first patient, he tells us, was his wife. The fever was contracted in Akyab in April 1879, and commenced in a remittent form which lasted a fort-

night, and was accompanied by delirium and jaundice. After this the fever returned regularly at intervals of about a month till May 1880, when the carbonic acid gas treatment was tried. Two or three doses were administered at short intervals before the accession of the cold stage, and on the fourth day the fever was gone, and has not since returned. A Deputy Conservator of Forests, who had been suffering from severe attacks of fever every three months for two years, and had tried quinine and other remedies without effect, was completely cured after a few days of the new treatment. Other cases are mentioned in which the fever has not only ceased, but the patient has seemed to resist its attacks even in malarious districts for months afterwards.

Dr. Parkin has not described any cases demonstrating the effect of this new remedy on surgical fevers, and Dr. Naylor has only been able to make one experiment of this nature as yet, in which the result appeared to be successful. The benefit derived by the use of the gas, in cases of remittent fever was found to be in direct proportion to the proximity of the period of its administration to the return or accession of a febrile paroxysm, provided that sufficient time was allowed to administer four or five doses of the remedy at intervals of about half-an-hour. In simple fever the best time was during the slight remission that occurs at some interval during the twenty-four hours. The gas is administered by dissolving three parts of bicarbonate soda in water, with two parts of tartaric acid, and drinking the mixture while effervescing. The soda and acid may, however, be taken separately one after the other with equally good effect. Should the new cure prove as generally effectual, as Dr. Naylor hopes it will, then not only will a great boon have been conferred on suffering humanity, but the Government itself will reap no small advantage. At present not only is there a heavy loss from cases of protracted fever in hospitals, particularly among soldiers in time of war, but in many instances the services of valuable officers are lost through continued fever producing organic disease, and necessitating a prolonged absence on leave or an early retirement from the service. Besides this, the cost of the new antidote is altogether insignificant as compared with that of quinine, cinchona, and other known febrifuges, so that in every way the Government have much reason to be interested in the success of the experiment. It is to be hoped, therefore, that the Government will direct its attention to the matter, and allow the experiment to have a full and fair trial

Certainly this demand is reasonable, but if effervescing draughts of bicarbonate of soda and tartaric acid have the effect of being not only refreshing in hot weather but a potent cure for malarious fever, then truly marvellous is it that the virtues of the dose were not earlier discovered.

PLANTING IN FIJI.

We are the more glad to get the letter of our correspondent A. J. S., because we have been long doomed to look in vain for anything of the slightest importance in regard to coffee, leaf-disease, or anything else connected with planting in that pretentious wind-bag, the *Fiji Times*. Even when Marshall Ward's elaborate reports on *hemileia vastatrix* reached Fiji, the only notice in the *Fiji Times* was that the reports could be seen at a public institution and the insertion of a parody on scientific description, which the editor may have deemed wonderfully witty, but which we are greatly mistaken if his planting readers found instructive or useful. If the planters of Fiji are contented with such an organ as the *Fiji Times*, that is their business. When we want information about European enterprize in Fiji, we certainly shall not look in its columns. We are not surprized to hear that all experiments directed to finding a cure for *hemileia vastatrix* have failed, and we have not the slightest confidence in Mr. Storck's much vaunted remedy. Carbolic acid is not a volatile substance, and the spores of the fungus will not be killed by a diffused smell of tar. Why Mr. Storck should now make a mystery of his remedy, after having fully disclosed his mode in the *Gardener's Chronicle*, it is difficult to see. It is clear that merely for the destruction of the spores nothing can excel lime and sulphur. The difficulty is to prevent fresh spores being blown on to fresh foliage, and, as the creation of shelter belts requires time, we fear we must just trust to time for the remedy in the shape of gradually decreasing virulence. The disease will run its course in Fiji as it has done in Ceylon and Southern India, and if the Fiji planters are wise they will direct their main attention to sugar. But without a good supply of cheap labour nothing can be profitably cultivated, and it is evident that the labour difficulty is becoming a very serious one in the isles of the south. If it cannot be overcome, rich volcanic soil will avail but little. Violent wind currents, too, form a drawback.

Having above expressed the opinion that the odour of carbolic acid, diffused in the atmosphere, is not likely to kill the spores of *hemileia vastatrix*, we think it only fair to give the following testimony of an opposite nature, sent to us by a correspondent as likely to be gratifying to Mr. Schrottky's friends:—

TUBERCULAR DISEASE.

TO THE EDITOR OF THE [LONDON] "TIMES."

SIR,—As an item which seems to me to support Professor Tyndall's letter on tubercular disease, in the *Times* of today, which also suggests a remedy, will you allow me to state in your columns that in the spring of 1871 I was a consumptive patient in Madeira, apparently past recovery; that I then tried the use of carbolic acid by my bedside as a protection from mosquitoes, and at once found that it had a beneficial influence on my lungs. I continued its use, and in the summer came to England, and have remained here, quite well, ever since. I have no doubt that the carbolic vapour inhaled destroyed the *bacilli*.—I am, sir, yours faithfully, R. R. MADDISON.

Barnsley, Yorkshire, April 22nd.

COFFEE ADULTERATION AND ADULTERATION GENERALLY.

A merchant writes:—"Here is another extract re coffee:—

Last week I protested against the vile mixtures which are sold as coffee. Mr. Pasteur, the well-known Colonial broker, has put himself at the head of a movement to put an end to this abuse. He has already memorialized the Treasury on the subject of the Treasury minute of January last, which allows coffee or chicory, and any other vegetable matter applicable to the use of chicory or coffee, to be imported, washed, ground, and mixed, under a duty of 2d. per lb. The reply of the Treasury is that the minute involves no alteration of the conditions under which mixtures of coffee and chicory may be sold in England, and that the matter should be considered rather in connection with the Adulteration Acts than with the Customs. This, I think, is reasonable. It is not the business of Custom-house officers to analyze stuff imported as coffee, but merely to levy a duty upon it. What really is wanted is an Act prohibiting the sale of any sort of mixture under the name of coffee or under any name of which coffee forms a portion. Mr. Pasteur's facts are well worthy of consideration. In February he purchased thirty-seven samples of coffee at various London shops. Only in two instances was the coffee pure; in some cases the coffee formed only 7 per cent. of the mixture. The adulterations consisted of chicory, dandelion,

dates, and finings. In some cases the compound was called coffee, in others a mixture, and in others "specially prepared French coffee." Now, what is the result? Whereas the consumption of a wholesome beverage, well fitted to advance temperate habits, is increasing elsewhere, with us it is decreasing. In 1847, with a duty nearly three times as heavy as the present one, our consumption was 37,472,153 lb., or about 2 lb. per head; it has now declined to 31,943,400 lb., or less than 1 lb. per head. Each succeeding year there is a falling-off. In 1879, the duty on coffee yielded £216,800; in 1880, £203,500; and in 1881, £199,600. The public, in fact, finding themselves only able to buy the wretched stuff which is sold to them under the name of, or coupled with the name of, coffee, are leaving off drinking it. The profits upon these adulterations are enormous. As a rule, these mixtures are sold at 1s per lb., whereas good pure coffee, roasted and ground, can be sold retail for 10d or 11d per lb. In America, the consumption is at the rate of 8 lb. per head per annum; in Germany, with a duty of 21s per cwt., it is 5 lb. per head; and in France, with a duty of 60s per cwt., it is 4 lb. per head. These facts speak for themselves.

I would recommend the friends of temperance to insist upon sharp penalties being enforced against all who sell mixtures and who couple the name of coffee with them. What we require are beverages, wholesome and agreeable, that will compete with beer and spirits. It is no use establishing coffee taverns if, by an abuse of law, we habituate people to the notion that coffee is a foul and unpalatable concoction.

The real way to have good coffee is to roast and grind it each morning, and to use at least two teaspoonsful for each cup required. The best plan to make coffee is that of the French peasants. They heat it in a saucepan, being careful to take it off the fire one second before the water boils, and then they strain it through a piece of muslin. Poor people, however, have not the time for this; they buy their coffee roasted and ground, and some means ought to be taken to ensure its purity. Years ago, when this subject was being discussed in Parliament, I remember that the late Sir Francis Baring, then Chancellor of the Exchequer, insisted that coffee was better with chicory than without it and that he always took this mixture himself for his breakfast. Tastes differ. Bad coffee, and badly made coffee, are perhaps, better with chicory, because it abates the bitterness; but I hardly fancy that even the late Sir Francis Baring would have liked a cup prepared from a mixture containing 7 per cent. of coffee and 93 per cent. of chicory, dandelions, dates, and finings.—*Truth.*

It will be a good thing if the Planters' Association would order you to reprint and dispatch to each member of Parliament (or to that portion of them professing sympathy with the U. K. Alliance and other kindred bodies), to each judge of assize, to each leading prelate and to each dissenting minister openly sympathizing with the temperance movement, and to all who take the lead in such movements, a small pamphlet embracing original articles and all extracts, &c. that have appeared in the *Observer*, bearing upon the scourge of adulteration of staple articles of food (winked at by successive governments), which scourge is without doubt the *fly-wheel* of a vast proportion of evils brought about by the intemperate use of alcoholic drinks at the present day. The people of England *must*, sooner or later, be made to feel that *they* (*i. e. the temperate portion of them*) are, in truth, responsible for the fearful evils referred to, and when their eyes are once opened to this *fact* the working man's breakfast table will then be made as pure as the rich man's dinner table (and so it ought to be), and we shall then soon hear less of the canting humbug about the crimes committed due to "drink"! -due, it will be found, eventually *to weak and wicked Governments* TRUCKLING *to the power of* licensed victuallers and unscrupulous grocers, *who* possess by far the largest voting powers of any classes in the kingdom!

I verily believe that, at the present moment, a great proportion of the crimes now so prevalent in Ireland must be placed down to the present and former Governments. A great demand has lately sprung up throughout the world for whisky. It follows, I think, that at the present time, owing to this extraordinary call (far past the powers of distilleries to meet, if really good well-seasoned whisky is to be supplied), millions of gallons of unseasoned and maddening spirit must be let loose not only upon the miserable and misguided Irish but upon even the less passionate and generally cooler headed English and Scotch. If there is no law against such vials of madness being poured out upon the people (and I believe there is not), then the sooner the English Parliament attends to such a sickening state of things the better. As it is, our gaols, our lunatic asylums, our workhouses, are being filled to a great extent by the legitimate use of immature spirits, and most of all by that legitimized demon *Fuse Oil.*

P. S.—Surely no whisky or other spirit under a certain age should be allowed to be retailed under the very heaviest of penalties.

MANURING EXPERIMENTS.

(*From our Aberdeen Corresspondent.*)

I cull the following from the annual reportby Mr. Jamieson (Agricultural Chemist, Aberdeen) on the manure experiments conducted by him at the experimental stations in Sussex, submitted by him to the meeting of the Sussex Association for the improvement of agriculture. It is interesting as giving the finishing blow to the long controversy, the "battle of the phosphates":—

RESULTS OF EXPERIMENTS ON TURNIPS WITH VARIOUS PHOSPHATES.

Number of Plants.	Weight. When pulled.	After closely topping and tailing, washing free of sand, and drying externally.	After thinly slicing, drying on kiln, and grinding to flour.	After deducting the remaining traces of moisture.	Net average of dry produce.	
	lb.	oz.	oz.	oz.		
80	40	592	75½	71·29	82·93	Ground Coprolite.
85	45	736	101	94·58		
88	44	736	94	87·49	85·87	Ground Bone Ash.
89	50	752	88⅔	84·25		
83	52	816	102⅔	95·68	87·52	Superphosphate.
87	51	784	84½	79·36		
72	11	24	4½	4·12	3·60	No Phosphate.
69	5	20	3½	3·09		
88	50	736	93	86·67	85·34	Steamed Bone Flour.
89	44	704	89	84·01		
86	43	704	86	79·56	79·80	Coprolite and Steamed Bone Flour.
85	43	670	84½	80·04		

So nearly equal in results are the different forms of phosphate used, and so doubtful are the slight superiorities when the individual results are examined, that it would be wandering from economy to purchase superphosphate when coprolite provides the same quantity of phosphate

at half the cost. (It may be well to explain that both substances are about the same price per ton, but coprolite contains about twice as much phosphate as ordinary superphosphate.) So important is a good start, however, that some more quickly acting form of phosphate should accompany the slow coprolite. The rapid start by superphosphate we have seen was somewhat deceptive; the promise at first held out was not maintained: on the other hand, bone flour gave a start not much behind, and its action was more continuous. This is precisely our experience in Aberdeenshire. Five years later on, however, it was found that the superphosphate augmented a disease well known as "finger-and-toe" disease, but more correctly a club-root disease—it is distinct from the maggot tubercles so common in the south of England. On the whole, considering the action of all these phosphates in the field, considering their composition and their price, the most efficacious and most economical form of phosphate appears to be, in Sussex as in Aberdeenshire, a mixture in equal parts of steamed bone and coprolite, both ground to a floury state.

INDIAN TEA IN NEW MARKETS.

If anything would justify the attention which has been given to the subject of opening up new markets, it will be found in the news received by us last mail from Australia, and in the Report of the Tea Syndicate which we give in another place. The considerable number of packages offered in Melbourne, at the last public sale, were not only all sold, but eagerly taken up, at improved prices all round, and several lots changed hands at a profit; while the trade now, there quite look forward to these Indian tea sales. When such a result has been arrived at in so short a time, we may fairly congratulate ourselves, and feel justified and encouraged in making still further effort; for we may be sure that the liking for Indian tea in Australia is now well rooted, and will spread with rapidity. Already we hear complaints that no public auctions of Indian tea are held at Sydney, and orders from there for several thousand pounds' weight were a short while back sent to Melbourne. Mr. Sibthorpe, in his report on the Australian market, was disposed to discredit the chances at Sydney, although *why*, we at the time, as now, could not understand. Leisure did not permit him, perhaps, personally to experiment,* and he thus had to take very much for granted what people said; and the fact is, at the time, not very much confidence was felt regarding the future of India tea in Australia. A variety of circumstances, however, fortuitously happened † to spread the renown of our teas much more quickly than people had dared to hope for, and the result is now that they are being eagerly inquired for, from all parts of the Colony; and we may look to find a steadily increasing demand, which shall in no very distant time amount to quite an appreciable figure.

We do not think that planters have hitherto been so jubilant at the position reached as they fairly should be: but it is an Englishman's privilege too grumble; and those interested in Indian tea have forst long had *cause* for grumbling, that they cannot all a once get out of the habit. The complaints we hear, however, appear to amount to this:—that it is a long time before owners see the colour of their money. Well, this has been so no doubt, and in the initiatory stage of affairs it could not well be otherwise; but the drawback will diminish, as time goes on,—although, of course, so long as the teas of all gardens are bulked by the Syndicate, there is no obtaining, as in the case of direct home shipments, Advances. It is a long way from the garden to Melbourne (before leaving Calcutta for which place the teas have to be collected, bulked, and repacked), and sales are not, in Australia, weekly as with us, nor is the payment by buyers, we fancy, so prompt as here. Then when remittances *do* reach Calcutta, there is necessarily some delay, owing to the partitioning of the amount among so many. Of course in case of large public companies, the inconvenience is not felt much, but we can quite understand why there should exist amongst private owners some little soreness at a good deal of weary waiting. However, as we say, the thing is to a certain extent inevitable, and people must find their consolation in knowing that all share alike, and that their money is safe,—which might not have been the case had they had to trust to unknown and irresponsible agents at so great a distance.

Thus much for the Australian market. Now as to America. It will be remembered that it is only a month or so ago that encouragement held out to us, there, was not of the heartiest description; and we were reminded that progress would be very slow, and success by no means certain: while we were told to prepare, at any rate for preliminary loss. Well, here again we have been agreeably disappointed. The latest advices report a decided inquiry for our teas, and a brightening prospect,—the more so as Japan is losing her hold on the American market, and even is seriously beginning to question the desirability of continuing the trade. Her manufacture has so deteriorated that her teas no longer fetch remunerative prices; and, with the apathy of orientals, the Japanese seem prepared rather to let things elide than to bestow the requisite care and expense to restore to themselves their former position. We showed in a recent article what a prospect was thus opened up to this country: and indeed the effects of the change have already begun to sensibly manifest themselves. It now remains for us to seize on the opportunity with vigilance, earnestness, and *intelligence*. There is now reason to believe that America will follow speedily the example of Australia, and become in time a firm patron of Indian tea. The hands of the Calcutta Syndicate should therefore be strengthened in every possible way, to enable them to exploit the market on a sufficiently liberal scale; for it is no use trying to create a demand if, when it comes, you are not in a position adequately to meet it. Any doubt on this point existing in the minds of the American trade would be fatal to our future permanent success. We do not mean, of course, that India cannot give America all she is likely to ask for,—provided the requisite organization exists, adequately supported—but what we do mean is, that if supplies of tea to the Syndicate fall short of possible requirements—which seem likely earlier to be much larger than was originally expected—we should lose the vantage-ground we hope to gain; for it must be borne in mind that the Syndicate is not a speculative public Company, able to supply itself with stock from the open market. Such is against the fundamental principles of the body, which seeks to act as the *pioneer*, only, in opening up new markets,—depending entirely for its *supplies* upon the tea industry. The larger, therefore, the support the Syndicate receives, the greater will be its power for achieving successful results. * * *

The necessity is that a "Bulking Company" should be formed to take over the business of the Syndicate when they decide to continue no longer, and that this Company should work on the lines laid down by the Syndicate, whose experience—so valuable—has been

* But we *know* that he did his best, taking special advantage of an agricultural show in April 1881, to introduce Indian tea. He complained to us of the immovable apathy of Sydney firms. There was no firm of Henty & Co. there and no J. O. Moody. Mr. Jas. Inglis was acting as Commissioner for India in Melbourne. He is now in Sydney, and, aided by Mr. Pitt Brown, is working zealously in the interest of Indian tea.—ED.

† "Fortuitously happened"! Messrs. Moody, Inglis and others pressed the intrinsic merits of Indian tea, pointing to analyses by Newbery and Dunn; and they succeeded.—ED.

gained at such trouble and expense. Failing something of this kind, we fear that the efforts of the Syndicate—so successful as they have been—will fail of *permanent* effect. We want their practice pursued and persevered in: and if this be done, the position of Indian tea should be assured in the outside markets of the world. —*Indian Tea Gazette.*

THE ASTRONOMER OF NEW SOUTH WALES ON RAINFALL.

One of the most pleasant incidents of our visit to the Australian colonies was that of travelling from Sydney to Melbourne with Mr. Russell, the New South Wales Astronomer. Mr. Russell stands high as a keen but cautious observer, and we were not surprized to find that he was no believer in the theory that rainfall could be increased by covering plains with trees. On the other hand he was sanguine as to the grand results to be obtained from bringing to the surface the stores of water which are hidden under thousands of square miles of arid country in Australia. The following paragraph in the *Sydney Mail* shews what the conditions are by which, in Mr. Russell's opinion, the deposition of rain from the atmosphere can be influenced :—

Mr. Russell's presidential address at the annual meeting of the Royal Society contains a reply to the "rain doctors" that will be accepted by the intelligence of the public as conclusive, however much it may be cavilled about by those who, in accepting, it, would find cherished prejudices cut away or some portion of a profitable occupation gone. Mr. Russell's effort is to enable us "to get some notion of the forces at work in producing rain, and what it means if we try to interfere with them." The only one of these forces, which is in any way accurately understood, is the heating power of the sun's rays. To affect or control the rainfall we must change the temperature of the atmosphere, which will be most simply effected by a process of elevation. Familiar illustrations of the truth of this theory are afforded by comparison of the average rainfall at Windsor and Rurrojong. The summit of the hill gets 53 inches of rain for every 33 that falls in the township 1,800 feet below. Thus the same atmosphere being lifted 1,800 feet deposits 60 per cent. more rain. Hence it may be argued that in any cloudy but not rainy time the uplifting of the atmosphere some 2,000 feet would cause condensation and produce rain. The force requisite for such a work is the only point to be considered, and this is very clearly set down. Mr. Russell asks us to suppose that we desire to effect a change in the rainfall of Sydney to increase it by 60 per cent. and having calculated all the opposing forces to be overcome, he estimates that it might be accomplished by the burning of 8,000,000 tons of coal per day. This estimate is arrived at after some study, and is probably correct; it may be at least accepted as reliable data by those who desire to control the operations of Nature in the distribution of rain. The part electricity plays in the suspension of clouds, Mr. Russell tells us, speaking *ex cathedra*, science has not been able to ascertain. Franklin's experiment is often quoted, but the facts of that experiment are strangely overlooked, for it goes to prove, as does that of Crosse, at a later time, that lightning can be freely drawn from a cloud without producing rain. In fact, the question remains open to philosophers: Has electricity much to do with rain? Many instances are quoted of great explosions and vast conflagrations, some of which have been followed by rain, but the majority of which have not; and it is practically proved that it is quite impossible to get enough evidence together to establish the feeblest theory. The matter is dealt with in a clear and scientific manner, and is satisfactorily placed with those things that had better—by the present generation, at least—be left at rest.

Hills and mountains are the great capturers of moisture in the atmosphere, and by a curious law, rainfall generally increases with elevation up to a certain point, generally to 4,000 or at the very utmost 6,000 feet. The quantity then rapidly decreases, and a mountain may present the phenomenon of a deluge of rain on its middle portion, while at its base and on its summit equally the sun shines through a clear atmosphere.

NEW PRODUCTS.

From an article so headed in the very able paper recently started, *The Indigo-Planters' Gazette*, we take the following extracts :—

Messrs. Cantwell & Co. of Calcutta, have related in the columns of the *Englishman*, that they "procured some of the aloe plant leaves, many of which were over six feet in length, and subjected them to their patent process for extraction of the fibre. A sample of the fibre taken from them was sent to London, and by the last mail advice was received valuing it at £28 per ton, and offering to take any quantity of it at that price. The advice also stated that the highest price that any aloe fibre has hitherto realized in the London market was £16 per ton, so that the Indian sample is nearly double the value of that at present obtainable in the market."

The subject of timber trees and the supply of woods is a very important one, and specimens should be selected with discrimination. Beside the specimens of leaves, flowers and fruits, there should be a horizontal section with the bark attached of the whole tree, about six inches thick; a plank about 3 feet long taken through the centre, and also a similar one shewing the sapwood. These will allow of judging of its applicability in carpentering, &c.; also two or three bars about 2½ square and two to three feet long, and cut from sound wood. These billets will enable the strength to be ascertained, the breaking weights of woods being generally tried with special instruments, with pieces squared accurately to 2 inches and a length of 16 inches. A piece, when turned in a lathe, but not varnished or polished, shows its applicability or otherwise for ornamental work in which lustre, grain, or figure, and colour are the chief disiderata. Notes too should be made of as to whether the trees are liable to insect attacks, the distribution, numbers, height to first branches, circumference, whether crooked or traight, rate of growth when at full age, amount of seasoning required and the available carriage.

Woods likely to be useful in ship-building, for railway sleepers, in house construction, for cabinet work and engraving, showing them by a horizontal section with bark attached, about six inches thick or less; a slab from the centre, and also from the sap, and two or three billets 2½ inches square, 2-3 feet long from sound wood, so as to show figure, grain, lustre, colour, &c. They should not be varnished or polished. Information as to whether quick or slow growers, size, natural age, liability to insect attacks. The roots and boles are often useful for ornamental work.

TEA SYNDICATE.

To the Editor of the Englishman.

SIR,—I have read the article in your issue of 4th instant, with reference to the operations of the Calcutta tea Syndicate in Australia and America, and beg to send you the enclosed circulars which have been issued lately by the committee, and which will, no doubt, be of interest.

You will notice that the Melbourne Agents of the Syndicate strongly recommend the committee to continue their shipments to that quarter, and this is the view the committee themselves have taken, for, although private shipments are increasing, still complaints are received of the great length of prompt customary in the colonies, and of the heavy charges *

* The heaviness of the charges have greatly hindered shipments from Ceylon.—ED.

which are usually made. Until some change have been brought about in these matters, it is not likely that merchants will find it to their interest to go very largely into the trade. The Syndicate has been placed upon more favourable terms in both respects, and returns are now being received much more quickly than before, but the committee have brought these complaints of private shippers to the notice of their agents in Melbourne with a view to some changes being made which will lead to an active continuance of the trade when the time comes for the Syndicate to withdraw from it.

I also understand that Mr. A. B. Inglis, who has lately left Calcutta on a visit to Australia, intends to take up this subject on his arival in Melbourne.

With regard to the American demand, I may state that the advices of the Agents of the Syndicate are most encouraging as to the future prospects of the trade in Indian teas. The quantity hitherto shipped has not been large, and will, unfortunately, not be sufficient to last till the first shipments of the new crop arrive from this side, but the committee hope to be able to send forward full supplies this season. Upon the strong recommendation of our New York Agents, the committee have sanctioned a liberal expenditure for advertisements in all the principal newspapers throughout the United States, and all that is now required is, as you suggest, that gardens should make ample contributions of tea to meet the demand which will no doubt follow.

A. G. WATSON, Honorary Secretary.

Calcutta, May 6th, 1882.

MORE ABOUT FEVER AND ITS CURES.

The Calcutta *Englishman* contains the following article :—

"The *Indian Medical Gazette* for May contains amongst other interesting articles a précis of operations performed in the wards of the First Surgeon, Medical College Hospital, during the year 1881, and the report of a valuable paper read before the Calcutta Medical Society by Babu Rakhal Dash Ghose, L.M.S., on the use and abuse of quinine in fever. Criticism or notice of hospital operations are scarcely desirable in our columns ; but our readers may care to know something about fever and quinine from a native practitioner who has had long experience of both. In all cases of intermittent fever, Babu Rakhal Dash Ghose says quinine stands pre-eminent in efficacy and success. Chronic intermittent fever, however, is seldom benefited by quinine, and in complicated malarious fevers which have been neglected it is useless. The formula of Sir Ronald Martin in cases of spleen, in which quinine does little good beyond allaying the fever, he has found very effectual in most cases.

"This receipt he varies in obstinate cases of chronic intermittent fever by adding *Liqr. Arsenicalis*. The writer of the paper makes the somewhat astonishing statement that almost all the diseases of Bengal become tinged with *malaria*, and that the use of quinine in typhoid and eruptive fever of all sorts is desirable, especially in the case of the latter, when the eruption has been fully developed. It may be within the recollection of our readers that two Italian *savants* some four years ago claimed to have discovered the malarial germ in a microscopic fungus found in the Pontine marshes of Italy. Since then little has been heard of the malarial germ, till recently a M. Laveran has claimed to have found in in the blood of patients suffering from malaria a remarkable parasite which he affirms is the genuine cause. We give below the entire statement from the *Scientific American* :—

"Mr. A. Laveran has found in the blood of patients suffering from malarial poisoning, parasitic organisms very definite in form, and most remarkable in character ; motionless, cylindrical curved bodies, transparent and of delicate outlines, curved at the extremities ; transparent spherical forms provided with fine filaments in rapid movement, which he believes to be animalcules ; and spherical or irregular bodies, which appeared to be the "cadaverie" stage of these, all marked with pigment granules. He has also detected peculiar conditions in the blood itself. During the year that has passed since he first discovered these elements, M. Laveran has examined the blood in 192 patients affected with various symptoms of malarial disease, and has found the organisms in 180 of them, and he has convinced himself by numerous and repeated observations that they are not found in the blood of persons suffering from diseases that are not of malarial origin. In general the parasitic bodies were found in the blood only at certain times, a little before and at the moment of the accession of the fever, and they rapidly disappeared under the influence of a quinine treatment. The addition of a minute quantity of a dilute solution of sulphate of quinine to a drop of blood sufficed to destroy the organisms. M. Laveran believes that the absence of the organisms in most of the cases (only 12 in the whole 192) in which he failed to find them was due to the patients having undergone a course of treatment with quinine.

"Whether the germ of malaria be a fungus, a parasite, an organic germ of some sort, or a superabundance of carbon dioxide and other exhalations and a consequent deficiency of oxygen in the air breathed over malarious districts, this at least is certain, that the magnitude of the loss of life from what is called fever in India has attained such dimensions as to warrant, if not a special commission of experts to examine and report on the subject, at least that every practitioner, who has any experience of "fever," should give some time to its study and keep a note of his experience that it may be compared with that of others.

"The discussion on the paper above noted has been adjourned. If we are not too late, may we suggest that a committee of the Calcutta Medical Society should be appointed to report on the fever item that figures so largely and so invariably in the mortuary returns ?"

[There can be no doubt that the great remedy for fever is quinine. Next to it in value is arsenic, but the latter requires great caution in its use, and should be taken only when prescribed by a physician. The arsenic eaters of Styria become ultimately the most fearful wrecks, more pitiable, if anything, than the victims of opium and alcohol. Our readers have heard the story of old James Reed of Rajawella, who discovered the proper dose of arsenic, after twenty coolies had succumbed to over-doses !—In the severe cases of remittent fever, where quinine fails, there is probably lesion of the liver or some vital organ.—ED.]

REANA LUXURIANS.—An Indian correspondent writes : —"Your correspondent, who has tried the seed of the 'Reana luxurians,' should try parching it or roasting, when he will find it as edible as Indian corn. But Reana is not worth growing for its grain, as the stalk becomes hard and cattle cannot eat it then ; when green, and before the seed forms, it is very good for fodder : in fact nothing can be better except the imphee or sorghum, which is capital fodder, besides giving abundant grain, which also is very good as a food grain for man and beast, if boiled, or parched, or ground down to meal. The Reana has one advantage, that it is not poisonous to cattle at any time, whereas the sorghum is poisonous at certain times of the year, before it is full-grown."

VICISSITUDES OF THE PLANTING ENTERPRISE IN CEYLON:—THE TROPICAL SWING; DEPRESSION AND PROSPERITY.

Nothing succeeds like success. The timeworn aphorism has been marvellously illustrated again and again, in the history of planting and the experience of planters in Ceylon. Men with no special superiority of judgment, prudence, or ability, have been carried in on the full tide of prosperity to competency and fortune which they would not have dared to dream of but a few years previously; while their neighbours, missing, through no fault of their own, this rare good luck, have ere long found themselves stranded high and dry, watching the ebb-tide as it receded from them. Men have bought and planted land together, with the same care and judgment; one it may be distrusting fortune has sold prematurely at a moderate profit and afterwards been called a fool for his pains; a second has not had the chance of selling until the periodical inflation and "rush" have set in and then he acquires "fame and fortune" without asking for them; while a third who has never had a good offer so being perforce compelled to stick to the land, finds himself ruined in reputation as well as pocket when the cycle of depression, distrust and poverty of capital sets in. This is a picture of experience where speculation not cultivation was the primary object in view. Or, again, we have had the *bona fide* planter opening forestland and trying in vain to sell that in which he had lost faith, in order to possess himself of property in another and, for the time, favourite district. "Trying in vain" to sell his much-depreciated venture, to his great good-fortune; for a few more years shew that the once "favourite" district is a delusion, while his own despised property proves a perfect gold-mine to its owner. Such are some of the vicissitudes of recent years, and they are no mere idle speculations, for our illustrations are based on actual occurrences now in our mind's eye. A very short time ago the most prosperous coffee plantation "of the (past) season" was condemned in our hearing by some of the oldest and hardest-headed planters in the country, as never likely to do anything for its owners, while other places now worth not half its value were cracked up to the skies. Two of the most practical of managers and inspectors decided together about a dozen years ago that the Dimbula coffee plantation which is probably to give the best crop of the coming season—and which has yielded satisfactorily if not handsomely ever since it was opened—was not worth having in forestland at £2 per acre. Again the district which is at present deemed worthy of chief condemnation by financial and inspecting critics was but a few years ago in everybody's mouth as shewing the finest coffee in the island, and among its chief depreciators are some who, while carving their own fortunes out of it, were loudest in its praise. Need we say that Maskeliya is referred to, or remind our readers of the exuberant language used by planting visitors, usually chary of their words, to describe the clearings on "Peria Maskeliya," under Mr. Jardine's care, when the Peak Valleys were being felled on all sides. In the present writer's twenty years' experience he can recall no such unanimity of opinion among planting authorities as was found less than ten years ago in reference to the suitableness of the quarter referred to for coffee, and if there were any of the then authorities and pioneers who in their heart of hearts had no belief in the coffee they were planting, being a success, surely these men above all others are worthy of condemnation?

The dark days of depression, wet seasons, leaf-disease and grub have wrought a woeful change. Estates sold not many years ago for prices then deemed well within their value, and on which cultivation has been kept up and extended, leaf-disease fought and grub repelled, are now estimated at from one-third to one-fourth the previous selling price, and no doubt taking the probable crop of the coming season, and the returns of the past two or three years as a guide, no other result could be arrived at. Nevertheless in all probability it is the thing we have seen in the past, which (*malgré* all the enemies of coffee) we shall yet see in the time to come. In 1845, wild speculation, followed by a heavy fall in the price of the berry and a collapse of credit, arrested planting enterprize in Ceylon for a time, and when from the ruins a fair and promising industry began to be established, it was gravely argued by the chief scientific authority of the day that "bug," then (in 1850) almost universally prevalent, would never quit the coffee tree and would wear it out eventually in Ceylon. A period of prosperity ensued however to be followed by a smart financial shock in 1855-6 (the eleven years' cycle) which shock, after another prosperous run, was repeated with even greater effect in 1866-67. In the latter years, commercial and planting disaster prevailed to a considerable extent, and the most striking picture of woebegone misery to be found in Ceylon (according to Mr. Boustead, Senior) when he visited the island about that time, was "the man who owned a coffee estate"! The financial crisis and period of depression which commenced, after the usual interval, in 1878, has proved to be more trying and prolonged than any of its predecessors, save, perhaps, that of 1845-50, and the few "wise men" who, taking Josh Billings' advice, prophesy after the event, have had a great innings, building up reputations for keen sagacity and foresight on perhaps the ruin wrought among their neighbours by the failure of crops and pressure of the times. No doubt a stern lesson had to be read to check speculation, and to teach men what they had failed or refused to learn from any of the previous successive crises, namely the unwisdom of turning hundreds of miles of a mountainous country with varying climates and soils into cultivation with one product, when others equally profitable and more suitable were offering for their acceptance. But all the same, it is too much to find "professionals" who themselves did nothing to lead the way in "new products," denouncing in unmeasured terms 'the mad folly" of the planters on whom they are now sent to sit and report. To persistently cry down plantations and the work of a dozen years back as useless seems to us, parallel to the case of the man who having murdered his father and mother, appealed to the Court for mercy because he was an orphan. No one having a due regard to past experience, and to the many advantages which attend the planter in the present

day to balance against the immediate serious evils which beset him, dare picture the future in sable colours only. There is a silver lining to the dark cloud of depression and though it may be

"The hidden but the common thought of all,"—

or at any rate of a majority, that "coffee" is in the "sere and yellow leaf" in Ceylon—never to regain its potency—we fearlessly avow that we are not among the number of those who would confine "the silver lining" of the future to "new products" alone. No one dare say we undervalue any of these; for where but in the columns of the *Ceylon Observer* was the cultivation of cinchona, tea and cocoa urged on planting attention in season and out of season, during the years when as yet "king coffee" ruled the banker, merchant, would-be proprietor or pioneer, with undisputed sway? Not another acre of Arabian coffee would we see planted, until the "more light" which apparently only time can bring, is thrown upon the course of the leaf-fungus; but we refuse to rush to the other extreme and say that the coffee land now bearing from seven bushels of berries per acre downwards, is to be considered past recovery. Let us again illustrate. We have before us the possibility—not a few would say probability—that 500 acres of Maskeliya coffee all in one sheet of "living green," valued the other day at £6,000 (against £24,000 five or six years ago), may (should February prove dry as in 1878) yield in *one* season as much crop and profit as will clear the whole valuation. We do not find fault with the estimate on that account; but we do say that mortgagees who can afford to wait, more especially when they have evidence of new "products" being zealously and judiciously cultivated in addition to the coffee, ought to be loath to consider and cast aside their security as worthless.

We have referred above to the several crises in the past history of the local planting enterprise. Perhaps a few authentic instances of the vicissitudes of property will best illustrate what "coffee" has already passed through. In 1868, at the close of a period of severe trial, we asked two gentlemen of large and varied experience to relate what they knew, and so to afford some further evidence of "truth being stranger than fiction." One of our correspondents replied as follows:—

"I could, as you suggest, by raking up my reminiscences of the last 20 years, give you some curious facts illustrative of the unsettled and changeable value of coffee properties in Ceylon. This arises too from a variety of causes, frequently of a description over which neither buyer nor seller can have any control nor with which the character or condition of the estate has anything to do. A run upon a district or a run from it may raise or depress the value of properties. An incursion of rats, or an invasion of bug, may depreciate to an extent hardly credible a very fine plantation. A scarcity of money here or at home, or *a fall in the market, will lessen* to an equal extent the worth of an estate, while a panic will sometimes depreciate it in much greater proportion. On the other hand, a bumper crop, a beautiful looking estate, a convenient locality, or a favorite mark, will, in an equal ratio, secure it a fancy price."

From the goodly number of examples then given, we reprint a few for the benefit of our present readers:—

"Example No. 1, consisting of about 100 acres old coffee and some 300 acres jungle and abandoned land was, when I first knew it, leased by two gentlemen for £5 a year, at which rental they lost money! It was afterwards purchased by one of them for £15, was partially manured and sold within a year for £700! In a few months more it changed hands again at £1,200! Subsequently it was bought for £1,000 and by the same party sold after a year's working, with a very showy crop on the trees, for £6,000! Of this price, £3,000 was paid in cash and, the buyer failing, the seller took it back for the other £3,000,—then leased it to another party for ten years at £600 a year. That party failing during his lease, it was sold for something under £3,000.

"No 2, in the same district, and on the high road containing about 100 acres good old coffee, considerably neglected; 100 more, abandoned; and probably 300 good standing forest—was sold or rather thrown away for £100. After a few months it changed hands at £700. Again in two years it brought £14,000. It has since ruined the last buyers, and were it in the market now, might not probably bring £7,000.

"No. 3, containing about 800 acres fine forest, was opened in a new district, upwards of 20 years ago. Shortly after, with about 50 acres good coffee, it was sold for £800: neglected again and almost abandoned it sold for £200: the district was then decried and deserted. It was re-opened up to about 500 acres by the purchaser at £200, who then sold and retired with about £16,000 in his pocket, the result of the cultivation of that property. It has since, when more enlarged, and improved, changed hands at £28,000, and the district is now one of the most favored in the country.

"No. 4, contained 100 acres very fine coffee, and about 500 excellent forest; but the bug had clung to the estate for several years, and shortened its crops. It was also in a district far from a shipping port, and then consequently in low repute, although now a favorite district. It was sold at Fiscal's sale for £300. Two years afterwards it changed hands at £700. It was opened up to 250 acres by the new purchaser, who, after several years working and it having cleared itself, sold it for £16,000.

"No 6, containing 120 acres coffee and 89 forest, was a perfect picture of a place—and was like an oasis in the desert: the only estate then in its district that had not been in whole or in part abandoned. The district itself being very much blown was much run down, and almost deserted.

"It has since rallied—many sheltered nooks having been found in it. It is believed in again, and now contains some of the finest estates in the country. The one in question, at the date of my first acquaintance with it, was bought for £3,000. It was perfectly clean, and in fine order; but bug unfortunately overran it, and hugged it closely for several years. The proprietor, fearing it would never leave him, sold the property for £1,700. 80 acres were added to it by the new proprietor. The bug left the estate; but it had no roads nor permanent buildings. He, however, binding the lessee to erect these and manure the whole estate, leased it out shortly after for 10 years at £1,000 per annum. This lease is still running.

"No. 9 was conveniently situated in what was then thought a good district. It contained about 100 acres of coffee and 50 good forest. In 1846 £5,000 were offered and refused for this property. Yet in 1848 it was knocked down at public auction for £250 and everybody thought the purchaser had made his fortune. But it was not so. His first crop sold in London at 35s per cwt., and after working the estate with great economy for 4 years and planting up the spare land, he cleared out of it with a loss of £400. Those were ticklish times and bold was the man who ventured to open new land then. An estate was valued exactly in proportion to its immediate returns—coffee

in cultivation only being counted; and no allowance whatever made for available land, were it ever so good or so extensive.

"No. 11, in the same district and about the same period, an estate all in cultivation but neglected, sold for £250; the roof on the store was worth all the money. But such was the prevailing distrust and impecuniosity that few cared to attend such sales; but those who did so frequently came in for bargains. This was a case in point. It was purchased by a native of small means then, but who afterwards (dating his rise from that purchase) became in his own particular sphere a star of the first magnitude—became owner of many and varied properties; but who becoming infected with a speculative mania bought at every sale on chance lands of which he knew nothing, till one day he bought too much; and his decadence was then more rapid than his ascent. This estate after many years of good bearing and remunerative crops was sold last year for £7,000.

"No. 14, situated in the once despised district before alluded to, contained about 800 acres of land, of which 250 or thereabouts had been planted with coffee and on which the proprietors, both resident but inexperienced, had expended *of their own money* £8,000, and as much more as they could draw from their agents, before the crash of 1848 put drawing beyond their reach. The estates adjoined and were within 6 miles of a great trunk road. The soil was excellent and the coffee grew remarkably well. Most of the remaining forest was available. Sold by auction at the above panic period they realized £220. They have since been worked up—have yielded good crops—and are now worth probably from £10,000 to £12,000.

"No. 18.—Disaster followed disaster in coffee-planting from 1847 to '51. And when the atmosphere cleared up, many a timid holder sacrificed, at the first bid, a valuable property. It was then that a native offered a random sum of £250 for an estate of 300 acres forest, and 120 acres coffee, which had been cultivated and abandoned, resuscitated and re-abandoned, for the previous 20 years. The offer took, and the property changed hands. £450 were immediately given the lucky buyer for the forest land. The coffee he worked up a little, and in a few months sold for £2,400."

How many examples to add to our list are to be produced by the present period of depression?

The strict, we suppose unprecedented, economy exercised in respect of all items of estate expenditure is a most encouraging fact to the capitalist and mortgagee of the present day. We do not refer to the comparative absence of outlay on manures, for that is rather a matter of regret; but we have been greatly pleased to note the determination manifested upcountry both by individual proprietors and superintendents, to keep down anything approaching to unnecessary expenditure, to secure good work for the money paid, and to do all in their power with new products to supplement the present deficiency in coffee. In many cases we are glad to learn how cinchona bark will prevent a collapse of credit and failure of ways and means. In such a season as this, the harvesting of from three thousand to five thousand rupees' worth of bark, on average-sized plantations, more especially from the mere shaving of trees, will be the salvation of the coffee planter. There are other cases where the cultivation of large plantations will be fully provided for this year by cinchona, as much as R50,000 being netted for cinchona alone. The proprietor of some thousands of promising trees is said for the second time to be making an income of R5,000, by shaving his bark. In other cases tea has come to the rescue, and in a few, cardamoms have done wonders. The activity, self-denial and ingenuity displayed on all sides by the majority of our planters have never been surpassed in the experience of any agricultural community, however much tried, and while we earnestly hope and believe that Ceylon coffee fields will yet reward the patient industry of their cultivators, we cannot but warmly applaud the spirit of scores and hundreds of men now anxiously supplementing the old, by the new, products with all the skill and means at their command. Many of them have given up not only their luxuries, but absolute "comforts," almost necessities of their daily lives—in order the more fully to put in practice the advice of the poet:—

To catch Dame Fortune's golden smile,
Assiduous wait upon her,
And gather gear by every wile
That's justified by honour.
Not for to hide it in a hedge,
Not for a train attendant,
But for the glorious privilege
Of being independent.

May the ambition of the "poor but industrious" planter of the present day, who takes these words for his motto, be more than realized!

WRIGHTSON'S AGRICULTURAL TEXT BOOK.*

This book was intended to meet the requirements of the Science and Art Department in science subject, XXIV, Principles of Agriculture. This important subject was first encouraged by payments from the Science and Art Department in 1876, and we hope the time may soon be when this subject shall be one of the extra subjects for grants in Ceylon. This text book of over 200 pages is divided into four parts. The first of these treats of the soil, its origin and formation as well as its diversified chemical composition, and tells us how soils may be improved when their vigour runs down—how their physical condition may be best improved by proper drainage and tillage. Ceylon is at a very low ebb in this matter as in many other things; they have the art of producing certain things, but they lack the science. It also tells us how the dormant or inactive constituents of a soil may be brought into a state of inactivity.

Part II discusses the ordinary manures in general use for maintaining or bringing up soils to a proper chemical strength and how and at what times such manures are best applied. Many of these remarks are applicable to Ceylon, but a great many require modification to adapt them to different circumstances of a tropical cultivation. Lime (not really a manure, but strictly speaking a corrective and a liberator of inert matter) occupies several pages. This substance is very much needed in our Ceylon soils. Other manures are also discussed, and, while writing of this, the Ceylonese idea of burning their lantana, scrub, &c., and so clearing their ground for planting, but before doing so sell the gathered up ashes to planters, reveals a wonderful ignorance. The best and most useful of all manures is cattle, when it can be obtained.

The next part takes into consideration the rotation of crops. This, however, on the hill districts of Ceylon, is not applicable, save on many places where the bad coffee is giving place to cinchona, &c. In the low districts many useful and paying crops might be grown and a system of rotation could easily be adopted.

The last part is devoted to the considera ion of the

* Wrightson's Agricultural Text Book. (Collins: Elementary Science Series.)

live stock. The races and management of cattle and sheep are dealt with and how such may most profitably be fed and fattened for the market.

There are numerous tables showing the materials consumed by stock at various stages of growth and under varying conditions. Other tables show the food, increase, manure, &c., of fattening animals, as well as showing the average composition of various kinds of food and the comparative value of each.

We congratulate Mr. Wrightson, who was formerly Professor of Agriculture at the Royal Agricultural College, Cirencester, and now of the North Wiltshire Agricultural College, and hope before long to see the advanced text book of the same series giving us more detailed information.

FARMING WITHOUT MANURE.

To the Editor of the "North British Agriculturist."

SIR,—I keep no live stock, nor shall I. I can always buy what manure I require; but I am an advanced cultivator, and hold what to some would appear to be strange notions. In the early ages of the world, plants had to grow without manure. The plants had to grow first from the bare rock, and animals had to feed on the plants before there was any manure. Now we have the accumulated deposit of ages, which only requires cultivation to supply the elements of nutrition that a plant requires. Hence on good soil *cultivation is an equivalent for manure.* Thoroughly good soil allows a free passage for the circulation of the air. The gases of the air act and react on the soil, or supply food direct to the roots and leaves, so that every time we stir the soil it gathers a supply of riches from the air (heaven). The gases of the air, you at once see, are inexhaustible; so are the locked-up treasures of good soil. It only needs disintegration and pulverization to yield food for 100 or even 1,000 crops. Thus on a piece of such land put into cultivation I would grow a crop of wheat year by year of four or five quarters, which might be sold at 40s per quarter, and still have a profit after *all* the expenses of cultivation are paid for, without any manure at all, simply depending upon cultivation.

The ordinary practice of farmers, and even gardeners, is to hoe land only to kill the weeds. An advanced cultivator would hoe or dig it over, even if there were no weeds, for the purpose of aerating the soil, and allowing free circulation to the gases from the air. Soil worked in this way (good soil I am speaking of) is in a great measure self-supporting for moisture and also for gases of the plant, which can be absorbed by the roots. I have been an experimenter for the last twenty years with soils, manures, and plants, and have learned from failure as well as success. I have a technical knowledge, and call myself a *specialist*, and, when I plant my plants, I see the future of my plants traced out clearly, and doubt and uncertainty are reduced to a minimum. Such a thing as a failure of a crop of fruit from strawberry plants never enters into my mind. 'Work is prayer' was the motto of the monks of old, when they cultivated their land; so it is with me. Work is prayer, and cultivation manure, are the two leading principles of my life, and I place me on a higher level than most cultivators have attained to. The blessing of health (and perfect health induces strength) which I fully enjoy enables me to put these principles into practice. The perfect man possesses the strong muscles and the clear brain; and if in addition he is cheered and strengthened with the thought that his work will benefit his fellow-men, and be rewarded with the approval of his Creator, he need wish for no higher or happier state in this life.

Nothing is easier than to produce disease in plants by feeding them with gross manure, especially if of a stimulating nature or in a liquid state. Feasting plants brings on disease and predisposes to disease. As with animals, so with man; and when I say that men might live to 100 years or more, I argue in this wise: men live to 80 who have spent their lives feasting and fasting, drinking spirits and smoking tobacco, breathing impure air (in bedrooms at night especially), and drinking polluted water, the pores of the skin clogged with the accumulated deposit of years, besides other excesses. In spite of all this living in defiance of the laws of life, men live to 80 or 90; yet is it any wonder that man is subject to disease? No; the wonder is that he does not suffer more. If, after abusing and wasting life, as is the too common practice, disease did not make its appearance, I should be inclined to doubt the truth of that wise law of nature which ordains that punishment shall follow breach of law.—I am, &c

W. L.

[We should say, regarding the above, which has been sent to us by our Aberdeen correspondent, that shallow egotism is apparent in every line. The good effects of turning over the soil, so as to lay it open to the action of the air, are universally acknowledged; but it is equally understood that the fertilizing qualities of the richest soil will become exhausted by constant cropping. If the land gets neither rest nor manure, it will simply, after a period more or less prolonged, according to the nature of its constituents, cease to yield crops.—ED.]

KITTUL FIBRE.

(From "Notes on New Industries." By ARTHUR ROBOTTOM.)

[This article appears in the *Labour News*, a copy of which has been sent to us. Our readers will observe that its very excellence has been fatal to the kittul fibre, the brush and broom makers considering it had for trade to use an article which is everlasting! Surely there are other important purposes for which this quality would render it valuable?—ED.]

About 30 years ago the fibre now known as kittul was unknown in England. It came under my notice in a somewhat curious and accidental manner. At this time I was frequently in London, and, being a lover of music, I spent my evenings at Julien's concerts. At the back of the orchestra, I observed a table, covered with a large number of foreign papers. One evening I walked to the table and took up a paper accidently, which turned out to be a Ceylon journal. Being interested in the fibre trade, my eye at once turned to a paragraph containing a short account of the kittul palm. I was so much struck with the merits of the palm, as set forth in the article, that I at once put myself in communication with a Ceylon firm, requesting them to forward me a small parcel to London. In due course the sample of kittul fibre arrived, and I began to introduce it to the brush makers as a substitute for bristles. Shortly afterwards other parties began to ship this fibre, and a very large parcel arrived—just as it was gathered from the trees, and quite useless in this state to the brush-makers. This was put up to auction, and I bought it at 1d per lb., considerably less than the cost of freight and other charges. There were some tons of it, and I had it stored in some coach-houses and stables at the back of my house in the suburbs of Birmingham. Some weeks afterwards, I was making some experiments with a new kind of oil, and wishing to cleanse a large saucepan that the oil had been in, I took up a small bundle of this kittul (the colour of which was a dirty brown) and began wiping out the oily saucepan. To my surprize I found that the moment the fibre came in contact with the oil, it turned to a beautiful black. I imparted this information to a practical working man, who was a friend of mine, and he at once became interested, found his experiments successful, and went into the concern vigorously. Before long the trade increased to a very considerable extent, large quantities being used by the brush-makers to improve the quality of the bristle broom.

Thus the trade was regularly started, and bade fair to monopolize a large share of the attention of the brush-makers of the United Kingdom. An extensive use was found for kittul in the making of

brushes for polishing thread; but before long science stepped in and a patent roller superseded the kittul brush. Meanwhile the brush makers employed this fibre to mix with other well-known but cheaper fibres in the manufacture of their brushes, but from the first hesitated to make the brush *alone* with kittul. The trade, however, has now visibly declined, and at the present moment there are large quantities of this useful fibre in England unsaleable, except at an enormous loss to the shipper; and bankers, merchants, and brokers are pressing the sale, with a view of realization, for the purpose of recouping themselves for their advances. That this should be the case may seem surprizing, when it is known that kittul is the *best substitute yet discovred for bristle*; but the public will probably be more surprized to hear the reason of the decline in the trade. The brush-makers became frightened: they discovered, in course of time, that kittul would *never wear out*, or virtually this might be said of it, so extraordinary are its properties of standing wear and tear. Then arose the cry that the trade would be "spoiled." The resolute few have had to give way before these tradesmen who by increase of numbers have ruled the market, the success of the latter being mainly due to the ignorance and consequent indifference of the general public. I have tried in vain to induce the brush-makers to use kittul for making the brooms ordinarily used for sweeping floors, shops, offices, mills, railway platforms, and indeed all places where hair or bristle brooms are used, but up to the present the cry "it will spoil the trade" has nullified all my efforts. The Government, and all other consumers, would effect a very considerable saving by using brushes only made of kittul. I have placed these facts before them, and personally I am not at all despondent upon the issue. I have lived long enough to see many infants pass through terrible vicissitudes of infantile maladies, yet in the end weather them all and grow up stout and hearty men and women; and in the same way I have little doubt that when once the kittul fibre has passed through this gate of opposition raised against it by the brush-makers, and the public are fairly alive to the value of this product, the trade will thrive with a yearly increasing vigour, and so create employment in this at present almost unworked and unlimited branch of industry.

The manufacture of kittul brushes will demand a somewhat higher class of labour than that required in the manufacture of the Piassava brooms, and will consequently secure higher wages. In all new industries the transition period will involve some difficulty. But as soon as some enterprising employer turns his attention to this trade, and is willing to manufacture brooms from the kittul fibre, a much extended business may be looked for. As a sample of what may be done, I induced a manufacturer when in Buffalo to try a sample of one cwt., and he has been successful in bringing it into general use on a large scale in that part of the United States. At Messrs. Bright's works at Rochdale, the kittul fibre has been for some time in use with remarkable success. An ingenious person in connection with the works insisted on having the brushes used for sweeping up the heavy dirt that collects on the floors fitted in the centre with kittul fibre, while the outer portion of the broom remained as before of bristle. Though Messrs. Bright are in all probability ignorant of the name and quality of the kittul fibre, as the brush-makers fairly conceal the name, they are fully alive to its superiority and resolutely refuse to use other brooms than those just described. When in Constantinople, I observed in one of the bazaars a small portion of English-prepared kittul, and on enquiry I learned that it had been sold to go into Persia, but I was unable to arrive at the use it was intended to be put to.

The kittul brushes that are made in this country are known by the name of "elephant-fibre" brushes. The origin of this name lies in the fact that in Ceylon the wild elephants are secured with kittul rope. This brush wears much longer than bristles and can be had at half the price.

The kittul palm or Bynee (*Caryota urens*) is something like the Piassava palm and grows in the south of Ceylon—it is found nowhere else. In that country the fibre is largely used for fishing lines, and in England it is sometimes called "India gut."

AGRICULTURAL EXPERIMENTS IN CENTRAL INDIA.

To the Government of India we are indebted for copies of correspondence respecting certain experiments with new products in the Division of Chhattisgarh.

We quote as follows from the remarks of the Chief Commissioner:—

An increased supply of forage is an object of great importance. On it depend in a large measure the improvement and maintenance in health of the cattle supply of the country. In the Chhattisgarh Division the mortality from cattle disease is annually very great, and much of this mortality is believed to be of a preventible character. If cattle were better fed, better housed and more carefully tended in health and disease, fewer would die.

Experiments were made with:—(1) Kharif jowari, (2) Rabi or ringni jowari, (3) Reana luxurians, (4) Rain-tree (Pithecolobium saman), (5) Lucerne, and (6) Mangel Wurzel.

The result of the experiments may be summed up as follows:—The kharif jowari failed; the rabi or ringni jowari appears to have been confined to the Sarangarh State, where the yield obtained was extraordinarily good: the attempts to acclimatize the reana luxurians and the rain-tree promise well; Lucerne thrives, but cannot, you think, compare with the reana luxurians; while, as regards Mangel Wurzel, no definite opinion can yet be formed in respect to the suitability of the soil and climate of Chhattisgarh to its cultivation.

In regard to fodder crops, the experience gained in the North-Western Provinces seems to establish that the ordinary cultivator will prefer the ordinary jowar to any exotic staple; the former will give him a food as well as a fodder crop, while the latter will only give him a fodder crop.

In reviewing the experiments conducted at the Cawnpore Experimental Farm during the autumn of 1880, the Secretary to the Government of India in the Home, Revenue and Agricultural Department remarked:—

"To judge from the results of the comparative cultivation of exotic and indigenous fodder crops, the common country jowar is practically equal in value to the black seeded sorgho and greatly superior to reana luxurians. Guinea grass seems to be a more promising crop than the other exotics tested, and its further cultivation will be watched with interest."

As guinea grass does not appear to have been cultivated in your Division during the year, it may be of use to quote the mention of it made by Mr. Fuller of the North-Western Provinces, in the report on the Cawnpore Experimental Farm for the Kharif season 1880:—

"Guinea grass gave an outturn, which was a little larger than that of juar; but independently of this, it appears in many respects to be a crop eminently suited to meet some of the requirements of Indian farming. In the first place, it is a perennial, so that when once planted out the only expense it entails, in order to yield two good cuttings a year, is an occasional dressing of manure and occasional irrigation. The crop

from which the experimental cutting was made had been cut previously in the month preceding, but no manure had been given it since July 1879. It was also very scantily irrigated, the only waterings being one in May (after the first cutting), and one ten days before the experimental cutting was made, that is to say the crop kept green during the hot months from April to July, with only one watering, and was but little affected by the failure of rain in July and August. It may be safely said that no other fodder crop now known in India could have done this, nor in all probability could the guinea grass in *its first year*. But in the second year its roots naturally become far stronger and larger than the roots of any annual grass can ever be, and are therefore able to seek the moisture they require at a greater depth in the ground. Hence guinea grass in its second year may be considered a deep feeding crop, the only one now known in India, and as such it is more able to resist drought than any other of the fodders cultivated. It appears specially well suited for planting along the banks of canal distributaries, streams or ponds, where its roots will be able to obtain moisture for themselves without requiring surface irrigation. It may be mentioned that on account of these advantages, Mr. Buck made several attempts to obtain a consignment of seeds from Messrs. Suttons and other seedsmen, but failed, since it does not appear to be recognized in England by the name it bears in India, and there seems to be a like confusion as regards its scientific name. A consignment has, however, now been promised, and a quantity of seed has been raised in the farm for distribution during the ensuing year."

From the report of the Commissioner of the Chhattisgarh Division, we extract a few passages :—

The main difficulty in the way of increasing the supply of cultivated forage has hitherto been the indifference which the ryots of Chhattisgarh and Sambalpur evinced in regard to feeding their cattle. But the great mortality which has taken place among their herds during the last two years has opened their eyes in some degree to the folly of leaving their animals to die from neglect and semi-starvation ; and during last cold weather wherever I went I found both malguzars and ryots ready to appreciate, in theory, the importance of properly feeding their plough cattle. I think then we have reason to hope that the practice of cultivating forage may gradually make its way in this Division, and some trouble and time may well be given by executive officers to working for this result, for its effect on the agricultural prosperity of the country will be great.

A manure which shall be both abundant and cheap is greatly needed in Chhattisgarh, where so large a proportion of the droppings of cattle are consumed as fuel, and it seems not improbable that bone dust may supply this need to an appreciable extent, for bones are fairly plentiful, and they can be ground into powder with the ordinary lever mill at small cost. With regard to the value of bone dust as a fertilizing substance, Mr. Buck remarks in his agricultural report for 1879 :—

"The high cost of bone superphosphate in this country must place it beyond the reach of the ordinary cultivator, but bone dust, that is to say bones powdered fine, but not treated with sulphuric acid, is within the reach of every body, and though more tardy in its results than the superphosphate (being less soluble) will give in the end almost as satisfactory results."

THE DATE COFFEE COMPANY LIMITED.

TO THE EDITOR OF THE "TIMES OF INDIA."

SIR,—I shall be obliged by your correcting an inaccuracy in an article in your paper of the 26th ult. referring to this company. The works have been in operation here more than eighteen months during which time we have been supplying the principal towns in India with our coffee, including Bombay. The dates are *not reduced to a cinder*, but only sufficiently roasted to admit of grinding, and are then mixed with one-fourth of Mocha to three-fourths of date.

I may add that you have advertized our coffee in your paper, and that our agents are Messrs. Morenas & Co., Medows Street, Fort, Bombay, who have always a stock on hand. E. J. EARDLEY MARE,

Manager, Date Coffee Co. Ld.

Kurrachee, Napier Road, May 2.

[But, as the result of Mr. Gladstone's resolutions, Mr. E. J. Eardley Mare will find the occupation of his Company gone as far as importation of their stuff into the United Kingdom is concerned. If the Company called their commodity date dust or powder, all would be right, but dishonesty is involved in the term "Date Coffee.—ED.]

THE NEDDIWATTUM PUBESCENS SEED, offered for sale by public auction by Mr. Symons yesterday, (June 4th) realized an average price of R2 19 per oz.

KAPOK.—The attention of shippers in Ceylon was first directed to this cotton as an article of export by the remarks of the Ceylon Commissioner to the Melbourne International Exhibition. Kapok or silk cotton has recently been shipped to Australia from Galle, per P. & O. steamer, and it is to be hoped that ere long a lucrative trade may be established.—*Cor.*

DAMAGED COFFEE BEANS FROM BADULLA.—With reference to the damaged coffee beans in parchment, which we noticed a few days ago, a quantity of punctured cherries has been sent to us, and the idea of damage by hail suggested. But our entomological referee writes :—

"The damaged cherries have been carefully examined. The wounds are deep, penetrating the parchment and injuring the bean more or less. Some have become quite withered and blackened. The mischief appears to have been done by some insect, perhaps by the bug *strachia geometrica*, described at page 13 of Nietner's 'Coffee Tree and its Enemies.' The insect should be searched for by the sender of the damaged berries."

COFFEE CULTIVATION IN PERAK.—"It is satisfactory," says the *Penang Gazette* of 22nd April, "to hear from Perak that the prospects of coffee are looking up, and the extraordinary results so far, of the labours of the pioneer planters, are encouraging to an unexpected degree. Liberian seedlings, only ten months planted out in the field, bloomed twice in February on some estates, and, what is more important, the blossom has set well, and so extraordinary has been the growth that some of the trees have attained the height of five feet within the above short period. In the district where these results have been obtained (that of Slim) there appears to be one well-defined season at all events. This of course does away with the objection so frequently urged, that, owing to the want of periods wherein trees might lay back at rest after delivering a large crop, they would be exhausted, unless manured to an extent which would almost cover any profit that might be obtained This theory was based on the fact that coffee trees in the plains in the Straits show blossoms and berries in all stages at the same time throughout the year. We are referring to the Arabica species, none other being known in these parts till within the last year or two. But the Liberian species is a much hardier plant, and may be able to stand the brunt of such a drain on its resources."

Correspondence.

To the Editor of the Ceylon Observer.

NEWS FROM FAR FIJI:—COFFEE AND *HEMILEIA VASTATRIX*, TEA, CINCHONA, SUGAR, LABOUR, &c.

Fiji, April 1882.

DEAR SIRS,—It is some time since I dropped you a line from this utmost corner of the earth, and I don't often see any remark in your valuable paper concerning this latest addition to England's colonies.

Of course, you have heard that all the experiments conducted on the great Amalgam estate for the eradication of *H. vastatrix*, and a list of which I sent you long ago, describing what was done, proved ineffectual in spite of every care taken, and that Mr. Parr, the owner, has sued Government for £20,000 damages, on the grounds that the estate was ruined by them during their occupation. The case has been tried, but the Chief Justice has not, as yet, given his decision; so I cannot well comment on it. One thing I am certain of after all our experiments, and that is that lime and sulphur will not cure *H. vastatrix*. The mixture may mitigate the disease for a short time, and may do good, if constantly applied, but I much doubt if the extra expense incurred would be recouped by larger crops. After what I have seen I should not dream of applying any more. I have a great deal more faith in hyposulphite of soda and carbolic acid, and I fancy an antidote to our enemy will be found in one or the other.

A friend of mine, Mr. Storck, who resides on the Rewa, declares most emphatically that he has discovered a certain cure. Of course after repeated failures here, as well as in Ceylon (the experiments in the latter colony being conducted by scientific men), one is very chary of believing in certain cures. Nevertheless, Mr. Storck has given me permission to use, and is anxious that I should try, his system of vaporization for the extinction of leaf-disease, and, after what I have read in his letter to me describing the system to be adopted, I feel inclined to give it a fair trial, over, say, 20 acres, and to see if it will turn out, as he says, a perfect and lasting cure. Should such be the case, of course the enormous benefit that will be conferred on all coffee planters where *H. V.* exists cannot be overestimated, and Mr. Storck will certainly deserve to make a pile. His system, as far as I can see, will not be a costly one, and the expense, after first outlay, will be but small. I cannot give you particulars, as Mr. Storck has not given me permission to do so, but, should I try the experiment, as I hope to do shortly, I do not suppose there will be any objections to my making the results public. In that case you shall know what I think of it.

Hemileia vastatrix has commenced again just here (Taviuni), but the attacks do not seem to affect the trees so much as they do in Ceylon, owing, I suppose, to our richer soil. The young coffee 2½ to 3 years old is giving a heavy maiden crop at an elevation of about 400 feet above sea-level at the north end of this island: above that elevation the crop is not so good on coffee the same age at the same end, but, strange to say, about eleven miles down towards the south end, coffee of the same age and at an elevation of nearly 1,000 feet is giving about 4 cwt. to the acre, whereas at the north it may be put down at half, shewing how the weather varies at the different places. I have often known it raining day after day up here (1,000 ft. above sea-level), when they have hardly had a drop below, and again raining away here, when it has been very dry weather indeed at the other end!

All the estates I have seen look very promising indeed, for the everlasting "next year," and, should we have dry weather, we shall get bumpers and no mistake, *if* hurricanes only leave us alone. We have just passed the hurricane months, and we escaped I may say, almost scathless this year. We had a blow at the beginning of January, but it did but very little damage indeed; hardly worth mentioning, in fact. They had a flood on the Rewa, in Viti Levu, where most of the sugar-planting is going on, but only one or two planters seem to have been serious losers—one especially, who had a large acreage of cane under water for a long time which was utterly destroyed, and whose losses are put down at £3,000. I had a letter from a friend, planting coffee on the Rewa, the other day, but he does not complain of the ill effects of the blow, although his place must, I think, have felt it.

A Mr. Wilson is putting up a coffee-curing establishment at Wairiki in Taviuni, which ought to be a boon to the planters there, if he gets out a man who understands the work to superintend the curing. There is more coffee I should say planted in Taviuni than the other parts of the group put together, and yet our acreage is but small: less than 1,500 acres.

TEA.—I have planted up about thirty acres with Assam hybrid and want to plant up another forty acres. The young plants are growing well, and look promising. I sincerely trust the cultivation will prove successful. I see no reason why it should not, as we have such good soil, rainfall well distributed, and favorable temperature. I notice a good many of the plants tending towards constantly seeding, which is a drawback some of you have had to contend against. This, I expect, is owing to the seed not being the right kind exactly. Some plants, on the other hand, have fine large leaves, and do not show seeding inclinations so much, and it is off these, I fancy, seed for nursery purposes ought to be gathered. Our oldest plants, stock ones, are nearly 4 years old from the time the seed was planted; our next 1 year old, and so on down to some just planted out. I have planted both at stake and with nursery plants. I prefer the latter plan provided the plants are not too large.

CINCHONA.—I have made nurseries of both condaminea and succirubra. Some of the former after germinating died off, and part were destroyed by some insect or other during the night. The latter is growing well in the nurseries, but when planted out does not grow so rapidly, or look so well, as plants in Ceylon of a similar age. I am disappointed with these results, as I was in hopes that succirubra would have turned out a success at an elevation of 1,000 feet and upwards in Fiji, but, judging from what I have seen here, succirubra will not do at 1,000 *well*.

SUGAR.—This is the industry attracting most attention at present, and which I expect will turn out to be the staple product of the colony. Several mills have lately been erected, and more will soon be put up in different portions of the group. At present Rewa (a river in Viti Levu) is the place were most of the sugar-planting is done, and where the colonial sugar-refining company have erected a very large mill. Mr. Lee (late of Ceylon) has also a large mill and is growing cane on his own account as well as crushing that of others. It is strange that Ceylon men, who have been coffee-planting, should leave their old love and go in for something new out here; but such seems the case. There is Mr. Hodges in Taviuni going in most extensively for sugar. He has already a lot of land under cane, and by the end of this year will probably increase it by 600 to 800 acres. His mill, a 10 ton one, is expected this or next month. Then again there is Mr. Akers, who has just bought nearly 2,400 acres in Vanua Levu, and who intends to plant cane: so you see three of them have changed over. Ten shillings is the general price paid per ton for

cane delivered on the river banks. Lots of varieties are planted. Planters expect to cut 30 tons of cane per acre on an average. They may do this for a few years, say three to five, but, I very much doubt if they will keep it up without manuring. I enclose some meteorological returns. I am keeping a return of the rainfall &c., here, but, as it is only nine months since I commenced, I cannot send you complete returns till later on.

LABOUR.—Our supply is causing anxiety to the planters. Owing to the strict Government regulations a very few, if any, vessels are offering to go recruiting this season, and everyone seems to be afraid of their labour force falling exceedingly short, as a lot of men are being paid off without a chance of their being made up again. Some of the planters are trying to get men through their agents, one of whom has been to the colonies to try and charter vessels. Of course, it is impossible to say what the cost will be in the latter case, but it may be taken for granted, I think, it will not be less than £16 per head, the cost estimated by Government some months ago. Does it not seem absurd that we should have to go to the New Hebrides and Solomon Islands for labourers costing £16 and more per head, and even to Calcutta for coolies for whom we shall have to pay £22 or more, when we have a native population here of upwards of 100,000? and I suppose 10,000 is more than the number of laborers required at present by all the planters! One would naturally think that, in a new colony where there are but a few planters, and which has a population like this one, labour would be exceedingly plentiful and cheap; but such is not the case: the price of labour is steadily increasing annually, and there is no saying where it will stop. When I first came out nearly 4 years ago, Polynesians cost £9 per head to introduce; now the estimate is £16, for which sum it is doubtful whether we shall get them. The wages of the men have not risen—£3 each for able-bodied people—but I expect they soon will.

FIJIANS.—The few that work, or are allowed freely to engage, get more than they used to, and the cost of recruiting has increased in proportion, say 20 to 25 per cent more than four years ago. Coolies get 1s per working day, and the planters have to pay introduction expenses estimated at £22 per head. This sum must be guaranteed when you send in your application for men, and must be paid up when they are allotted. Formerly we did not guarantee, and £15 was the sum fixed by the ordinance to be paid in 5 annual instalments, but, owing to the home Government not sanctioning a loan, a new system has been inaugurated. The coolies are causing a lot of trouble wherever they happen to be. The great thing they object to is task-work, saying no mention was made about it when they were recruited, and that on their agreement it is stated that for 9 hours' work they are to get 1s. My coolies have struck work and refuse to go to any task-work whatever, although in our ordinance of course task is mentioned. The consequence has been that all of them have been sent to gaol. About 35 were liberated the other day, but still refused and were again imprisoned. The men seem determined on their point, and how the question is to be finally settled remains to be seen. They do not mind imprisonment at all; so all say. As a lot more coolies are shortly expected, the sooner this question is settled the better. If it is not finally settled, before the new lot arrives, the example set by these will be so bad that we may fully expect all those arriving to follow suit and strike against task-work. Hindustani coolies are difficult fellows to manage, and I would not recommend anyone who is not up to their ways to engage them. They are not nearly so tractable as Polynesians. The great objection to the coolies is that they are so fearfully litigious, which does not pay out here, where you are fined for the least assault or infringement of any of the numerous labour ordinances. If you smack a cooly on the cheek, he will run down to the magistrate and lay a complaint as sure as fate, and then you may make up your mind to pay from 10s upwards, according to the severity of the assault or number of convictions against you previously. The Agent-General of Immigration has the power of removing all your labour, if you have been convicted more than three times. It makes it very difficult to manage a large body of men, when trivial assaults are made so much of and the labourer sees his master fined and cautioned. Personally I am much against striking any labourer, but still there are occasions, when a man is insolent, extremely lazy, &c., when it is absolutely necessary for example's sake to give him two or three cuts with a small stick or cane. When occasions like these occur, a certain amount of discretion ought to be allowed to the magistrate to act apart from the ordinance. For instance, a planter is summoned, we will say, for his first assault by one of his men, who has been very insolent, and who was punished for his insolence by having three or four cuts across his shoulders with a cane. Under the above circumstances, I maintain that a caution to both would have the desired effect, without punishing the superintendent by fining him and allowing his labourer to go back, crowing over what he has succeeded in doing and setting a bad example to all the others. One may say on the other side: "True, but why take the law into your own hands, when you know you could get the man punished by imprisonment for insolence?" This is doubtless correct, but still the effect would not be nearly so good as a few cuts administered promptly, when the man was first insolent, letting alone the bad feeling created by taking your labourer to court.

My scrawl has reached a greater length than I intended. So I shall conclude now by wishing Ceylon better crops than last year.—Yours truly,

A. J. S.

CINCHONA ANALYSES.

16th May 1882

SIR,—Permit me to suggest through your columns that advertizers of seed from "parent" trees should be a little more liberal in their information. It certainly seems very essential that, when the analysis has been derived from one selected tree, and, perhaps, from *renewed* shavings from that tree, such information should be in the advertisement, or what are intending purchasers to think? If nothing is said about age of trees, renewed bark, or renewed (first, second or third) shavings, one cannot but believe that the analysis given refers to *original bark*! What we want therefore is *more information* on these very essential points. I am afraid purchasers of seed are too often *misled* by ONE-SIDED STATEMENTS.

INDIA TEA IN COMPETITION WITH CHINA AND CEYLON TEA IN THE BAZAARS IN LIEU OF THE EXTINCT COFFEE.

DEAR SIR,—The following quotation from an article in the *Westminster Review* on "the Fair Trade movement" may be of interest to your readers. The reviewer, noticing that part of the Fair Trade programme which proposes that tea from India or other parts of our empire should be imported free, a duty of one penny per lb. being continued on Chinese and other foreign teas, continues:—"Hitherto the tea planters of India have had to face the competition on equal terms of the old established tea-growers of China, and they have been forced to do all in their power to improv

the quality of their tea. This they have done with such success that Indian tea is now recognized as the best in the London market, and the importation of Indian tea has largely increased, while that of Chinese is almost stationary."

I do not know whether it has occurred to Ceylon tea-growers that a very large market is open to them for the disposal of the cheaper kinds of tea in the native bazaars. I am told that the native coffee-gardens, from which the people have been throughout the island supplied with the matutinal cup of coffee, are all but extinct. Would it not be possible to replace the cup of coffee by a cup of tea, if low-priced teas made up into quarter lb. packets with showy paper coverings were introduced into the "kadeis"?

I know of one not inconsiderable station in Ceylon at which the only tea procurable was akin to senna by reason of its mustiness and nastiness, and the price was R4 per lb.—Yours truly, T.

[The "Fair Trade" idea of free tea from India and the colonies, with a protective duty of 1d. per lb. on China tea, is, of course, too absurd to be seriously considered. The tea duty is simply a revenue impost, and if the tax is lowered, or, what is not unlikely at an early date, abolished, all tea will be treated equally. Attempts in India to supply native bazaars with tea have not been very successful, but if planters could dispose of their larger and broken leaf and their dust tea on the spot, it would be very desirable. But native dealers must buy from the planters and manage the sale.—ED.]

TO KEEP BUFFALOES OUT OF A CLEARING.

DEAR SIR,—What would be the best thing to plant under a wooden rail fence, which would grow into a thick hedge sufficient to keep out buffaloes, by the time the fence had fallen to pieces (say in 2½ years)—elevation 2,400 feet? LEDGERIANA.

[The green aloe, *Fourcroya gigantea*, would probably fulfil the conditions desiderated. Sapan, being a thorny plant, makes a hedge which, if planted close enough, would resist even buffaloes, but we doubt if it would make sufficient growth in two years. But planters, (few we suspect) who have tried hedges may be able to give a more definite reply. A sunk dyke, if of sufficient size, would be the most effectual guard, but it would be very expensive.—ED.]

SUCCESS OF NEW PRODUCTS IN CEYLON.

Dumbara, 27th May 1882.

DEAR SIR,—Some time ago I saw a letter in your paper saying that Liberian coffee did not grow well from stumps. I now beg to inform the writer that I have been very successful with Liberian stumps—in fact, they are a great success, not twelve months old, and a finer clearing you could not see, requiring no shade, and growing rapidly.

The Liberian coffee is very much fonder of throwing out suckers near the roots than C. Arabica. This any one can see, and knows, who has anything to do with the new variety.

Fine weather again after the short burst of the S. W. monsoon. All new products are doing well in this district, cocoa, and Liberian bearing at a tremendous rate, when we have aged trees. No doubt there is a great fortune for new products in the lowcountry of Ceylon yet.

If a reaction would only set in, and capital flow into the country, we would go ahead at a pace which would astonish you. They say when things get to the worst they must mend, but they are long in mending this time.—Yours faithfully, NEW PRODUCTS.

LEAF-DISEASE OR UNPROPITIOUS RAINFALL I.S. SHORT COFFEE CROPS IN CEYLON.

28th May 1882.

SIR,—I have just received your supplement, "Public Works Department Return of Rainfall during 1881," and I find that, in December of last year, the figures relating to the coffee districts in the Central Province are far away in excess of the figures given representing "mean during 10 years."

Well, we should probably not have suffered from having double, or, as has been the case in some of the Kandy districts, even *treble* the amount of rain usually apportioned to December, if that month had been followed by something like an average rainfall for January, February and March. I believe, however, that it is a fact we were overwhelmed in these months, and if you find such to have been the case (I have not the figures to refer to), small wonder, say if the blossoming season this year, on the Kandy side, should have proved such a disastrous one to proprietors. Yet we are told by the editor, "C. Times," tat the weather was "simply splendid"! Perhaps you will be able to throw some light upon this question—either by the P. W. D. returns, or by those of the Surveyor-General, say, for the months, indicated, comparing them with the mean of previous 10 years for December, and of 11 years for January February and March.

Looking at the returns for the N. W. Province, I see Kurunegala is credited with a rainfall in December last of no less than 40·15 inches against for that month a mean during 10 years of 6·05!

In the Central Province, Dikoya would appear to be an exception, having had apparently only an average rainfall in December, say, 10·70, against a mean of 9·13 for 10 years!—Yours. DELUGE?

OPERATIONS OF THE CALCUTTA TEA SYNDICATE: AMERICAN TEA.

CALCUTTA, 10th March.—Since the issue of the circular of the 26th January, the Committee of the tea syndicate have received some valuable information from New York, which they think will be of use in guiding shippers with reference to the preparation of their teas for the American market.

You are probably aware that, in the opinion of the Committee and the members generally, our Indian black teas should stand upon their own intrinsic merits, and that it would hardly be an advisable policy to manufacture a special class of tea for a particular market. On the other hand, our friends in America strongly advocate the shipment of some parcels of green tea, and their views on this point are worthy of consideration.

In a letter dated 9th January 1882, from Messrs. John C. Phillips & Co., of New York, to Messrs. Whitney Brothers & Co, of Calcutta, an extract from which has been kindly sent to the Committee, they write:—"We note that you find very little disposition among planters to make green teas, but we trust you will not relax your efforts in this direction, for from even a small beginning of 10, 15, or 25 packages, which could not give any of them much trouble, great results might come in time. It would not prevent our work at the same time upon the black teas, and we take it planters would not be sorry to find a demand for the green if not for the black. We have sent to Mr. Mager complete samples of green teas lately sold here from only an average class in quality, with prices obtained for each line, and we feel confident that the value will in many lines show a good margin for profit, if made from Indian teas."

The samples of green teas referred to above have not yet come to hand, but a valuation report upon them will be circulated in due course.

With regard to black teas for the American market, Mr. Sibthorp writes on the 13th January :—

"A black leaf tea with a flavoury liquor, like a good Kangra Valley Pekoe Souchong, will sell most readily here. *Tippy teas are not cared for, the tips being looked on as more or less a drawback to the appearance.* The leaf should be small and even, assimilating as nearly as possible to a China congou, to be easy of sale. Rough souchong teas and broken leaves are very hard to deal with, and reddish looking or mixed teas are also difficult of sale. Time and knowledge of our teas will, no doubt, overcome many of these prejudices, but at present they are very strong."

A telegram dated 24th ultimo from this gentleman, at New York, has been received as follows :— "Good auction 250 packages. Can sell equal quantity weekly till July."

This is very satisfactory as a commencement of operations in that Market, and as the total shipments of the Syndicate to New York amount to 3,299 packages, there is about a three months' supply for our agents to deal with.

Mr. Sibthorp's report upon the tea trade of the United States and Canada has no doubt been read with interest, but the Committee think it well to draw your special attention to his remarks upon the style of package most likely to prove attractive to buyers. "Before I close, one thing I would like to impress strongly on those who take an interest in working up these foreign markets is that the present style of packing considerably retards the sale of Indian teas. *Large packages are unsaleable, except at a considerably reduced price: half chests containing 38 to 5 lbs. nett will sell most rapidly.* They should be neatly finished and marked, so that, instead of being, as they are considered here, an eye-sore in the retail dealer's shop, they would prove an attractive ornament. There is a stronger feeling here against rough packing (of any kind of goods) than I can give you any idea of. A retail dealer will not purchase a rough package, as he calculates it would be likely to keep customers out of his 'store.' One reason I think why the Japanese have got such a strong hold on these markets is the remarkably neat way in which their packages are made up; they are neatly matted and papered with a stylish label, setting forth the class they claim to contain. I cannot see why we should not vie with the Japanese in this, and that the trouble taken would be well repaid I have not the slightest doubt." The size of the chest should be the same as that recommended for Australia, *viz.*, 1'. 5" × 1'. 5" × 1'. 3".

The Committee would also draw particular attention to the style of tea most in favor, as reported above by Mr. Sibthorp. It is possible that other grades may be found saleable, as our teas become better known in the American market, but it is impossible to express any more decided opinion on this point at present, and it is only by judiciously trying the market that we can ascertain the probabilities of other classes attracting buyers, as they have done in Australia.

The advices which have lately been received from New York show that most grades of Indian black teas have met with a favourable reception in that market. The exception is broken tea, for which there appears at present to be little or no demand, but our agents think that this may be developed in time, as has been the case in Melbourne. They write very strongly as to the desirability of keeping the New York market supplied with our good liquoring blak teas during the next few months, when the scarcity of China congous must increase, so that the dealers may look to Indian teas for their supply of early fine teas next season instead of to China teas, as hitherto.

MOCHA COFFEE, while still considered the most delicately flavored, has the merit of being the parent stock from which all other coffees, except Liberian and some other African and a few East India sorts, have sprung, its superiority being in all probability due to the excellent soil and even climate of that part of Arabia.*—*Merchants' Review.*

PLANTING IN BURMAH.—The local Government is trying to induce people to take up waste lands in the Tavoy district for planting coffee, tea, cinchona and spices. The terms on which these grants will be given are advertized in the *Rangoon Gazette*, and they are sufficiently liberal to attract settlers, except perhaps that the Government reserve all minerals and metals under and within the lands granted. It would be better, I think, to allow the grantee to get any metals, or minerals which he was fortunate enough to find, on payment of a royalty. In the recent cases for compensation on account of land taken up for the Kokhine water-works, the Government wished to assert that even brick-making was not allowed on land they had granted freehold for ever, and, under the conditions advertized, planters would, perhaps, find that they were infringing the rules, if they made bricks out of the clay on their grants for their own dwellings. As regards payment of revenue, the terms are liberal, ten years being given rent free, provided *bonâ fide* steps to cultivate a reasonable proportion of the land are taken by the grantee. The lands are said to be at altitudes varying from 100 to 6,800 feet above the sea, with a rainfall of from 190 to 220 inches a year. Government will further pay to the first four grantees who begin *bonâ fide* planting operations R15 per head for every Indian or Chinese cooly, male or female, over 16 years of age, who may be settled or housed on their plantations before the 1st March 1885.—*Friend of India.*

TEA.—At a recent meeting of the Society of Arts, a discussion took place as to the relative cost of producing a pound of tea in China and in India. We are not in a position to speak of the cost in China, but we think that there is more recent data fo fixing the cost in India than the figures of 1879. According to the general opinion of the meeting, the average cost in China was 5¾d., while in India and Ceylon it was 10¾d., the extremes of figures presented to the meeting running from 4¾d. to 1s. 4d., the average of China and India taken together being fixed at about 6¾d. As we said before, we do not feel competent to challenge the figures for China, but we believe those for India are very near the truth, always, be it remembered, for 1879. If an enquiry were made into the present cost of manufacturing a pound of tea, we think it would be found to be about six annas, all charges included, up to the time when the tea leaves the factory. A further charge of two annas lands it in the London warehouse, and as the shipper in India gets the advantage of the difference in exchange, this sum of eight annas is really equal to tenpence, which is the cost of a pound of tea laid down in London. The average price realized is as near as may be one shilling and sixpence, so that, given a properly managed garden, tea ought to pay and pay well. The great anomaly is the vast difference between the price realized by the grower and that paid by the consumer. The average price realized at the Mincing-lane sale being 1s. 6d. makes the entire cost to the tea merchant, with duty added, 2s. per lb., and this is very much less than the *average* price paid by the consumer. We do not grudge the grower his profit, as he has to risk his money, and frequently suffer losses from bad seasons and other causes, but the middleman gets the lion's share.—*Friend of India.*

* We need scarcely remind our readers that coffee found its way to Mocha, or rather the ranges of Arabia Felix, from Abyssinia.—ED.

CEYLON COCOA.—16 cwt. of Mr. Forbes Laurie's cocoa has realized at R54 per cwt., the parcel being bought for despatch to the continent.

INDIAN TEA IN AMERICA.—We find the following paragraph in the *Pioneer*:—The Honorary Secretary of the Calcutta Tea Syndicate writes:—"With regard to the American demand, I may state that the advices of the agents of the Syndicate are most encouraging as to the future prospects of the trade in Indian teas. The quantity hitherto shipped has not been large, and will unfortunately not be sufficient to last till the first shipments of the new crop arrive from this side, but the committee hope to be able to send forward full supplies this season. Upon the strong recommendation of our new York agents, the committee have sanctioned a liberal expenditure for advertisements in all the principal newspapers throughout the United States, and all that is now required is, as you suggest, that gardens should make ample contributions of tea to meet the demand which will no doubt follow."

THE CALCUTTA "ENGLISHMAN" ON COFFEE PRODUCTS.—"It is estimated that the world's total consumption of coffee reaches now 550,000 tons [11,000,000 cwt.] per annum. Of this the European consumption amounts to 370,000 tons [7,400,000 cwt.] and the American to 180,000 tons [3,600,000 cwt.] The increase in Europe has been at the rate of about 10 per cent. in every five years, but in America the demand has grown more rapidly, the increase being on the average 35 per cent. in every five years. By far the chief portion of the supply comes from Brazil, the crops thence for next season being estimated at some 360,000 tons [7,200,000 cwt.] Ceylon will, it is thought, give not much more than 30,000 tons [600,000 cwt.] The remainder of the supply comes from portions of Arabia (a very small quantity, but of first rate quality), from some of the West India Islands, the republics of Central America, some of the settlements on the east and west coasts of Africa, and two or three islands in the Pacific, Java and Madras, Java being the greatest producer in the world after Brazil. Coffee is said to be at present in a state of over production. A surplus stock of some 35,000 tons [700,000 cwt.) is believed to have remained over the year in the hands of the dealers. A bad harvest in Brazil is therefore at present their hope, but there does not appear to be much chance of its fulfilment, the season in Brazil having been so far all that could be desired. The over production has not, it seems, as yet made itself felt to any extent among the planters in that country, the loss falling entirely on the dealers who have been too sanguine in their purchases. Existing plantations in Brazil, while not being extended, are yet not being curtailed. If the planters pursue the same policy for a few years more and are not in a hurry to extend their gardens, consumption will, it is estimated, overtake the production by 1887. By that time the annual consumption in Europe will, it is reckoned, have increased by not less than 35,000 tons [700,000 cwt.] and in America by at least 40,000 tons [800,000 cwt.] The coffee trade has thus a prosperous future to look forward to. Some of the more sanguine dealers believe that even should the Brazil planters continue to extend cultivation in obedience to a growing demand, they will not be able to go on with that operation much further, for they hold that the limits of production have been almost reached, by reason chiefly of the insuperable difficulties connected with an adequate supply of suitable labour. This fact should encourage the the desponding planters in Madras and Ceylon."

In the above article, we have reduced the tons to hundredweights in every case, as that is our modest way of counting in Ceylon. In regard to further extension in Brazil, the factor of disease in the coffee bushes, as well as that of labour, must be calculated.

KELBURNE CINCHONA TREES.—The nett proceeds of the bark, from the 130 succirubra trees, will be about £440 sterling, or about £3 7s sterling per tree, without root bark The trees were coppiced and are now sending up vigorous stems, only one dead stool being found among the hundred and thirty.—"Ceylon Times."

INDIGO.—It has long been accepted as a truism that he man is a benefactor to the human race, who can make two blades of grass grow where only one grew before. Somewhat in that light, says the *Englishman*, ought indigo planters to regard the patented inventions of Mr. E. Schrottky for improving both the quantity and quality of the produce of the indigo plant. The results of Mr. Schrottky's process invariably obtained a higher market price than the produce of the same factories under the ordinary processes of manufacture.

ADULTERATION OF TEA AND COFFEE IN GERMANY,—In the adulteration of coffee, mixtures of earth, sugar, flour, and coffee extract are frequent; seeds, roots, rye and other kinds of grain, pease, beans, germs, stones of dates, chicory, and mineral substances, venetian red, are extensively used. Ground coffee is often mixed with ground and dried liver of animals. Tea is colored black with graphite, and colored green with Prussian blue and curcuma. Leaves thus treated receive a portion of porcelain dust. Leaves of other plants and trees, hawthorn, willows, strawberry, &c., are colored with substances dangerous to health, and mixed with genuine tea leaves.—*American Exporter.*

LAND SALES.—We are surprized to learn that 146 acres of very fine forestland adjoining Nayapana estate, Pussellawa, were sold at the Kandy Kachcheri on the 31st ultimo, for no more than R20 per acre. Adjoining the forest there is one of the finest cinchona fields in the country, and the purchaser of the block (whose name has not reached us) may be congratulated on his bargain. A few years ago such choice forest would have realized at least R100, and probably nearer R200 per acre. At Kalutara, yesterday, Messrs. Leechman & Co. added to their extensive properties in that neighbourhood by purchasing two blocks of 147 and 175 acres, respectively, at a little over upset price. This land is intended for Liberian coffee and rubber, for which it is very suitable. We are glad to learn in this connection that a careful trial is to be given to carbolic acid vapour as a cure for *Hemileia vastatrix* on a ten-acre field on Udapolla Liberian coffee plantation, under the careful direction of Mr. Jardine, whose opinion of the result will be awaited with interest by the planting community.

CEYLON TEA.—Yesterday (June 7th) at Messrs. Robinson & Dunlop's offices, Mr. Maclaren, of the Calcutta firm of Messrs. William Moran & Co., tea and indigo brokers, tasted and valued a good number of samples of Ceylon teas, in the presence of the agents of the properties where the teas were grown and made. None of the teas were valued under 1s 2d some as high as 2s and even 2s 4d. The samples tasted on this occasion shewed how much we have yet to learn in Ceylon in *making* tea: many of the samples shewed under or over fermentation, and one sample was declared to be nearly approaching vinegar in taste, an opinion which caused a hasty retreat on the part of the proprietor who was present. There were also many instances of overfiring. Much satisfaction was expressed at the information so kindly given by Mr. Maclaren, whose long practical experience as a tea-taster and in tea generally entitles his opinions to the deference they meet with in Calcutta. Mr. Maclaren thinks very highly of the future of Ceylon teas, if their growing and making become primary considerations and are not made secondary to coffee and cinchona.—"Ceylon Times."

THE POPULATION OF ASSAM appear to be better off than in any other part of India, owing to the great abundance of culturable land, the light assessment, and the high prices commanded by every kind of labour. It is said to be rare to find a cultivator who has not laid up in his granary food sufficient for two or three years' consumption, and should he have any difficulty in selling enough of the hoarded grain to pay rent or revenue, a few days' labour on a tea plantation or on the roads will place him in possession of a sufficient sum for the purpose. The heavy fall last year in the price of rice caused some embarrassment, but matters are gradually re-adjusting themselves.—*Pioneer.*

THE DUTY ON COFFEE.—According to Mr. Gladstone, the duty on coffee in 1881 was only £189,000. As a source of revenue to the Home Government, coffee occupies a rather insignificant position, and the question arises whether the duty might not be advantageously abolished. In 1867-8, the duty on chicory, cocoa and coffee combined, yielded £523,000. The revenue derived from the same sources in 1874-5 had fallen to £310,000, and in 1881 to £306,000. In 1872 the duty on coffee was reduced from 3d to 1½d per lb. The social movement adverse to alcohol has had no effect on the consumption of the berry, though a marked increase is shown in the consumption of tea, the revenue from which has grown from £3,350,000 in 1867 to £4,200,000 in 1881. It seems to us that it would have been better to have abolished the coffee duty altogether, leaving the manufacturers of spurious articles to be dealt with under the Adulteration Act. The repeal of the duty would have been a boon to the coffee planters in Ceylon and Southern India, while the loss of revenue to the Home Government would have been insignificant.—*M. Mail.*

INDIAN TEA ESTIMATE FOR 1881 82.—From a statement which has reached us from the Indian Tea Association, we are enabled to place before our readers the estimated and actual crops of 1881 and the estimated and probable crop of 1882. The figures have been obtained from the various tea agency firms in Calcutta and from the proprietors and managers of gardens. Last year's estimated figures proved about 11¾ per cent. in excess of the actual crops. The estimate for 1882 has been reduced to make allowance for this excess. The following are the figures for the years 1881 and 1882 respectively :—

CROP OF 1881.	Estimated.	Actual.
Assam ...	28,347, 00	24,390,372
Cachar and Sylhet ...	15,018,180	13,903,016
Darjeeling and Dooars ...	7,730,920	7,403,293
Chittagong ...	880,880	746,895
Other districts ...	2,116,900	1,935,000
	54,093,880	48,378,936
CROP OF 1882.	Estimated.	Probable.
Assam ...	29,373,318	25,272,000
Cachar and Sylhet ...	16,347,030	15,133,000
Darjeeling and Dooars ...	8,755,672	8,384,000
Chittagong ...	836,720	709,000
Other districts ...	2,320,400	2,121,000
	57,633,170	51,619,000

The local consumption of Indian tea, including the requirements of Government, may be taken at 1½ millions of lb., and if, as is hoped, the shipments to Australia and America should amount to 2 millions, there will remain from the probable crop of 1882 about 48 millions of lb. for export to the United Kingdom. It is possible gardens may work nearer their estimates of outturn in the current season than in the past, but the General Committee consider the figures given as the probable crop of 1882 will be found to be a fair estimate.—Calcutta *Englishman.* [The probable outturn of Indian tea being 51,619,000lb., Ceylon will more than make up the round 52 millions.—ED.]

CINCHONA FEBRIFUGE.—Quinine is being steady, surperseded by the cinchona febrifuge produced in India. It is now in general use in Government hospitals, and enters largely into private practice. Only 3,964 lb. of quinine were imported last year, as against 7,409 lb. in 1879-80.—*Madras Mail.*

WHAT WE OWE TO THE TREES.—A country cannot continue to be populous, nor highly civilized when its forests, or their equivalent in coal, are lost to it. But this loss has been experienced by many nations. The whole Eastern world was once well wooded. Roman and Greek writers assure us of this. Vast regions of Europe and Asia, by wars and wantonness and imprudence, have been stripped of their forests. A belt of woodland stretching from the Pyrenees to the Himalayas has been swept away, and that whole region, once fertile and populous, now barely sustains a people scanty in numbers. It is a significant fact that great deserts now occupy the original seat of the human race, and extend on every route of their migrations. Humboldt is reported as saying: "Men in all climates seem to bring upon future generations two calamities at once—a want of fuel and a scarcity of water." The two come alike from the destruction of forests. —*Harper's.* [This reminds us of a Sinhalese servant's delight with a planter's bungalow on a newly formed estate, with firewood all round and a full stream of water running past the kitchen. It was to him, accustomed to pay for firewood and even water in Colombo, a land flowing with milk and honey !—ED.]

THE PROHIBITION OF THE SALE OF DATE DUST AND OTHER RUBBISH AS COFFEE is thus noticed in the *Planters' Gazette* :—

The manufacturers of date, fig, maize, malt and dandelion coffee, and the host of ingenious persons who worked up carrots, cabbage stalks, and other refuse into a semblance of the best plantation will find their occupation gone since they can no longer give their worthless rubbish a fictitious value by misappropriating the name of coffee. Henceforward they will be compelled to sell their wares for what they really are, which simply means that they will find no one foolish enough to buy them. The step is therefore a highly important one in the right direction, but we cannot help hoping that, when the Adulteration Act is under discussion, it may be possible to insert a clause completing the protection which producers and consumers alike have a right to demand. We mean a provision by which retailers of coffee and chicory mixture should be compelled to state what are its proportions, and to abide by the consequences of misrepresentation. This seems to us to follow as a natural corollary, and it would involve no undue hardships on honest tradesmen nor interfere with legitimate business. It will be observed that Mr. Gladstone was induced to lay an embargo upon coffee mixtures other than chicory simply from revenue considerations, and not because justice to the coffee grower and consumer demanded it. Possibly he thought that, as Chancellor of the Exchequer, the principal aspect of the case was alone within his purview, and, being convinced that consumption, and hence the customs revenue, suffered through wholesale adulteration, he resolved to stop it. This fact, however, demonstrates the wisdom of those who have been conducting the agitation here, for it was precisely this point that they thrust into prominence, and at the same time they refrained advisedly from any attempt to interfere with chicory, well knowing that their position would only be weakened thereby. In congratulating our planting friends in Ceylon, South India, and Jamaica, upon what has already been achieved, we must not omit to say that they are largely indebted for it to Mr. H. Pasteur, of the well-known firm of Patry & Pasteur, by whom this movement was initiated, and who has spared neither time nor trouble to carry it through. It is impossible, indeed, to read Mr. Gladstone's speech without the conviction that he has been impressed by the arguments advanced in Mr. Pasteur's able letters since he adopted substantially the same line. The London Chamber of Commerce must also come in for its share of the credit, as it took up the cause *con amore.*

COFFEE AND CHICORY.

There can be no doubt that Sir James Elphinstone is right in the letter which we publish elsewhere, and the Planters' Association and Chamber of Commerce of Ceylon ought to give the British Government no peace until coffee is placed on precisely the same footing as tea. The permission to mix even chicory opens a wide door for fraud as well as for the deterioration of taste if not health by the sanction given to proportions up to 90 per cent of the ground root. Here is the definition of chicory from an impartial authority, Webster's American Dictionary :—

CHICORY—*n* [Fr *chicorée*, It. *cicoria*, *cicorea*, Lat. *cichorium*, (*Bot.*) A plant of the genus *Cichorium*, or succory. *C Intybus*, or wild chiccory, is extensively cultivated and used for adulterating coffee, the roots being dried, roasted, and ground with the coffee-bean.

We said years ago and we repeat our statement now that representative planting and mercantile bodies in the coffee-growing British dependencies will not be doing their duty until they make this very real grievance the occasion of an annual memorial to the Treasury. To allow mixtures of "coffee and chicory" to be sold without specifying the proportion of the latter as a check upon retail dealers, is to perpetuate a gross injustice towards both the producer and consumer. But better far than to specify the proportions would be to forbid all mixtures, "the working man" buying his coffee and chicory separately in the same way,—as Sir James Elphinstone well points out—as he now buys his tea and sugar. We readily acknowledge that in this matter the Conservatives have held views sounder and more just in our opinion than successive Liberal Governments, and ever since, in 1870, Mr. Rucker, senior, personally recounted to us the history of his prolonged agitation and his repeated rebuffs at the Treasury, we have looked for redress with more hope to Mr. Hubbard's and Sir James Elphinstone's political friends than to the other side. Mr. Gladstone has, however, done a certain amount of justice at last to the coffee interest, but by no means a full measure ; and the sale of coffee pure and simple, like tea, cocoa or sugar, ought to be the claim of every producer, merchant and right-minded colonist, until the full remedy is applied. We trust Sir James Elphinstone's timely appeal will bear fruit both in the Kandy Association and Colombo Chamber. The tender of thanks for the concession already made—or rather the wrong so far righted—ought to be accompanied by a request for full justice to an important and much-tried industry affecting India as well as Ceylon and the West Indies. Like Oliver Twist we must all cry out for "MORE," and if we only cry with due zeal and persistency, we are certain with so good a claim, to get what we want.

SIR JAMES ELPHINSTONE ON COFFEE ADULTERATION : A CALL TO FURTHER AGITATION AGAINST THE MIXTURE OF CHICORY. —THE COLOMBO HARBOUR WORKS.

LONDON, May 1st, 1882.

DEAR SIR,—I enclose the Treasury minute prohibiting entirely the introduction and sale of these vegetable substances which have hitherto acted so prejudicially on the consumption of our staple :—

3. *Resolved* :—That the duty of excise on vegetable matter grown in the United Kingdom applicable to the uses of chicory or coffee (other than chicory) shall cease to be payable, and the sale or exposure for sale of any such vegetable matter in imitation of, or mixed with, chicory or coffee shall be rendered illegal.

4. *Resolved* :—That, towards raising the Supply granted to Her Majesty, the duties of Customs now charged on tea shall continue to be levied and charged on and after the first day of August, one thousand eight hundred and eighty-two, until the first day of August, one thousand eight hundred and eighty-three, on importation into Great Britain or Ireland (that is to say): on

Tea... ... ... the lb. 6d.

5. *Resolved* :—That the duties of Customs on vegetable matter applicable to the uses or chicory of coffee (other than chicory) shall cease to be payable, and the importation as merchandise of any such vegetable matter mixed with coffee or chicory shall be prohibited.

Chicory is still permitted to be mixed with coffee and we ought not to cease our endeavours until we enforce the separate sale of the articles. The plea is that a portion of chicory improves coffee. If so, which I am not disposed to admit, let those who like it use it as suits their taste. Every one uses sugar with tea, but I never heard of tea being sold mixed with sugar.

Tea is guarded from all admixture. Why should not coffee be equally protected? the Government could not resist the influential power brought to bear on them by Mr. Hubbard, and, if they insist on coffee and chicory being sold separately, it could not be permitted to continue in the present unsatisfactory practice.

The influence of your journal can do much to stimulate and continue the agitation, and a petition on the subject sent to Mr. Hubbard to the above effect would enable him to obtain a concession so just and so reasonable.—I remain, dear sir, yours very truly,

J. D. H. ELPHINSTONE.

COFFEE "AS SAFE AS THE BANK OF ENGLAND.

In these days of depression and despondency among nearly all connected with coffee planting in Ceylon, it is a real pleasure to meet with a gentleman who, with large experience and great responsibilities, can testify to a prosperous coffee planting enterprize under the care of Europeans, and in a place so near at hand as the Bamboo division of Coorg in Southern India. Mr. Meynell, the gentleman we refer to, is agent for the plantations of the late Mr. Donald Stewart ("King of Coorg"), once in Ceylon, as well as for several other properties, and, after eighteen years' experience, he has no hesitation in saying that at no previous period was coffee doing better or the enterprize on a surer basis than it now is in the "bamboo" land in Coorg. The "borer" is no longer a persistently troublesome enemy, indeed, it seems to have almost disappeared, while the Coorg planter thinks very little of the leaf fungus *hemileia vastatrix*. But Mr. Meynell does not attribute the comparative exemption from what is our worst foe in Ceylon, to any particular kind of coffee—Nalkanaad or otherwise— as Mr. J. S. Middleton led us to infer. Mr. Meynell rather agrees with what Mr. R. H. Elliott of Mysore told us about the good effect of shade. One uninterrupted expanse

fifteen by ten miles of coffee-planted land in Coorg is so thoroughly shaded that from a contiguous eminence a stranger would suppose it to be all forest. The testimony to the value of "shade" for coffee (at an elevation of from 3,500 to 3,800 feet) is so opposed to nearly all experience under similar circumstances in Ceylon, as to be unaccountable were it not for other advantages possessed by the fortunate planters referred to. The "bamboo" land under shade is amongst the richest in the hills of India: three and four feet deep of virgin forest mould and free rich soil is not uncommon, and the climate is so forcing, and yet dry, that the coffee has no difficulty in forming and setting blossom—indeed, the shade probably prevents the blossom being burnt off. The prolonged periods of drought in Coorg go a great way to account for the freedom from leaf-disease. But more remains; high cultivation has been systematized to such an extent that, as Mr. Meynell says, coffee cultivation is now as carefully conducted on the generally flat bamboo land as market gardening is at home. The late Mr. Stewart laid down the rule that, for every bandy-load of coffee transported to the coast, a load of manure must be carried back. This is easily managed, because there is no rice or food supplies to be carted for coolies. The labourers buy their rice freely and cheaply in the surrounding villages, and the Coorg planters have now a superabundant supply of labourers. Mr. Meynell's constituents have their own manure works on the coast, importing the raw material—coprolites, bones, and guano—direct, and preparing and mixing them in their store. That "bamboo" estates are well supplied with fertilizing substances as well as kept perfectly clear of weeds, will be understood when we mention that the rate allowed for expenditure is equal to R100 per acre. In Ceylon during these "hard times," plantations are worked for less than half this amount, kept clean, but not of course manured. Indeed, we know of estates in good order on which the expenditure does not exceed R30 and R40 per acre, one-fourth of which again is allowed for superintendence; but, alas! this includes no manure, and it is very evident that, if we are to see good crops of coffee here again, expenditure in fertilizing substances must be incurred. Meantime we can only wish our Coorg neighbours a continuance of their good fortune and equal success in the cinchona enterprise (more particularly with Ledger seed) which they have lately begun. We may mention that the Nalkanaad coffee seed received in Ceylon shewed no exemption from the leaf fungus: the plants in the nursery were very severely attacked, but not killed out, as was the case with a nursery formed out of an importation of very fine picked Java seed which two Dikoya planters got over at considerable expense some years ago. This Java investment was a complete failure.

It might be worth trying in a corner of the Badulla district—with good soil and a hot dry climate—whether the cultivation of shade trees after the Coorg fashion would save coffee from the fungus; but then the shade ought to be backed up by liberal cultivation, and how can manures be transported and applied without railway extension?

THE TROPICAL SWING: PROSPERITY AND DEPRESSION.

(The views of an old planter and merchant.)

The sketch given in your leader of the 1st inst. of the present state of agricultural depression in Ceylon and of previous ebbs in the tide of local enterprize is true and very interesting. Still, whether regarded as a historical sketch, or as a view of the present as compared with former periods of depression, it is, of course, incomplete. As far as it goes, neither friend nor foe could gainsay a word of it; but, as a friend of the Ceylon planter, I feel strongly tempted to add a few words.

Historically, when the present situation of agricultural enterprize is compared with past periods of depression, the parallel soon fails. There are some general points of resemblance, but also strongly marked differences. The points in which the depression of the present time resembles those of former visitations are obvious; but the differences are not so evident, even to those who, like myself, have witnessed and closely watched all the successive ebbs since 1846. Reduced incomes; forced restrictions of domestic and national expenditure; stagnation of trade and commerce; and individual distress and ruin have, in all such periods, produced their inevitable train of miseries, personal and general; but even these common results of adversity have been intensified in this last, and still present, period by its unprecedentedly long duration.

In all our disasters, the indomitable spirit of the planters has been conspicuous, but in no previous period has this characteristic been so strongly developed as in this long protracted ebb, persistently pursuing its course through a whole decade. If, in the earlier years of this period, high prices sustained the hopes and energies of the planters, and, if good crops, alternating with the disastrously bad ones, helped to keep up their spirits; yet, the fact that each successive alternation showed a fateful decline upon the one preceding looked portentous and shook the very ground work of their hopes. And when, at length, the crop which, in accordance with previous alternations, should have been a large one, proved to be the worst of all, the sickness of deferred and disappointed hope struck despair into many a brave heart. Still, the culmination of misfortune was yet to come. A heavy fall in prices brought about a climax, of which our previous history furnishes no example. The long-protracted ebb, wrought by a combination of elemental disturbances, natural pests, and financial difficulties, during which so many brave men have been stranded, has no parallel in any former period.

In 1846 the blow to our enterprize was sharp, beyond all the disasters we have suffered since, but it was *short*. The fall then was terrible, but it was one frightful plunge, in which the utmost depth was reached at once. Recovery, though slow and painful at first, began almost immediately after the shock, and was steady and progressive. The planter realized at once the full measure of his misfortune, and was not then subject, as he has lately been, to the frightful ordeal of successive falls, in each turn bringing new disappointments, and landing their victims in still lower depths of ruin.

Another strongly-marked point of difference between this last and previous periods of depression, is in the comparatively few changes of proprietory. In 1846 a convulsion of the agricultural enterprize was caused by the immense number of estates which changed hands, and which during the change were, in many cases, allowed to fall into neglect. At that period many estates were deluged with weeds and a prey to disorder, presenting a picture of desolation and ruin.

A stranger visiting our country now would hardly believe in the fact of agricultural depression, if h judged by the beautiful order which almost every wher

prevails on our estates. He would rather believe from the numerous young products springing up amongst the coffee, in a rejuvenescence than a decay of enterprize. He could see far more signs of vigorous young life than of decrepitude and decline. He would be much more likely to infer an influx of new capital into the country than an utter depreciation of the old. He would leave the groaning circles in Colombo expecting to find the coffee fields wasted, leafless, barren, and would find them luxuriant with coffee, still showing wonderful order and vitality, and with numerous rival products ready to take its place or supplement its shortcomings. In truth, there is no feature of the present crisis in which it contrasts so strongly with all its predecessors, as in this wonderful order, vitality and promise visible on all the estates.

There are other points on which, as an old fogey, I might be tempted to prose, but I will venture to mention only just one more point of difference between 1846 and 1882.

The planter of 1846 thanked his stars he was not married. Poor fellow; he knew no better! On the other hand, he of 1882 *may*, and perhaps *does*, feel how much of all that has kept his head above water, during this period of ever-recurring visitations of misfortune, has been due to the gentle, but never failing influence, inspiration and encouragement of a wife, and to the unspeakable solace of a *home* and a *companion* in his trouble. If, in some rare case, the family care has intensified the sharpness of individual suffering, in the great majority of cases, family comforts have fortified the energies of the struggling planter, and minimized personal and individual misery. The planter of 1882 owes to the influence of woman the greatest comfort, the most wholesome stimulus, and the most effectual encouragement he has had to help him in his difficulties; and, in many cases, he owes to her the generous forbearance of his creditor! When better times come, and, of course, they must come, or else the *end of the world*, because, you know, Ceylon planters are not the only people whom this wave of agricultural depression victimizes; they only share a common lot, and they are sure to rise along with the rest. I say, when good times return, we must not forget how much gratitude we owe the ladies. I conclude this bit of old fogeyism with hearty good wishes to the planters and best cheers for those real heroines, their wives. G. W.

INJURIOUS INSECTS.*

The authoress of this useful book has long been known for her labours in the department of entomology, and has furnished us for several years past with various useful notes and observations on injurious insects.

This manual will be found of much interest to Ceylon planters, entomologists, and also to the meteorologist.

Although many of the insects referred to do not exist here, yet there are many of the same genus around us. The timber trees, the cultivated crops, etc., vary much from a temperate climate, and such a manual as this, referring totally to the injurious insects of Ceylon, would be of very great value.

We have a small book (Nietner's) which tells us about the enemies of the coffee tree, but new products are rapidly extending, and they have already or will soon have their insect pests.

Some such plan as that adopted by Miss Ormerod might be carried out here. Let all those interested in the welfare of their crops furnish as many notes and observations on their various pests as they have time for. This treatise of 323 pages is based to many "pects on Curtis's Farm Insects" and many of the illustrations are from that book or from the pencil of Professor Westwood. A great amount of information is compiled from previous writers, supplemented with the records of all those who have so willingly rendered Miss Ormerod aid. Although our insects are very different, yet we notice in the text several akin to our coffee pests. Thus we have here *aphis coffea*, and in the manual there are noticed 10 of the aphides with useful advice as to keeping them in check. Again we have *Zeuzera coffeea* and *Tortrix coffeea*, enemies of the coffee bush described by Neitner. In the manual, we notice:—*Tortrix viridana*, the oak leaf-roller moth, which causes serious injury to the oak forests of Europe, and also *Zeuzera æsculi*, which bores into many of our useful trees at home, such as the pear, apple, ash, horse chesnut etc. The white grub of the family melonthidæ has its family represented in the manual by melontha *vulgaris*.

The introduction to entomology will be of great use to a beginner on the subject, and the authoress is to be congratulated on the interesting and well illustrated manual.

* A Manual of Injurious Insects, with Methods of Prevention and Remedy for their Attacks to Food Crops, Forest Trees and Fruits; with a Short Introduction to Entomology By Eleanor A. Ormerod, F. M. S. (London: W. Swan Sonnenschein & Allen; Edinburgh: J. Menzies & Co. 1881.)

TEA IN CEYLON.

A very good proof that tea has found a congenial home in the hill as well as low country of Ceylon is afforded by the case of an abandoned estate in a medium district of which we heard the other day. A new clearing at an elevation of about 3,000 feet after being planted with coffee, cinchona and tea was, about two years ago, neglected and finally abandoned. Weeds and cheena soon took possession of the cleared land choking out the coffee as a rule and playing havoc with a good many of the cinchona, though not a few have struggled on to a size which makes them worth barking; but the tea bushes have held their own against weeds, lantana and chena. A large number of them are most flourishing, and altogether the tea-plant in this abandoned clearing looks as if it had found its habitat.

Throughout several districts with heavy rainfall and in fields where coffee is undeniably not a success, tea seed is now being put out at stake between the coffee: in others nurseries are being formed for plants which will be ready to put out during next planting season. Everything points to a large addition to the planted area under tea during 1882-3, and where the cultivation of coffee, in good heart, and of promising cinchona is conjoined, there should not be much doubt of the success of this new venture.

CASTOR OIL PLANT.

Mr. J. Inglis writes:—I was asked a short time ago by a well-known firm in town to write answers to a series of questions on the cultivation of the castor oil plant. The information was wanted for some young planters in Fiji, but I have thought that possibly what little information I am able to give on the subject might be of use to some of your readers. I do think you will credit me with a simple wish to see my adopted country go ahead and develop its resources. That is my only excuse for putting the following information at your disposal. I believe castor might be made a profitable crop, and the product is a valuable one. The letter is as follows:—

"Dear Sirs,—Yours of 6th, *re* 'cultivation of castor oil plants,' to hand. What information I have is heartily at your service. I used to grow the plant largely in India, but it was such a common crop that

really I did not bestow on its culture that minute attention I might have done. I have grown it here (Redmyre); it flourished luxuriantly even in the dry weather and bore well, and in many parts of the colony it grows 'like a weed,' and is looked upon as one. I will try now to reply to your questions seriatim:—1st. Best Distance to Plant: Average Soil.—It is a shrubby plant, with a tendency to branch and grow straggly, if neglected, perennial in warm climates, although an annual in Europe, will thrive on any soil, will stand hot winds, is suitable even for arid lands, thrives luxuriantly in good soil, and should be 'nipped back' when making too rapid growth, as this tends to increase productiveness. In India' indigo planters usually grow it along the tops (or banks of the ditches), alongside the factory roads. The natives line the tops of their earthern boundaries alongside their gardens and orchards with the plant. It is also used to crop poor, sandy exhausted fields, as it seems to give a rest to lands which have been cropped with cereals, pulses, or grasses. When thus planted in fields it is 'set' as thick as vines in a colonial vineyard; three to four feet average distance where good cultivation is followed; many ryots sow it broadcast, and thin out to suit their own ideas. It would be the best plan by far to sow in lines and earth up, much after the style of vineyard cutivations here; or use the plant as an outside crop, *i.e.* planted on the 'head rigs' and belts of 'tail' lands, round other crops, such as tobacco, cane, &c. In this way it forms an admirable 'breakwind,' and, if allowed to grow up, economizes space; and, being a very hardy, quick grower, it gives a quick return in produce, besides being valuable as an aid and shelter to the other staple crops. 2nd. When First Crop Ripe:—It should begin to produce in about four months from sowing—sometimes less even than that where circumstances are favourable. Keep 'topping back' the shoots and induce as shrubby a habit as you can; and picking can then go on indefinitely. By-and-bye you will have to lop off old wood; and, indeed, you must cultivate for branches and seed, and not for leaf. 3rd. Yield.—Impossible to estimate this; so much depends on soil, management, picking, &c. You should experiment only at first. There are thousands of other products equally valuable. Go in for, say, an acre, or even ten acres, of castor, a specific quantity of tobacco, cane, grain ginger, safflower, &c., &c., and note carefully the results. You will soon find what pays best. Get Baron von Mueller's 'Select Plants for Industrial Culture in Extra-Tropical Countries.' Subscribe to the *Tropical Agriculturist*, published by Fergusou's *Observer* office, Colombo, Ceylon, and read up. Trees will grow on, bearing so long as they are tended. We used to get so much from a certain range of bank along well-known factory roads, so that I regret I cannot answer this question with exactitude. Baron Mueller says of it:—'The easy and rapid growth, the copious seeding, and the early returns of produce render this important plant of high value in the warm temperate zone,' &c. 4. Most Remunerative Form to Sell Produce:—Oil decidedly, chiefly because you save freight. It is better to sell bacon than ship maize, to ship coconut oil than copra or nuts, oilcake and oil than bags of linseed. The seeds contain 50 per cent. of oil: the refuse forms goods manure, and parts of it can be made into soap. See page 290, Von Muller's 'Select Extra-Tropical Plants.' 5. The oil is used both crude and refined. 6. The stages of manufacture are:—1. Picking. 2. Drying in the sun. 3 Husking. 4. Extraction by hydraulic pressure. 5. Bleaching. 6. Filtration and purification. The secondary process is to again treat the pressed mass with heated water, which gives a second quality of oil; and, thirdly, saponaceous matters are afterwards obtained, and the refuse mass is useful as a manure. The leaves from a good fodder in seasons of drought, and are a good feed for a species of tussur silkworm, tho Bombyx Arrindi." 7. Value of product.—That you know is 3s 3d to 3s 6d per gallon. 8. The market is capable of indefinite expansion. It is, I believe, the cheapest and best lubricant we have. The customs returns will show what are our imports. All our sugar, mining, locomotive, and other machinery should be lubricated with our native-grown castor oil. We should not be dependent on any but ourselves for a solitary gallon, assuming of course that we can make it cheaply enough. 9. Could be sent to market in barrels, puncheons, tins, skins, jars, or in the way that best suits the locality where grown. Present supply chiefly from India. 10. Special plant required would be presses; ordinary intelligence should make a good oil miller. It would be no use trying to make the finer qualities without steam machinery and a fair knowledge of chemistry. The planter's work is to make the crude oil and send it to market. The refiner will do the rest. For lubricating purposes, which is its chief use, refined oil is not needed. The want of cheap labour may have militated against the Queensland attempt. But I do not know anything of the particulars."—*Queenslander.*

HOW TO INCREASE THE CONSUMPTION OF COFFEE.

(Communicated.)

When Mr. Gladstone made his late onslaught on coffee adulteration to court favor, it may be, with the vote of the grocers, he barred chicory. Mr. Pasteur, in spite of the bad odour his action has brought upon him, owing to the interests of middle parties being interfered with, perseveres in his good work. Why does not Mr. Gladstone do the same and sit upon chicory too? London *Truth* made some very pertinent remarks with regard to the fragrant berry, saying it was a question of "first catch your hare." The hare seems to be in a fair way of being caught; so I would say the question now resolves itself into "catch your coffee-roaster."

The want of a really A 1 *cheap* roaster stops the consumption of coffee in the United Kingdom. It appears to me that one could be made for a couple of shillings or so on the principle of the cheap oil cooking stoves, now being advertized, having the advantages of being "lit and extinguished in a moment, smokeless and without smell, and the cost of the oil used being infinitesimal."

The Gaslight and Coke Companies, now being formed to lend on hire stoves for heating and cooking purposes, might also with advantage add coffee-roasters to their stoves. Depend upon it if rich and poor had some easy and sure method whereby they could roast coffee for themselves we should see a vast increase in the rate of consumption per head. I now write, however, more on behalf of the working classes, and a cheap and expeditious oil coffee-roaster would probably meet their case best (for the use of such oil just now for lamps is pretty universal, (where gas is not used), so that the material would always be ready to hand, and the kitchen fire, otherwise employed perhaps, at the time, would not be interfered with.

If the different Temperance Associations are in earnest (and who can doubt it, seeing the enorm-

ous sums they spend annually in furtherance of their object?), let them start a penny subscription, and offer a substantial prize for the best and most reliable and economical coffee roaster for the working man. The amount of the subscriptions would make up a large sum, but it would be well spent, for it would assist to free the people to a great extent from the adulteration of coffee left them by our legislature; but more important of all, the working classes would have freshly roasted coffee always ensured to them, and the spread of the delicious aroma throughout our streets and lanes would *soon* make the roaster a household want.

A short paragraph on this question might be inserted with advantage in the *Tropical Agriculturist*, for the question narrowly concerns coffee planters' interests, therefore it is within the scope of that journal. Moreover, the *Tropical Agriculturist* is circulated in many countries (including no doubt America) *where adulteration is rampant*. [This communication will appear in the T. A.—ED.]

Not many years ago it was possible to get really good coffee served to you at the French hotels and cafés. Now *good* coffee in France is almost as scarce as in England. At the time I refer to it was no uncommon sight to see men retailing coffee in the streets, the berries being roasted on the spot as required. Now-a-days coffee roasting is mostly delegated to the grocers, and cheap Brazil and vile mixtures usurp the place of the fine grades formerly used. A *Public Opinion* advertizement sheet received by a late mail has the following:—

HOW TO STUDY ECONOMY!

Use Rippingille's Patent Oil Cooking Stoves.

Odourless, Smokeless, Portable, Safe, and Cleanly.

They will roast joints or poultry, boil fish, vegetables, &c.; fry chops, steaks, or bacon; bake bread or pastry; toast; heat flat irons; and, in fact, do the entire work of a kitchen fire; over which they have the advantage of being lit or extinguished in a moment. They save keeping a fire in warm weather, and for domestic use and economy they are unequalled.

Three Meals a Day for Four to Six Persons can be Cooked for a Penny. Prices from a few Shillings.

Write for Illustrated list and full particulars to 118 Holborn, London.

"The Company is prepared to lend on hire stoves of approved manufacture for heating or cooking purposes. Patterns of various makes and sizes are kept at the Company's offices from which consumers can make a selection. The Company will fix the stoves, supply the material, and make all necessary connections at cost price, an estimate of which, including the annual rent of the stove selected, can be obtained from the Company's inspectors." *Vide* Gas Light and Coke Company advertizement.

A Company has just been formed at Dashwood House, New Broad St., London, for the supply of direct pure coffee, tea, &c., in small quantities—to small consumers. Capital, £10,000.

On the Continent today a vast amount of money is spent in coloring cheap green coffees to resemble fine colory Ceylon, and so probably the Germans and Austrians swallow no end of poisonous pigments while Britishers are dosed with the innocuous chicory.

A COFFEE-ROASTER IN EVERY HOUSEHOLD.

With regard to the idea, suggested in the foregoing, possibly at no previous period in the history of the world could TIME be more truly designated as MONEY than at the present day. Especially is this the case with the working classes. Therefore, the roaster would require to be made on principles admitting of *no waste* of time.

CINCHONA CULTIVATION IN CEYLON.

SOME FACTS AND FIGURES.

Renewed Succirubra bark yielding 5·30 per cent of sulphate of quinine must be considered a valuable product, and this is the return given in a report received by a Ceylon planter from Dr. Paull, the well-known London Analyst. In another case local analyses which gave 2·22 per cent from shavings taken off in September last made the returns from the renewed shavings stripped in February and March no less than 3·82 per cent, while instead of 4 ounces at the former date the owner after some months got 5 ounces of wet bark per tree. This is very satisfactory; but, as if to counterbalance the effect, we have another case presented to us wherein the second analysis after a considerable interval shewed a worse result instead of an improvement on the first! In an exceptional case of this kind it is very important that all the circumstances of treatment of the tree operated on by covering it or leaving it bare, weather after shaving, mode of drying the shavings, &c., should be observed and stated. The opinion has become current now that September is about the best time to strip or shave bark, analyses shewing the amount of alkaloids to be largest then, but the improved return got above in March after seven months' growth was surely as good as could be expected. At the same time, considerable doubt as to the accuracy and reliableness of analyses prevails in planting circles.* More satisfactory

* Since writing the above, we have received the following from a Colombo merchant:—"I send herewith the mail of 8th May with a paragraph on 'Discrepancies in Analyses,' which I think is important. It certainly is suggestive. If such differences occur in analyzing a purely mechanical mixture, how much faith shall we place on analyses of chemical or natural mixture, such as the alkaloids in cinchona bark! Most of us in the Fort have had experiences of very great discrepancies in this direction; and what is to be done to get at *the truth?* In the mail paragraph, the Dr. Dupré mentioned is the same who analyzed the contents of the stomach of the boy Percy John poisoned by Lamson, and on whose evidence we may say he was hanged! And yet he cannot analyse the quantity of chicory in coffee." The extract is as follows:—

"DISCREPANCIES IN ANALYSES.—Some remarkable disclosures of varying manner and results of analyses were made at the meeting of the Birkenhead Town Council on Thursday. Sometime back Mr. Alexander, a Tranmere grocer, was summoned for selling coffee largely adulterated with chicory, a certificate of the adulteration being given by Dr. Vacher, medical officer of health. Mr. Alexander denied the adulteration, and his contention that the coffee was pure was supported by several public analysts, and by the analyst at Somerset-house. The summons was consequently dismissed. On the advice of Dr. Vacher, who persisted in the accuracy of his results after three tests, the Health Committee appointed a sub-committee to investigate the subject. They prepared samples of coffee adulterated in various proportions with chicory, and submitted them to various analysts, with the

evidence is offered as to the good effect of slitting open the bark on young trees, drawing the knife right along the bark (without if possible touching the cambium) from top to bottom. We understand that Mr. Bluett of Kotmale has made a series of experiments in this way, making as many as four and five slits round the circumference of some trees, and that the result is most satisfactory. Canker is in some cases due to the hidebound character of the bark, and relief is at once afforded by the slitting open referred to. But, even where not hidebound, the cutting benefits rather than injures the growth of the tree—or at least of the bark—while a proportion of *renewed* bark is at once begun to be formed, and so little is the risk of injury, that even where the cambium is touched the tree has been found to prosper. Slitting therefore seems likely to do no harm but much good to trees from eighteen months and two years upwards. When general reddening of foliage, however indicates that the "dying out" process has fully set in, slitting the bark does not appear to arrest "the inevitable."

The variety of opinion as to the treatment of the cinchona tree in other respects is still very great among our planters. Some there are who do not believe in shaving and think coppicing more profitable in the long run and more likely to secure sound vigorous growth and prolonged life. There is the great fact that on the Nilgheries, harvests have been taken from trees seven and eight times barked; while others have been coppiced three times with fairly good results. On the other hand a considerable proportion of trees which are coppiced must be expected to perish, a larger proportion certainly than the fatality due either to stripping or shaving. Colonel Beddome and Mr. Cross thought it important that the part of the tree left in coppicing should be pointed pyramidal ashion, but a slanting cut is thought to be as good in Ceylon. Of a large clearing in a medium district coppiced two years ago as many as 30 per cent have been failures; but the rest have made much better growth than the plants now two years old alongside.* Wherever the coppices spring up on the sheltered side of the root, they are apt to break off in the monsoon; not so if to the windward

following results:—A sample, which had been adulterated with 10 per cent. of chicory, Mr. E. W. T. Jones, Wolverhampton, certified to contain 7 per cent.; Mr. Alfred Smetham, Liverpool, 7 per cent.; Somerset-house authorities, 2½ per cent.; not more, chicory; Dr. Davies, Liverpool, 5 to 10 per cent.; Dr. Carter Bell, Manchester, 10 per cent. and upwards of chicory; Dr. Dupré, London 16 per cent. and Dr. Vacher certified the sample to be genuine coffee. A sample, which had been mixed with, 30 per cent. of chicory was analyzed by these gentlemen, with the following results:—Mr. E. W. T. Jones, Wolverhampton, 31 per cent.; Mr. Alfred Smetham, Liverpool, 32 per cent; Somerset-house authorities, 35 per cent, not less, chicory; Dr. Davies, Liverpool, 25 per cent.; Dr. Carter Bell, Manchester, 30 per cent, upwards of chicory; Dr. Dupré, London, 35 per cent.; and Dr. Vacher, 31 per cent. A third sample, mixed with 37½ per cent. of chicory, was certified by Mr. E. W. T. Jones, Wolverhampton, to contain 38 per cent. of chicory; Mr. Alfred Smetham, Liverpool, 34 per cent. Somerset-house authorities, 48 per cent, not less, chicory; Dr. Davies, Liverpool, 50 per cent.; Dr. Carter Bell, Manchester, 40 per cent, upwards of chicory; Dr. Dupré, London, 47 per cent. and Dr. Vacher, 50 per cent.—London *Times*."

* We may quote a few passages from Colonel Beddome's last Report as a further illustration of the different opinions held on points connected with practical cultivation:—

Coppicing.—Mr. Cross objects to such a large area having been coppiced, and states that the trees have been coppiced too low down and that four to five inches of the trunk or collar should have been left. There has always been a difference in opinion as to the height the collar should be, and I find in my letters to Mr. Barlow, the Commissioner at the time (*vide* also G.C., 1,161, of 27th May 1879), that I was anxious to restrict the area to about 3 acres, and that I wished three systems tried as experiments for data: first, to adze the collar flush with the ground; second, to leave about six inches of collar; third, not to coppice without first establishing a shoot. The Commissioner was in charge of the plantations at the time, and I had only been ordered to select the area to be coppiced, and these suggestions of mine do not seem to have carried weight, as they were not acted up to and all the stools were adzed nearly flush to the ground. I have no reason to find fault with the result as will be seen from my report, and I think if coppicing were again ordered and in the absence of actual data, which I was anxious to obtain, I would rather give the preference to the flush collar than to a collar several inches high.

I do not think we shall have more coppicing as a system over given areas. I am much opposed to it for many reasons, and I think my report will go to prove that it is not desirable; but if we did again coppice, I should prefer the plan of first establishing a shoot. It will be seen by my report that when this plan is followed there is not a single failure, and that this is fully proved from several blocks of older experiments which I was quite ignorant of at the time that I made the proposition. Mr. Cross appears to think that the young coppice growth was thinned out prematurely, but I do not understand how he could give an opinion on this point without having seen the growth at the time it was thinned. It is very easy to tell the proper time; it is of course allowed to grow up till there are several prominent leaders; the growth of these would then be seriously retarded and interfered with unless the rest were cut away, and it is then apparent whether it is advisable to leave two, three, or four shoots. Adzing off with a rounded top is in my opinion preferable to a sloping cut or wedge form of coppice.

I cannot agree with Mr. Cross in his suggestions about forming a dense sort of underwood of Chinchona in the plantations; it would be opposed to every system of arboriculture and would be simply ruin to the plantations; the trees that did not get their heads to the light would come to nothing and interfere with the root room of others, and the result would be little or no bark of any value. We are not growing osiers or scrub firewood.

Regarding the remarks on "collection of seed" by Mr. Cross and the Collector, I cannot believe that this has not received attention. "This selection of the fittest" is the first aim of all florists and arboriculturists as well as breeders of animals, and was so long before Mr. Darwin's voluminous wrtings on the subject; a practical man, with the training Mr. McIvor had before he came to this country, must have been fully alive to the importance of this. During my inspection I observed muslin bags tied round the panicles of seed on some of the finest trees, which is proof that attention is paid to this subject. Regarding the cutting off of the panicles of flowers which the young trees produce so prolifically, I would observe that I strongly recommended, many years ago, when the trees first commenced to flower so profusely, that this should be done as an experiment over about an acre, as I thought it would favor the growth of the trees and perhaps

side. The reason why trees as a rule do better on the side below the drain than on the upper side seems obviously to be the exemption from percolation from the drain which carries off the water that would otherwise rot the roots of the trees on the lower side. In the same way it is found on rocky hill sides that plants placed on the lower side of boulders or detached stones almost invariably succeed, being protected from surface wash and also from being damped off. But there are exemptions to every theory that can be deduced from isolated experience and in the case of cinchona it is almost impossible to establish rules applicable all over even on one estate, much less over a district or for the country generally. A practical hand who knows by long experience what "grafting" means, has been trying the art on cinchona after the Matakelly plan and finds success is easily attained; but he prefers a pointed wedge-like graft inserted between two cuts in the stock to the outside splice recommended at Matakelly. Instead of 300 grafts a day, our practical friend considers 50 a good day's work. and he does not believe a cooly can be trained to do more than 40 at his best, if the work is properly done. But even that should be profitable work—costing only a cent a graft. When cinchona was first put out among coffee it was generally supposed that the centre of the square formed by each quartett of coffee bushes was the best place to occupy; but experience has shewn that plants put in the coffee rows rather than between them are much more likely to succeed. The coolies in weeding, pruning and picking between the coffee can scarcely avoid trampling or otherwise injuring plants in the centre of what is their walking path. On the other hand when coolies have been carefully warned and watched, both tea and cinchona have come on fairly well between the rows, and now that self-sown seedlings of cinchona are becoming so plentiful in many estates, those who wish to cultivate this most promising type of young plants must do all they can to prevent their being pulled out for weeds or trampled down beyond recovery.

Since writing the above we have received the following very encouraging report from Mr. Bisset of Kotmale :—

"I have just had some bark analyzed (by Mr. Symons) taken from trees growing on old coffee land—trees six years old. The plants were obtained from New Forest (Mr. Christie), and now give the following results :—9·20 per cent crystallized sulphate of quinine, and, as 'Calisaya Ledger stem bark' is worth 11/ per lb., with Howard's quinine at 9/6 per oz. The bark of a hybrid tree analyzed shewed the following :—4·20 crystallized sulphate of quinine valued at 4/10 per lb. When bark of this value can be grown on land that ceases to be remunerative with coffee, in spite of present depression, proprietors have nothing to fear."

---

the virtue of the bark, and at any rate be a very interesting experiment; but I was met by the statements that it would be too expensive to attempt it in large plantations, and that expensive tools would be necessary, otherwise the branches would be much broken and injured.

The Calisaya will never answer at Naduvatam, but I have written fully on this question in my report. There are four varieties only, "the ordinary Calisaya," "the Ledger," the "Anglica," and the "Javanica;" the two former are known to be most superior; they are scarcely distinguishable, and I shall be surprised if further research proves the "Ledger" so very superior. The very favorable reports on this variety are probably due to the high cultivation of a few individuals; however, I may be wrong. Mr. Rowson told me that "Anglica and Javanica" had been analysed and gave a very poor yield; and this has been found the case in Java, where their cultivation is given up; the last named is only a brushy shrub.

I quite agree with Mr. Cross that grafting could be of no value when the object is "bark;" and Mr. Cross agrees with me that the art of hybridizing would not be at all likely to increase the value of the bark.

Mr. Cross appears to be of opinion that the natural bark may be richer in alkaloid than renewed bark; this is opposed to all the experience hitherto gained. I believe I am right in saying that every analysis has hitherto proved the great superiority of the latter, and that it always fetches a much higher price Mr. Cross is also wrong in saying that a tree once barked will always require to be wrought after the same manner as long as it lives, as it is a fact that trees which have been many times barked are now growing splendidly from coppice.

We must be carefnl not to be guided too much by any report on the analysis of Mr. Cross's thirty small selected specimens. I much fear more harm than good has been done by the analysis of only favoured individuals, and that it is likely to be the result of much annoyance; I do not myself believe in the vaunted superiority of such varieties as "Angustifolia" or "Crispa" over ordinary "Officinalis" nor of "Ledgeriana" over ordinary "Calisaya." It is due probably only to high cultivation or to other favourable conditions appertaining to the selected individual; time only, however, can fully prove this.

WHAT IS A HYBRID AND WHAT IS A *CROSS*?

Mr. Gammie, of the Darjiling cinchona plantations, writes :—

"In your issue of the 26th April, Mr. Bosanquet says :—'That we are led astray by the misuse of the word *hybrid*, and that we should be more strictly correct in looking upon robusta as a *cross* between officinalis and succirubra.' This to me is incomprehensible, for I had no idea that more than one meaning could be attached to the term 'hybrid,' viz., the joint offspring of two *species*. But Mr. Bosanquet would call the joint offspring of two so distinct species as officinalis and succirubra a *cross*. The technical term 'cross,' as I understand it, means the joint offspring of two *varieties* of the *same species*. For instance, that between a shorthorn and a Hereford is a *cross*, and that between an ass and a horse a *hybrid*. It appears to me that, as far as the misuse of the terms is concerned, Mr. Bosanquet himself is the guilty party. His extraordinary assertions about an apparent succirubra of one or two years of age turning into a robusta, and a sucker from a succirubra growing up a robusta, only prove that he is not an accurate observer.

"Cross-fertilization is no doubt, as he states, a matter of daily occurrence, especially among plants—such as cinchonas—with flowers of dimorphic formation, and produces all the good results of robustness and fertility, as Darwin so amply proved; but cross-fertilization, as explained by Mr. Bosanquet, viz., the union of two distinct species, is quite a different matter, and is 'exceedingly rare in nature.' He refers to the so-called hybrid tea as an instance of hybridity, but I look upon it not as a hybrid but merely a well-marked and fixed variety. According to the best botanists (see Flora of India), the 'China'

and Assam indigenous, its reputed parents, are but varieties of the same species, *camellia theifera*, and before a hybrid can be produced there must be a second species. The modest hope expressed that his wonderful suggestions should prove a restorative to some bewildered brains is simply delicious, and we must take it for granted—since the writer says so—that the facts he alludes to are difficult of digestion. I must confess that I have been unable to discover them even after reading over the letter several times.

"Your correspondent 'X.' (2nd May) makes me say that 'there can be no such an occurrence as hybridization among cinchonas,' &c. Will 'X.' be so good as to point out where I have ever made any statement that can, by the greatest stretch of imagination, be construed into anything of the sort? I most distinctly deny ever having done so. Will he at the same time tell us where hybrid hares or rabbits are to be seen? He writes as if such were quite common, but I have never either seen or heard of one. There are, of course, any number of varieties of the common rabbit under domestication, as there are of most other domestic animals: but is there any known instance of the rabbit and hare interbreeding in a state of nature?

"In my last I quoted, as you did, that hybridity in nature is exceedingly rare, and ventured the opinion that no single instance of hybridity among either the indigenous plants or animals of Ceylon could be pointed out, and inferred that hybrids in the South American forests were equally rare, and that consequently, if *C. pubescens* of Howard could be proved to be of Andes origin, we had no right to call it a hybrid. But I certainly did not imagine that these statements could be taken as expressing my belief in the non-occurrence of hybrid cinchonas in this country, where the unnatural—if I may use the term—conditions of cultivation and close proximity of species naturally found a long way apart are most favorable to hybridity. While thinking that the Pata-de-Gallinazo of Cross is a true species, I have not the slightest doubt that there are now many hybrid cinchonas both in India and Ceylon, but at the same time feel convinced that there are far fewer than many people think. With so many notable examples of known hybrid origin among the cultivated begonias and orchids, there is no denying the possibility of hybridism, either by intentional or accidental means, in the vegetable kingdom; but it is none the less true that hybridity in nature is exceedingly rare."

JAS. A. GAMMIE."

"Darjiling, May 22nd, 1882."

On receiving Mr. Gammie's letter we thought it well to "read up" on the subject of controversy. We have accordingly read and noted what Darwin wrote on hybrids and crosses, in his *Animals and Plants under Domestication* (the 1868 edition) and the articles "Hybrid" in *Chambers's Cyclopædia* and "Hybridism" in the latest edition of the *Encyclopædia Britannica*. The article in *Chambers* is, what most of the articles are, *multum in parvo* and reliable. The more elaborate article in the great book is confessedly a condensation of Darwin's already closely packed facts, while the writer, G. J. Romanes, avowedly reflects the Darwinian theory and inferences. All the authorities agree in the application of the term *hybrid* to the offspring of parents belonging to two different SPECIES, the word *mongrel* being used to distinguish the far more common results of the union or crossing of VARIETIES more or less differing from each other. The first is a hybrid proper and the second a mongrel, or more popularly a cross. So rare in nature is the crossing process that the Latin word *hybrida* is derived from a Greek word which signifies an outrage. But when animals or plants are domesticated, what would be an outrage on so-called natural laws becomes the rule, man profiting largely by the result in improved breeds of horses, cattle, sheep and poultry, as also in the increased fruitfulness, or value otherwise, of plants. As a general rule, but admitting of many and striking exceptions, the offspring of two distinct species is generally sterile; the crossing of varieties, on the other hand, generally results in improvement, in quality and in fertility. To this crossing of varieties judiciously pursued we owe such horses as the English racer, such cattle as the shorthorns, and such sheep as the best merinos and southdowns; as also the choicest fruits, vegetables and flowers of our gardens. Much is gained by preserving purity of race on the one hand, but, if in-and-in breeding is carried too far, a cross with another variety is necessary to restore fertility and vigour. The questions of course arise, What is a species? and What is a variety? and often it is not easy to answer. The well-marked variety sometimes only wants a sufficiency of time to become a distinct form with all the qualities of a species, especially that of producing sterile offspring if by the agency of insects or of man it is crossed by a separate species. On the other hand, varieties, like hybrids, have often a strong tendency to reversion: to going back to the parent or original type. Darwin, the foundation principle of whose system is the descent or development of all organisms from a common ancestor, naturally enough occasionally uses the terms hybrids or mongrel convertibly. As our readers are aware, the keen observer who has recently departed, and the members of his school, including now the vast majority of naturalists and scientific men, do not believe that what we call species, or even genera and orders, however dissimilar in habits and characteristics they may be, were created distinct or so existed from the beginning. Creation with the Darwinists who do not deny the existence of a Creator (and many of them, like their master, devoutly acknowledge such an existence)—creation to them signifies simply the production of matter stamped with certain laws under which varied and progressive life is developed,—from the jellyfish to the man of highest intellect; from the lowest cryptogam to the noblest oak or palm. The differences which have arisen and in time stamped themselves on various forms, classified now for convenience sake into species, genera, orders, &c., were due to circumstances of locality and surroundings, abundance of food or its absence, &c. We are old enough to remember the time when to talk of the transmutation of species would stamp a man as being unscientific and ignorant, as much as would his expressed belief in the transmuting of metals. Now the highest order of science recognizes such transmutations in the past as the explanation of all we see in ourselves and in our relatives of the animal and plant world, and looks for such transmutations in the future

as the foundation of all progress. To a Darwinian, therefore, the wonder should not be that the offspring of hares and rabbits (*leporides*) should be fertile after their kind, but that a mule the offspring of ass and horse should be generally sterile; that in many cases hybrids should be invariably sterile and that in a very large number of cases separated species, even when crossed, refuse to produce offspring at all. Darwin very candidly confesses utter ignorance of the laws on which such varying results depend. Mr. Gammie is right and we were and are right in saying that hybridism is the rarest possible occurrence *in nature*; but when man takes either animals or plants in hand, and subjects them to conditions the reverse of natural, there is really no saying what the consequences may be. We regret to say that we cannot join our good friend in his sceptical queries as to the obtaining of prolific offspring from a union of hares and rabbits. Darwin in 1868 wrote that the statement of such results having been obtained was doubtful, but it seems now to be established beyond all possible doubt. The writer of the article in the *Encyclopædia Britannica* writes:—"The hare and rabbit are said occasionally to breed together, and their offspring to be highly fertile when crossed with either parent species." But there is no qualifying "It is said" in the article in *Chambers*—the statement is express and definite:—"The most remarkable example on record of generative power in hybrids is afforded by the experiments of Mr. Rouse of Angoulême, who finds that he can cross hares and rabbits to any extent, and who has thus by breeding *leporides* established a new and lucrative enterprise in agriculture. For a full account of these experiments, which are well deserving of a trial in this country, the reader may consult Brown-Séquard's *Journal de la Physiologie*, vol. II. pp. 374 383. These experiments have inflicted a severe blow on the popular doctrine of the permanence of species." There may be some question still as to the variety of hare used in these experiments. The common hare of Ceylon bears a good deal of resemblance to a rabbit. We suppose the rabbits were the domesticated ones, some of the numerous and divergent varieties, all descended from the small grey wild one; just as the pouters and tumblers and fantails and carriers and runts of the pigeon family trace their descent from and are ever inclined to revert in shape and colour to the blue rock pigeon. We should not now be much surprised to hear that pigeons and bantams had been successfully paired, for we already know that the offspring of the common domestic fowl and the pheasant is a fine robust bird. That sledge dogs should pair with wolves is not wonderful, seeing that such dogs are themselves only partially tamed wolves, but it is startling to hear of a hybrid or cross between a dog and a lioness. As for plants, they are apparently capable of being hybridized by grafting and budding as well as by the intermixture of pollen of different species and varieties: in some cases, actually different genera. On the other hand all man's efforts sometimes fail. A plant will refuse to be influenced or will be influenced injuriously by pollen from a plant of a different species, while in some cases the pollen of a particular tree, used to fertilize the blossoms of that tree acts like poison.

To come to the cinchonas: they are, in their native Andean habitat, scattered in groups amongst other forest trees. Mr. Gammie seems to think that so situated, in a natural state, hybridism, from the influence of insects or otherwise, would not be likely to occur. Investigation might well be directed to this question, for whatever tendency to hybridism is due to the existence of dimorphic blossoms would render the cinchonas, to at least a certain extent, liable to hybridization or crossing, in the case of species and varieties. One wonderful German insisted that *all* the cinchonas cultivated in India and Java were merely hybrids! In that case, it would be difficult to know where to look for species. But whether Darwinians or not, we are all agreed in recognizing specific differences sufficient between *C. succirubra*, *C. officinalis* and *C. calisaya* to constitute them distinct species, although, no doubt, all very closely allied, in the constituents of their bark if not in the botanical characteristics. Of the large-leaved robust *C. succirubra* there are only two varieties. Of the more shrubby and smaller leaved *C. officinalis* there are at least half-a-dozen varieties, and so with the beautiful velvet-leaved *C. calisaya*. Crosses between varieties of the same plant we may look for, and we may expect such crosses to be fertile, and to be sometimes improvements on the original stock. Closely planted as our trees are too, sometimes all species intermixed, and insects abounding, we must also be prepared for the appearance of hybrids between succirubra and officinalis; between succirubra and calisaya; and between the different varieties of the species officinalis and the different varieties of the species calisaya. The general belief is that *C. robusta* is a hybrid between *C. succirubra* and *C. officinalis*. If so the question as to its continued fertility is interesting and important; but here we must pause for today.

A SUBSTITUTE FOR PERUVIAN BARK.

The following is an extract sent to us by our London correspondent: we have little or no belief in the supercession of cinchona bark by artificial quinine and will refer to the matter more fully again:—

Ever since the year 1820, when Pelletier and Caventon discovered that the fever-destroying power of Peruvian bark was due to an alkaline, crystaline substance, which they named quinine, chemists have been searching either for a substitute for this costly medicament, or for a cheap method of making it artificially. Endless substitutes have been proposed from the bitter principle of angostura bark to spiders' webs; but none of them have succeeded in ousting quinine from its position as the first and best of febrifuges. From time to time, too we have heard rumours that some hitherto unknown chemist had discovered the method of making quinine from cheap materials, but the rumours have died away without echo. At last, however, we seem to be on the threshold of something positive in this latter direction. M. E. J. Maumené, a distinguished French chemist, has definitely announced verbally that he has succeeded in making quinine artificially—that is to say, without having recourse to the natural bark. He does not wish to announce the details of his process just yet, as he does not consider them perfect; but he has deposited a sealed packet containing an account of them with the secretary of the French Academy of

Sciences. M. Maumené's announcement is quite clear and distinct, and his reputation as a philosopher is too high for him to imperil it by a premature or ill-considered statement; we may, therefore, take M. Maumene's word that he has succeeded in making artificial quinine. The next question is that of cost, for we may pay too dearly even for artificial diamonds, as Mr. Hannay has shown. Another case occurs in artificial indigo, the process for making which is so costly as to be industrially useless. On the other hand, artificial alizarin, the colouring principle of madder, can be made at a far cheaper rate than by extracting it from that one useful plant, which is now almost driven from the market. Quinine, or rather its sulphate—the form in which it is generally administered—has been rising steadily for the last 15 years the latest Mincing Lane quotation being 10s per ounce, as against 4s 9d per ounce in 1867, and the demand for it is increasing steadily. Its importance may be guessed when we remember that without it India and our tropical possessions generally would be little better than European graveyards. If M. Maumené has succeeded in making artificial quinine at a cheaper rate than by extracting it from bark he has both fame and fortune before him; and the Peruvian bark plantations of South America, India, Ceylon and Java, whether natural or artificial, may be cut down for firewood. If, on the contrary, he can only produce it at a dearer rate, he will have achieved a result that will hand down his name to posterity as the first chemist who succeeded in the artificial formation of a vegetable alkaloid. It may not be out of place to mention that mauve, the first of the large and brilliant family of coal-tar dyes, was discovered by Mr. Perkin while he was endeavouring to form artificial quinine.

PLANTERS ON INDIAN OFFICIALDOM.

[COMMUNICATED.]

We cannot in regard to the Indian C. S. expect to find, among the rising members of that envied profession, so many of the class that once almost exclusively filled its ranks, and had, by so doing, become patrician in the days of the East India Company, when the son followed the father, and had a family name and prestige to uphold. No, here, as in England, the plebeian and the patrician have now to elbow each other in the race; and as the plebeians of England greatly out-number the patricians, what wonder is there that, in these days of cheap (almost free) education, the number of the former in the Civil Service, the army, the D. P. W. and other Government services, should exceed that of the latter?

It is not with the origin but with the conduct of officials that we have now to do: the former consideration is only so far necessary as it tends to throw some light upon the latter. We all know Shakespeare's lament over the tricks of the man clothed in a little brief authority. More sad (or more amusing, according to the temper of the observer) are the airs of our Government servants who find themselves hoisted into positions of wealth, honour, and power, far above the level from which they have emerged. Now, if our officials choose to tolerate the assumption of almost divine honours by the C. S., and, if there were no other Europeans besides Government servants in the country, no one would have any just cause for complaint. As, however, it happens that, in many dependencies, remote though they may be, as for example, the Provinces of Assam, Cachar and Sylhet, of Mysore, Coorg, and Travancore—some directly under our rule, others in the hands of their own native Princes, but under British surveillance—the European planting community is a large one, and the amount of capital invested in tea, coffee, and cinchona, considerable; these large and important bodies of men, who are at present powerless owing to their disunion, are liable to, at any time, become powerful and dangerous on account of their strength, should common injustice and official arrogance impel them to unite and make common cause against their persecutors and insulters. The individuals composing these bodies of men differ as much, *inter se*, as regards origin as do the individuals composing the ranks of the Civil Service or the army; some are patrician, others are plebeian—very much so in a few cases. They are at present disunited through rivalry in business and class jealousy. If, however, jealousy is not sufficient to keep asunder rival aspirants for prizes in the ranks of the C. S., the army, the D. P. W. and other Government services, when one of their number has been met (it matters not with what justice) with opposition by a planter, the time may, perhaps, come when the scales of ignorance of their own strength (induced by the malady of personal jealousy) shall drop from the eyes of the planters and other non-officials, and they will make common cause against the aggressive insolence of certain Government servants. These are paid (and handsomely paid) for doing *their* work, just as all other loyal subjects of Her Majesty, whether European or native, have to do their work; but officials are not paid to use or abuse the official position with which Her Majesty's Government has entrusted them, and by so entrusting has honored them, for the purpose of insulting and obstructing non-official Europeans whenever the opportunity may occur to them to show their power before their native subordinates.

Have we not all seen the light in which Colonel Bumblebeaks, the Deputy Commissioner, regards the planter or other outsider whose income is say between R200 and R500 per mensem, while Colonel B. draws a large salary for—what? Now many a planter is of a family better than that of Col. B., and one that at home occupies a higher social position than his; but here the planter draws a small pittance, and Col. B., thinks himself entitled to assume superiority over him because he draws huge pay for doing—what? He knows, we imagine, though others might find it more difficult to explain.

Should the planter not care to call upon Col. B., he will find upon any occasion, when business may require his presence in the Deputy Commissioner's kachcheri, that the official cannot forgive the slight; should he call, he will be treated with half-contemptuous grudging civility, though the almighty man will not scruple, upon occasion, to condescend to sponge upon the planter's resources by requesting the loan of his boat, horse, or elephant.

We all know Mr. Brown, the greengrocer's son, who is now Assistant Magistrate. What a pet he is among the ladies, and how mammas with marriageable daughters vie with one another in doing him homage! The result is that Brown, who was not a bad fellow at 20, and with whom we formerly passed some pleasant days, has become an insufferably conceited young puppy, in place of the quiet (almost timid and retiring) man that he used to be while yet at his crammer's, now betrays his real origin; and, under the illusion that all his utterances, of whatever nature, are the *crême de la crême* of wit, occasionally gives vent to veiled vulgarisms and scandalous *doubles entendres*, which his innocent appreciators applaud simply because they do not understand them, but which almost cause his male auditors to blush for their sex.

The planting community has much reason to complain, in many districts, not only of the arrogance and assumption of Indian officials, but also of the injustice which the latter, through their ignorance o

law, often commit. There have been flagrant instances of this in Assam—that far-off corner of our Imperial dependency, devoted to the consumption of opium, the cultivation of tea, and the growth of that interesting, if worthless and expensive cereal, viz. *official wild oats*—that region which stands "facile princeps" in the virulence of its mosquitoes, the drowsiness of its Public Works Department, and the marvellous renderings of the law, provoked by the maddening irritation of the Theacultural red rag. This province is commonly supposed to be regarded by the Supreme Government in the light of a useful penal settlement for the banishment of certain troublesome officials, whose eccentricities would not be tolerated in a more civilized region. This supposition is the more tenable since it is on a par with the fostering care and sympathetic consideration which the tea industry has at all times—though undeservedly—enjoyed at the hands of the paternal Government.

Truly the Assam planter has much to be thankful for! Struggling to maintain the existence of a fickle and precarious industry, often poorly paid and generally unable to obtain more than the bare necessaries of life; oppressed by mosquitoes, and an adverse climate; worried by agents, superiors, subordinates, and last, but not least, by the unspeakable cooly; deprived in many cases of ladies' society; cut off from the ordinary enjoyments of a social life; and denied the justice, which in England, and wherever else England's Queen holds sway, he would not ask in vain. This is the crowning punishment for his presumption in going to Assam, and so securing their banishment from Bengal of the officials before alluded to—who, but for him, would have had to be provided for in other remote corners were they might

"Blush unseen
And waste their sweetness on the desert air."

We gladly admit some districts in Assam have reason for self-congratulation upon the ability of their Government officials, but notable instances of a very opposite character are by no means uncommon. We have seen dire confusion in the ranks of Bumbledom effected by the advent to a district (whose Deputy Commissioner appeared to imagine that a knowledge of law was quite superfluous, and that every utterance of his own sweet will was *ipso facto* law) of a planter who had formerly served her Majesty in a magisterial capacity, and *had* taken the trouble to study the law while engaged in its administration. —*Madras Times.*

BRIGHTENING PROSPECTS FOR COFFEE

COFFEE TRADE IN THE UNITED STATES IN 1881.

The following condensed summary of the coffee trade of the United States for the calendar year 1881, compared with previous years, is from the columns of the New York *Shipping List* of January 21st:—

GENERAL STATEMENT.

	Bags, etc.	Total tons.
Receipts in the United States in 1881 ...	3,615,649	205,354
Add stock January 1st, 1881	417,902	19,353
Total supply	4,033,551	224,707
Deduct exports by sea and shipments inland to Canada in 1881	313,192	21,238
	3,720,359	203,469
Deduct stock January 1st, 1882... ...	368,293	18,172
Taken for consumption in 1881	3,352,066	185,297
Taken for consumption in 1880	3,102,338	169,416
Increase in 1881	249,728	15,881

		Pkgs.
Receipts in United States in 1880		3,297,029
Add stock, January 1st, 1880		404,490
Total supply		3,701,519
Deduct exports in 1880	181,279	
And stock, January 1st, 1881	417,902	
		599,181
Taken for consumption in 1880 ...	... pkgs.	3,102,338
Weighing	... tons.	169,416
Consumption of 1879		179,241
Decrease in 1880 ...	... tons.	9,825
		Pkgs.
Receipts in United States in 1879		3,510,389
Add stock, January 1st, 1879		212,278
Total supply		3,722,667
Deduct exports in 1879	135,796	
And stock, January 1st, 1880	404,490	
		540,286
Taken for consumption in 1879...	... pkgs.	3,182,381
Weighing	... tons.	179,241
Consumption of 1878		142,372
Increase in 1879...		36,869

It would appear from the above figures that the *consumption* of coffee in the United States from 1878 to 1881 has been :—

In 1878	... 142,372	tons.
,, 1879	... 179,241	,,
,, 1880	... 169,416	,,
,, 1881	... 185,297	,,

The increase in 1879 over 1878 was 36,869 tons; then came a decrease in 1880 of 9,825 tons compared with 1879, but 1881 shewed an increase of 15,881 tons over 1880. The average for the four years would be 170,000 tons; but, as the figures for 1878 were so much lower than those of the succeeding years, a better average will be obtained from the past three years. This is 178,000 tons, or 3,560,000 cwt. But, as the increase of 1881 over 1878 is no less than 43,000 tons, or at the average of about 11,000 tons per annum, and as the population is increasing at such an enormous rate, we feel justified in estimating the consumption of 1882 at a figure closely approaching 200,000 tons, or 4,000,000 cwt. If the increased consumption of coffee follows the proportion of increase to the population, we may venture to predict the following figures :—

U. S. consumption of coffee	1883 ...	215,000	tons.
,, ,, ,,	1884 ...	235,000	,,
,, ,, ,,	1885 ...	260,000	,,
,, ,, ,,	1886 ...	290,000	,,
,, ,, ,,	1887 ...	325,000	,,

or 6,500,000 cwt., equal to the present Brazil crop, which is not likely to be largely increased. The consumption of coffee, present and prospective, in the great Western Republic, is the keystone of hope for the coffee enterprize. If emigration from Europe continues at the present rate to the United States, our estimates of consumption will probably be largely exceeded.

THE PEOPLE'S COFFEE ROASTER.

We give prominence to this further communication on a very practical and important topic; without doubt the coffee roaster required should be automatic, and everything should done that can be done to induce the English people to roast coffee for themselves, seeing how they are poisoned at present by grocers. With our wealth of mechanical skill in Ceylon, as displayed by patents and new machines, big and little, for years past, why should the coffee roaster of the future not be invented here? A wide sale might be anticipated for a suitable article.

The idea of offering a prize for a cheap and effective machine to be independent of the kitchen fire—fed at an infinitesimal cost by oil now in general use and admitting of the flames being lighted and extinguished in a moment—seems to be a good one but to make it perfect and to permit of coffee having an equal chance with tea (especially with the working classes, whose time is their money) it MUST BE SO ARRANGED AS TO WORK AUTOMATICALLY.

Just as, years ago, cheap, old-fashioned clocks, wound up and kept going for 24 hours by long cords and weights, were hung on cottage walls, in like manner the "Universal Coffee Roaster" must be capable of being placed on the ground in some corner of the kitchen, racket wheels and pulleys, cords and weights so arranged that when the latter were drawn up to a certain height their momentum would prove sufficient to set and keep *steadily in motion* the revolving cylinder below, say for the space of half-an-hour or whatever time it takes to thoroughly roast coffee. Worked in this fashion the machine could not well fail to prove a success, for the housewife would soon learn to what height the weights should be drawn to admit of the coffee being roasted (*without further attention*) to the required chestnut hue. A few minutes more or less would probably make a difference in the flavour, but by the method here indicated the exact time required would soon be discovered, and then there would be no difficulty in making every succeeding roasting precisely the same. Heated by either oil or gas there would be an end to the uncertainties and troubles neecssarily attendant on roasters placed on the fire and turned by hand. The addition of a very *small* piece of butter to the beans when they were placed on the cylinder and a teaspoonful of sugar just before the cylinder performed its final revolution would make the operation an assured success.

P.S.—Good, sound, green coffee, not less than six months old (12 months would be better), should be purchased, and the cylinder should, of course, not be more than about half filled; for in the roasting the beans swell *very considerably*—fully one-third of their original bulk, if I remember correctly. Of course a powerful spring would be preferable to pulleys and weights if the cost would not be prohibitive.

A SUBSTITUTE FOR CINCHONA.—With reference to the extract from a home paper on this subject, we feel that persons interested in cinchona plantations need not prepare to cut them down for firewood. Our readers will observe that art has never yet succeeded in the formation of a vegetable alkaloid, and, although it may be possible that M. Maumené has been in some measure successful, the probability is that some element may be wanting, just as in the production of artificial beef. In any case the almost certainty is that the artificial product cannot compete in price with that formed in nature's laboratory and extracted by the Howards and Whiffens and other quinologists of our day.

THE PIONEER TEA STEAMERS may be looked for here in the course of a few days, the Stirling Castle, although she has not been the first to get away, being here probably about the same time as the Glenfruin, which stole a march upon her, and, probably somewhat owing to the fact that she was much sooner filled, got away with the first teas from Hankow.—*Straits Times.*

COFFEE ADULTERATION.—An estate proprietor writes:—"Ceylon should show its appreciation of Messrs. Pasteur's and Dickson's adulteration exertions, and the least to be done is to give them thanks from all public bodies in the island, including the Legislative Council. They are the first to get any satisfaction as to our great grievance, which is of very old standing; it was old when Dickson was Consul, and that 's a long time ago.

A GOOD IDEA.—A correspondent writes:—What do you think of the suggestion of a halfpenny or penny subscription by total abstainers at home for the best and cheapest working man's coffee roaster? It would total up to £1,000-3,000, and such a prize would bring the brains of *everyone* (even stars of engineers) to bear. It is the great desideratum, as drink is the greatest *curse* of the age. Such a prize would also allow of the *best and cheapest coffee pot* as well.

COFFEE.—Statistics show that over 1,500,000 operatives are employed in the manufacture of cotton goods in the principal countries of the world. Of these 480,000 are employed in Great Britain. France follows, with 210,000, and the other countries, in order of precedence, are the United States, Russia, Germany and India. With regard, however, to the annual value of cotton goods produced, the United States comes second, with about half the value of the production of Great Britain; and Germany and Russia follow.—*Rio News.*

A MINIATURE GARDEN.—*La Nature* gives the following instructions for raising a live bouquet as a pretty ornament for a room:—Get a cheap sponge—the bigger the better—and, having dipped it in warm water, squeeze out half the water. Put into the holes seeds of millet, barley, purslane, red clover, grasses, &c., and in general any seeds germinating easily, and that will give a considerable variety of colours. Place the sponge thus prepared on a vase, or hang it in a window facing the sun. Sprinkle it with water every morning during a week. The sponge will soon be covered with vegetation.—*Chemist and Druggist.*

DRIED TURTLE FLESH AND BECHE-DE-MER are thus noticed in an article on Colonial Fishersies in the *Colonies & India*:—

A "turtle pen" in the West Indies is by no means a bad investment, and the wonder is that, with the demand for these reptiles which exists, the colonists do not do more in this direction. The drying of turtle flesh—after the manner of the "jerked beef"—is an industry which the tastes of London aldermen have, perhaps unwittingly, created. A still more curious industry is that of catching and drying the celebrated trepang or *bêche-de-mer*, of the South Seas and the East. In the Malay Peninsula and Archipelago, in Fiji, in Queensland, all over the Southern Pacific, abounds a species of sea-slug, scientifically known as *holothuria*, a somewhat hairy, slimy, black or brown creature, an inch or two wide by five or six inches long, which the natives catch, dry in the sun, and pack off to China at great profit. As French frogs have made their way into the London market, we may one day see the *bêche-de-mer* imported and consumed here—and connoisseurs say that Londoners display very bad taste in not having introduced this luxury.

Correspondence.

To the Editor of the Ceylon Observer.

CEARÁ RUBBER: TAPPING THREE TREES 18 MONTHS OLD.

31st May 1882.

DEAR SIR,—I send by this post an egg of Ceará rubber milk, which was taken by myself and a cooly within 1-30 to 3-40 p. m. on Gondeennawa estate in Nawalapitiya. My cooly Muttusamy, says that they will have a luck in feature in collecting rubbers under green shade; it seems that coolies are very fond of collecting rubbers.

I think within a few years our old Ceylon will beat Ceará in its rubber. So, dear editor, please let us know your remarks on this egg of rubber and oblige, yours obediently, J. P. ABRAHAM.

[The "egg of rubber" is as tough and elastic as could be wished, and the colour seems good. There is some moisture on the surface, which has a powerfully acid smell. We shall send the specimen to some one better able to judge of its quality. Meantime we hope Muttusamy cooly may turn out a true prophet as to the "feature" of Ceylon in regard to rubber. So many electric telegraph cables are being laid that a large demand is likely to continue for the gum.—ED.]

CINCHONA BARKING MACHINES.

No. I.

Lindula, 1st June 1882.

DEAR SIR,—In justice to Mr. de Caen, I must say that, when I wrote my first letter, I had only passed officinalis twigs through his machine, and that, when I and four coolies picked out the *biggest branches of succirubra*, we managed to get 12½ lb. of wet bark in about half-an-hour, or an average of 300 lb. per day for five coolies: but in justice to myself too I may say that, had I known that the machine was only meant to bark *selected succirubra branches*, I should either have not invested in one or have kept a "calm sough," merely muttering to myself: "*Le jeu ne vaut pas la chandelle.*"—Yours faithfully, KÁROLY FÜRDÖ.

No. II.

Mousa Ella, Lindula, June 1st, 1882.

DEAR SIR,—As there seems to be a general desire to have some reliable record of the amount of work done by the various cinchona-quilling machines, I beg to offer my experience of Rae's little machine, made by Messrs. Walker & Greig, Tillicoultry.

I have been using one of the above for nearly a month, and during that time have put it to some severe tests with dying trees, and otherwise, and must say I have every reason to be satisfied with it.

At present it is employed on officinalis branches and suckers (varying from ¼ to 1½ inch in diameter), and under these circumstances I obtain 10 lb. of bark per cooly per working hour, making 400 lb. per day (of 10 hours) from the 4 coolies employed at the machine.

The sample of quill obtained by using this little "barker" is really excellent, and the percentage crushed is very small indeed.

The peculiar construction of the rollers allows of the bark of young trees 5 feet or so long being removed in 2 long strips without a single break, and that in much less time than it takes to write it.

The whole machine can be readily transported from one place to another by one cooly.—Yours faithfully, T. Mc.L.

No. III.

Deltota, June 2nd, 1882.

DEAR SIR,—My experience of Mr. de Caen's cinchona machine is similar to that of your other correspondents. I purchased one of his machines, believing it would be a profitable investment to the estate, but I only used it one day, the coolies bringing in the evening 125 lb., and they were very tired and had blistered hands as well. The bark was very inferior to that obtained by other processes, and the loss by dust was considerable in the drying. There was besides a great deal of bark jammed in the wood, which would have cost a great deal to get out. I should be glad if Mr. de Caen would send over 5 coolies to show me how to use the machine. As this estate is only 14 miles from his residence, they can easily come, and, provided they do the advertized task between 6 a. m. and 4 p. m.,* I will give them a bonus of R2 each. Otherwise I think he should refund the money, my paying the cost of repainting the machine. Two coolies can easily carry my one.—Yours faithfully, R. P. H.

CINCHONA SHIPMENTS TO THE UNITED STATES.

SIR,—The Ceylon United States Consul writes to a local firm with regard to cinchona as follows:—"I note that cinchona is imported into the United States free of duty, if direct from the producing country; and, I judge from a recent decision of the United States Supreme Court, free also from differential duty." The amount shipped to New York since 1st July 1881 to present date (5th June 1882) is 62,434 lb. most of which went via England on through invoice.—Yours truly, CINCHONA.

[What are the Yankees doing? Surely a million lb. ought to be taken by direct shipments.—ED.]

INSECT ENEMY OF CINCHONA.

3rd June 1882.

DEAR SIR,—I send by this post several cin. offic. leaves infected with a small insect. Can you inform me through the medium of the *Observer* what they are, and if they are likely to do much damage?

When young the insects appear to be quite white, but in a few days they change rapidly and become perfectly black.

You will note that several of the leaves are perforated with holes. Whether these are done by these insects I am not yet in a position to state, but as I have never yet been able to find any other insect or caterpillar on the trees infected I think they must be.—Yours faithfully, X. Y. Z.

[The insect is a *Thrips*, belonging to the small order *Thysanoptera*. It is described in "Garden Pests and their Eradication," page 63. Westwood says:—"These insects are found upon various plants, sometimes swarming in immense profusion. They feed upon the juices of plants, and are often extremely injurious, the leaves upon which they reside being marked all over with small decayed patches." In the case in question, it is doubtful whether the remedies given in "Garden Pests" could be advantageously applied. Their cost would probably exceed the loss sustained through the damage done by the insect—unless the trees that have been attacked are few in number.—ED.]

JAK TREES AS SHADE FOR COFFEE.

To the Editor of the Tropical Agriculturist.

DEAR SIR,—I should be obliged if you will allow me a few words in answer to your correspondent

* I stipulate that all the bark must be taken off, and allowance of two per cent made.

"P. T. L." with regard to the advisability of planting out jak trees as shade to coffee.

The opinions I hold are not by any means original, but are common to most Coorg planters. In Coorg, especially in the south, shade is an essential to coffee, and, necessarily, the great thing is to find a tree which, on account of its loftiness or size of leaf, is most beneficial to that plant. Opinions during the course of years have undergone many changes. For instance, not very long ago, THE great shade was held to be "charcoal tree;" so much so that it was planted out in the coffee systematically. Now, however, it has quite lost favour, and is on many estates all being rung out. This is by no means the only example, many trees being considered A1, and after the lapse of a few months very much the reverse.

Latterly, however, the tree in question, the jak, has stepped to the fore, so much so that most estates, if the plants are available, put them out in the coffee rows about ten trees apart. I myself have seen invariably splendid coffee under jak, not, as "P. T. L." has, all foliage and no crop, but the reverse. The great thing in shade of all kinds is to keep it when young well lopped up, say 20 ft. without a branch, and, I think, if "P. T. L." will always keep his jaks well trimmed, they will not disappoint him. The argument your correspondent urges about "the constantly falling leaves" doing damage to drains by stopping them up I cannot refute, as here we have few or no no drains.* the land being flat; the more leaves that fall the better always an addition to the soil. I should not, however, think that the leaves could do much harm; at any rate no more than other trees that shed their leaves and certainly not so much as prunings.

Natives also are very fond of jak, the stomach having a great deal, I dare say, to do with it; but I have seen cardamoms growing luxuriantly and cropping well in a clearing, the majority of the shade being jak. "P. T. L." seems to infer that it is a surface feeder by his paragraph beginning "but after that period (*i. e.* two years) has become incorporated with the past and their roots begin to know their way about, look our for your coffee," etc. That this is incorrect, to say the least of it, must be well known to those who have planted it out, it being a most difficult tree to transplant, owing to the tremendous length its tap root attains, even after a few months' growth. A great thing also in its favour is that it nearly always looks and is healthy: you seldom see a blighted jak.—Yours faithfully, L. I. P.

COCOA AND INSECT ENEMIES.

Colombo, 8th June 1882.

SIR,—Allow me, through the medium of your paper to enquire from cocoa planters, if they have ever tried a handful or two of powdered castor cake mixed with the soil prepared to receive the cocoa plant: if so, if it is a successful remedy against the attacks of white ants.

Is jakwood sawdust placed round the stem of the plant also effectual in keeping off white ants? These and other insects seem to be the greatest difficulty we have to contend with in the low-country in pushing this product forward.

Again; is it necessary to keep the land planted with cocoa throughly weeded, and free from all grass and quite bare—and to treat it in the same way as you do coffee?

Any suggestions gained from practical experience will be thankfully received by

COCOA PLANTERS.

* The climate is a dry one, and the experience is very different from the heavy rainfall and wash experienced in Ceylon.—ED.

PLANTING IN MYSORE:—JAK SHADE FOR COFFEE; SHADE NO PREVENTIVE OF LEAF-FUNGUS; THE NALKNAAD COFFEE; DENSE SHADE FOR CARDAMOMS; CINCHONA CULTIVATION.

Igoor, Munzerabad.

The Editor of the "Tropical Agriculturist."

DEAR SIR,—I notice several subjects of interest in your last issue that seem to require further ventilating, and so I am induced to offer you a few remarks thereon should you think them worthy of insertion in your ensuing number.

Your correspondent, "P. T. L.," I conclude, has never wandered out into this part of the world, for in Mysore the jak tree is considered about the very best tree where shade for coffee is necessary. Under its protection and for some little distance around the coffee is almost invariably more vigorous than elsewhere, especially in seasons of great drought, and gives, as a rule, fair average crops, and frequently bumper ones. Unless there is an excess of them together, scarcely a planter here would cut one down in preference to any other caste of tree. Even in neglected and unmanured portions of poorly cultivated estates, a distinct ring of healthy-looking coffee in the midst of a sea of shuck-plants is generally observable at all seasons, and more peculiarly so, the older the coffee is; to my own actual knowledge, this is the case up to the age of 40 years. The only coffee I have seen where it has looked somewhat less promising than under other shade has been now and then where the old coffee has been grubbed up and replanted with Coorg plants; but then, these, I am convinced, thrive best for the first three or four years without any shade at all, and the dense foliage of the jak retards their growth.

I quite agree with the notion that has lately been receiving the attention of Ceylon planters, namely, planting out a new variety of coffee plant more capable of resisting the *effects* of leaf-disease; but I am inclined to think that the Nalknaad seed is usurping a credit that is not at present its ascertained due, and is wearing the spurs won by the seed from coffee generally grown in Coorg. I think I am correct in stating that, until some 11 years since, no seed coffee for sowing had been exported from Coorg, about which time my late brother and myself were so thoroughly satisfied of the much greater hardiness of the ordinary, then called horizontals, compared with the chicks, an opportunity of observing the two varieties growing intermixed having occurred, we not only imported some seed of the former, but preached up its good qualities, that gradually each planter in Mysore became convinced, and no one dreams now of putting down any but Coorg seed. The seed that has been so brought in has grown into the most vigorous plants, and it has been the valuable means of renewing our worn-out properties (as far as the coffee trees went), and actually saving many of us from absolute ruin. The Nalknaad so-called variety, as far as I am aware, has not been cultivated much, if at all, outside its own native area, until within at most the last three or four years—a not sufficiently long period to give plants of an age as yet, to determine whether, *when in full bearing*, they are more capable of resisting the ravages of *Hemileia* than the rest of the coffee grown in Coorg. I am inclined to suppose that its immunity from it in Nalknaad itself is, perhaps, more due to some advantages of locality or treatment than from its being a different variety, and that, when removed from those specially favourable circumstances, it will prove no more disease-resisting than such seed as we have been growing for nearly a dozen years and picked from the estates of Messrs. Mangles, J. P.

Hunt, and one or two other gentlemen. Plants grown from Coorg seed are certainly not free from leaf-disease on any estates that I have had the opportunity of observing it, but then on the only estate on which I have seen Nalknaad plants growing they were literally eaten up with *Hemileia* before they were a year out in the field. These plants show no distinctive shape in them different to other Coorg plants, and a neighbour of mine reports the same of his Nalknaad plants. I don't doubt the coffee at Nalknaad itself being all that is claimed for it, but I don't think we have sufficient data to go upon that it will reproduce the same much-desired results elsewhere with any certainty. I think you must attach more importance than Mr. Middleton intended to his advocacy of the Nalknaad variety, as I do not think he has had sufficient opportunity of judging of its merits personally, or in comparison with other Coorg plants, as his plants, I think, are scarcely a fair criterion of resisting leaf-disease, his rainfall being so heavy, and, as far as I am aware, they are planted amongst cardamoms where very dense shade (too dense even with a very much lighter rainfall for coffee) is absolutely necessary: they have never yielded a fair crop, and I do not think it can be a fair test of the resisting powers of coffee from leaf-disease, unless it has borne a good crop at least, this being particularly the case with young Coorg plants. I imagine most Mysore planters must have stared, when they read the statement that Mr. Elliott's estates had been free of leaf-disease in consequence of shade! It is the first time I have heard of such a happy state of things, and it would be news that would travel far and wide. All planters here (I must except Mr. Elliott, I suppose) will admit that shade is no preventive of fungus, as a proof of which I need not mention the native gardens, which as a rule are planted under the densest primeval forest, and undoubtedly they have suffered worse than the European gardens, which are comparatively in the open. A very large percentage of the former were utterly ruined by it!

I observe that *C. ledgeriana* seedlings are supposed to die off from the effects of a minute snail. I could not understand the cause; tried more and less watering without avail. A friend passing through advised sprinkling them with flowers of sulphur out of a pepper pot at intervals. I am trying it, but have not yet had time to decide upon its merits, but I can say that apparently it does them no harm, which is of some little importance anyhow.

Liberians are not much in favor here, and certainly as a rule they don't appear very promising. I have, however, 4 plants here brought out as seedlings from bulbs late in 1875 and are planted in open land and not jungle and have had very hard treatment. Last year they gave me about 1,700 beans, and I have this season already picked over 2,000 beans, and have as many more I imagine on the trees. They are very handsome plants, closely branched, but their progeny do not promise the same, instead showing a disinclination to throw out primaries. They were loaded with *Hemileia* the first year, but have not had a trace of it since.

I find that Ledger seed comes up almost without a failure when it has nothing but the finest (nearly as fine as in an hour-glass) river sand *over* it, but invariably I have had very heavy failures when earth has been mixed with the sand. In both cases merely sufficient to cover the seed was sprinkled over, and watered with a hair brush lightly. I remember seeing the fine coffee adjacent to Mr. Mann's bungalow in Mercara about a dozen years ago, and was told that the extraordinary results in the way of crop were due to manuring and irrigation, no mention was made of the fact of its being Nalknaad seed.

My remarks have extended themselves into such a long letter that I fear you will be inclined to put it where many a more important and interesting one has gone ere this, namely the waste-paper basket, as a hint not to offend again.—Yours faithfully,

MAHSEER.

[Our correspondent gives us interesting and useful information: the Liberian coffee plant clearly requires a moister climate and lower elevation than are found in Mysore or Coorg.—ED.]

"THE GARDENS OF THE SUN" AND TROPICAL AGRICULTURE.

DEAR SIR,—I send you some extracts, which you may think worth inserting, taken from "The Gardens of the Sun," by F. W. Burbidge, the great botanist. The book is a record of his travels in Borneo and the Sulu Archipelago, and is as interesting as all such books are: but one very noticeable peculiarity of the author's style is his invariable adherence to Cardinal Wolsey's motto of *ego et rex meus*. In every instance it is "I and Mr. Veitch," "I and Mr. Cowie," &c. Otherwise he says his say well.—Yours faithfully,

KÁROLY FÜRDÖ.

ANTS.—"The species of ants vary much in size. One is a tiny red fellow, but little larger than a cheese-mite, and scarcely visible: others are black, their bodies being an inch in length." (P. 126.) (This does not quite come up to the Chinese ant, one foot long!—K. F.)

SAGO.—"We stayed at one little sago station, where the natives were preparing the raw product. The process is very simple. The trees are cut down just as they attain maturity, the time being known by the production of the branched inflorescence. The leaves are removed, and then the trunks, which are ten to fifteen feet long, and as thick as a man's body, are split longitudinally into two halves. A man then cuts out the pith, with which the whole centre of the trunk is filled. This requires some skill. The implement employed for the purpose is an axe, formed by a bamboo stem, fixed in a stout wooden handle, and lashed with rattan. By repeated strokes of this instrument the pith and fibres are scooped out in thin layers, care being taken to cut it out as free from lumps as possible. The pulped pith is then carried in baskets to a washing apparatus. This consists of a rudely constructed vat, elevated on piles, beside a river or brook whence fresh and clean water is plentifully obtainable. From the vat a spout conducts the water into a trough below. The bottom of the vat is covered with a mat or bark-strainer. The pith is now placed in the vat, and trodden, water being occasionally poured over it during the progress, and the result is that the fine sago starch is washed through, and settles in the bottom of the trough below, the coarse particles and other impurities being retained by the strainers, at the bottom of the treading-vat. After the fine sago has been allowed time to settle in the trough, the water is run off, and the white pretty-looking mass below is packed up in bags, and sold to the Chinamen, by whom it is again washed and dried, previous to its being shipped to the Singapore market. Two species of sago palm grow here, forming stout-stemmed trees, 30 or 40 feet in height. They are readily distinguished by the one having smooth bases to the sheathing leaf-stalks, while the other has the leaf-sheaths set with stout black spine. The smooth variety is most abundant. The dried leaf-sheaths of this palm are utilized in the manufacture of neat baskets, being neatly sown together with strips of rattan, and fitted with lids. Rattans are much used in house building, the largest timbers being secured by their aid only." (P. 176.)

LEAF-DISEASE, &C.—"I saw coffee bushes growing apparently wild around the little farm-houses on the cool hill-sides (in Sulu); especially on Bu'at Dahan, which I ascended a few days after our return from Bu'at Timantangis, and every leaf was fresh and green without a trace of the leaf fungus, which of late years has proved so hurtful in Ceylon. The cocoa yielding Theobroma does equally well and fruits freely, forming indeed what may

be called the national beverage in Sulu. Excellent tobacco is grown here, and this, if skilfully prepared, would furnish cigars equal to those of Manilla. Cotton would do well, and the highest red land on the mountains, rich as it is with ages of forest debris, might be advantageously planted with coffee or other crops." (P. 221.)

MODE OF TERRACING.—"The soil [near Kina Balu in Borneo] is a reddish friable loam thickly sprinkled with large sand-stone boulders and stones: while in the lower plains and valleys is a deep black deposit, which under irrigation yields splendid crops of rice. Under European protection and management, aided by systematic Chinese cooly labour, the virgin tracts on these hill-ranges might be worked with advantage in the production of coffee and cinchona. Once fairly started, and with improved roads, this district would possess many attractions, not the least being a comparatively cool and salubrious climate. At elevations of 3,000 to 5,000 feet a cool bracing air is readily obtainable, indeed, as suggested by Mr. Low, the Marie Parie spur would form a capital site for a sanatorium of the utmost value to Europeans. At higher elevations a really cool climate, almost European, in fact, is obtainable. To bring this fertile district into cultivation and to form anything like good roads, however, would be a task Herculean, and one only to be accomplished by an immense expenditure of labour and capital. The system employed by the natives in clearing their new farms is to fell the trees and then to burn them during the dry season. The old stumps are left, and to prevent the rich earth and forest *debris* from being washed away by heavy rains, logs are laid against these horizontally all down the steep shoulders of the spurs." (P. 289.)

MR. DOBREE.—"We were surprised by meeting a young Labuan man—whom I had formerly employed * * * and from him I heard that Mr. Pretyman, accompanied by Mr. Dobree, a Ceylon coffee-planter, were following, and that their object was to proceed to 'Kina Balu' in search of land suitable for coffee culture. A few minutes later we met them and had luncheon together on the dry stones of an old river course. An answer to Mr. Dobree's inquiries I told him what I have seen of the country, of the large extent either actually under cultivation by the Dusun or lying fallow as jungle, and that virgin soil in large tracts would only be obtainable by felling the primæval forests on the enormous spurs of Kina Balu itself." (P. 298.)

"About 4 o'clock we were surprised at the return of Mr. Dobree and Mr. Pretyman, who had proceeded no further than the hill just above Sincroup. The Chinese cook, of course, received orders to augment his food supply, and we spent a agreeable evenings Mr. Dobree showed us the skin of a young rhinoceros which he had shot in the mudpool near the Sagaliad river, about 20 miles from Sandakan. The lower horn was three inches in length, the upper one only just growing." (P. 301.)

HYBRID.—"We were successful in finding all the large species of nephenthes in one locality on the mountain for the first time, and in addition a distinct variety of *N. Edwardsiana* with shorter thick-winged pitchers, which it is possible may prove to be a natural hybrid between *N. Edwardsiana* and *N. Villosa*." (P. 344.) [So this well-known botanist believes in hybrids, at all events!—K. F.]

CONSUMPTION OF CHINA TEA IN CEYLON: GREAT DECREASE IN THE PAST THREE YEARS.—The figures we published shewing the consumption of imported tea in Ceylon prove that, at length, the island-grown product is finding favour in its own country. Up to 1878, the average annual consumption of imported tea was about 71,000 lb., and perhaps Ceylon-grown tea made up the round 100,000 lb. For the past three years the average has dropped to a little over 31,000 of imported tea, and we should hope that Ceylon tea has not only filled the void, but that at least 100,000 lb. of Ceylon tea was consumed in 1881 in addition to the 31,865 lb. of foreign. As native coffee has so largely disappeared a taste for tea as a substitute ought to be cultivated amongst the natives, until the consumption of "the leaf which cheers but not inebriates" equals 1 lb. per caput of the population. That would be 2¾ millions of lb., instead of a little over 100,000 lb. now. The time for such a result is doubtless coming as well as for an export equal to ten and twenty fold the quantity locally consumed.

GEMS.—In the year 1871 precious stones to the value of $2,346,732 were imported into the United States, of which $2,283,350 were received in New York. In 1880 the value of these imports was $6,698,488, New York taking $6,294,392. Last year gems to the value of $8,332,511 passed through the custom house, $7,884,739 being for the New York market.—*Rio News.*

THE TEA COMPETITION between India and China is progressing apace. As far as regards the United Kingdom, the imports in four years from the former country increased by 20,500,000 lb., while those of the latter decreased, in the same period, 9,000,000 lbs.! In seven months last year India exported 185,000 lb. to America, and about half-a-million pounds of tea to Australia. Considering that the growth of the former trade is altogether recent, and the latter only two years old, the figures mentioned are, to say the least, surprizing.—*Friend of India.*

RAIN AND BLOSSOMS.—"Advance" writes:—"Many a well-known proprietor approves of what I wrote *re* untimely rain in January, February and March on the Kandy side. He said all his letters and reports gave that as the reason for short crops this year. Can *you* not give the figures in parallel columns? and shew daily comparison for the 3 months." It is not an easy matter giving the figures for a series of years for three or four months for a *series of stations*. However we have selected Dimbula, Dikoya, Maskeliya, Pussellawa, Nawalapitya, Maturata, Kandy, Rangalla and a Matale stations, and, with the assistance of the Surveyor-General's Department, we hope to make up such a table as is required at our hands.

THE PRODUCTION OF INDIGO AND QUININE FROM COAL TAR.—A correspondent has been good enough to send us the *Journal of Gas-lighting*, which is full of articles shewing how little chance the electric light has in competition with gas light. Amongst miscellaneous matter we find the following, which need not, we think alarm indigo or cinchona planters:—

The production of artificial indigo from coal-tar products will probably be extended, under a recent patent of the "Badische-Anilian und Soda-fabrik," where the original process of Professor Baeyer is worked. The fifth step in this process consisted in the preparation of a compound known as orthonitro-phenylpropiolic acid. By the new patented process certain bye-products obtained from this acid are worked as sources of indigo. The action of alkaline-reducing agents, such as ammonium sulphide, or the ethyl salt of this acid, produces ethylic indogenate. By saponification of this salt a further product called indogenic acid is obtained, which easily gives off carbonic anhydride, either by boiling in aqueous solutions or by heating to its melting point. The result of this is the production of indogen, an oily liquid, showing yellow-green fluorescence. Any one of these substances—ethylic indogenate, indogenic acid, or indogen—readily yields indigo blue by the action of weak acids or alkalies when freely exposed to the air without heating. Although the cost of artificial indigo is still above that of the natural dye, it is for some purposes more economical in use, because of its freedom from waste, and a large trade is already done in the product as prepared in Germany. With regard to the other remarkable derivative from coal tar—artificial quinine—it is stated that the commercial production of this invaluable drug is no longer doubtful. Professor Skraup, of Vienna, and a French chemist, claim to have succeeded in producing pure chinoline—a substance which has long been a known derivative of quinine—and which may prove to be its medicinal equivalent. Pathological experiments will have to be made on an extensive scale before the confidence of the medical profession in the new alkaloid can be assured. This is now being done, and Professor Morton is reported to have declared that, should the value of the artificial drug be established, the community will be greatly benefited, since the product in question can be made for about 4s a pound, while sulphate of quinine is worth about 16s per ounce.

THE SCOTTISH ARBORICULTURAL SOCIETY'S PRIZE MEDAL.

My guidman got a medal hame,
An' hauds his prize wi' muckle glee;
Its legend set my thochts aflame:
'Tis "Aye be stickin' in a tree."

Stick in a tree, nae matter where,
On bare hill-side or tufted lea;
For when you walk the earth nae mair
Its boughs may green and verdant be.

Time was when a' oor mountain stood
Tree-clad from base to summit hie,
But aye men cut the growin' wood,
Nor thocht o' "stickin' in a tree."

An' noo the brown hill-tops look down
On miles o' woodless countrie,
Because some thochtless lording's frown
Forbids them "stickin' in a tree."

Scotland, when shall thy glory cease,
An' a' thine ancient prestige flee?
When men forget in time of peace
To "Aye be stickin' in a tree."

Oh, dear old rugged mountain land,
An' nursing-place of Forestry,
Lang may thy sons, a stalwart band,
Tak pride in "stickin' in a tree."

—*Journal of Forestry.* K. KAY.

QUICK RETURNS IN APPLE CULTURE.

The old fallacy, that in planting apple or other fruit trees we benefit posterity more than ourselves, is happily now exploded, seeing that really good crops can be had off trees the second year after planting, if grown on the Paradise stock. Tiny trees, one, two, and three years from the graft, now bear crops of marvellously fine fruit, such as makes even old Kentish fruit-growers open their eyes with wonder. In the fruit-tree nurseries at Allington, near Maidstone, I last year saw trees not so large as ordinary gooseberry bushes covered with fruit, the size and colour of which were extraordinary. Apples being at the time a drug in the market, the fruit was lying thickly in all directions; and I was assured that there had been a deal of labour expended in divesting the young trees of their superabundant crops, for fruit was not the object sought for, but trees and bushes. Yet where a few rows of trees were standing with three or four years' growth, I question if it would have been possible to have grown a larger crop per acre by any other means, for the bushes quite touched each other, no room being left to get between the rows without knocking off the fruit.

Anyone contemplating apple culture in gardens should make it a special point to go into some nursery and see for themselves how these little apple bushes on the Paradise stock behave; this is essentially a garden apple stock. Apples on this stock may be grown on low trellises running north and south, feet as rows of peas are now grown between dwarfer vegetables, or as edgings to walks, or in any other way the cultivator may fancy. The simplest and possibly the best mode is dwarf bushes about six feet apart, like gooseberries and currants. Procure the bushes in October or November, plant them at once, and mulch the roots; shorten the shoots in winter, and pinch them in July. The trees will need but little other attention, and will certainly reward one with abundance of fruit.

The orchard is quite a distinct affair. In this case large trees on the free stock, capable of bearing from twelve to twenty bushels of apples, is the only way in which the fruit can be produced cheaply enough to pay the grower. There is no difficulty whatever in growing apples enough in England to supply all our wants, and of a quality superior to those imported; but the producer and consumer should be brought nearer together. In the meantime all who have a little garden of their own may soon be independent of both markets and importations. Buy a few little bushes of varieties that become fit for use in succession, for both culinary and dessert purposes; and if the produce is not found juicier and better than such as will stand a trans-Atlantic voyage without bruising, all I can say that is my experience has misled me.—J. G. LINTON.—*Field.*

METHOD FOR THE ESTIMATION OF TOTAL ALKALOIDS IN BARK.*

BY DR. J. DE VRIJ.

In the *Archiv der Pharmacie* for August, 1881, two methods for the estimation of the total alkaloids in bark were proposed by Prollius, one of which the author has tested and now recommends as yielding, with a slight modification, excellent results.

The principle of the method referred to consists in using for the extraction of the alkaloids a mixture of 88 parts (by weight) of ether, 8 of alcohol (92 to 95 per cent), and 4 of liquid ammonia. Prollius directs 10 grams of this liquid to be taken for every gram of bark, but the author recommends the proportion of menstruum to be doubled.

The following is the method as modified by the author:—10 grams of finely powdered bark are introduced into a well closed bottle and, after being carefully tared, 200 grams of the ethereal liquid are added. The whole is now shaken at intervals during an hour, this length of time having been ascertained by comparative experiments to be sufficient. The bottle is then again weighed, and if evaporation have taken place the necessary quantity of ether mixture is added.

As much as possible of the clear liquid is now poured off into a flask and the bottle again weighed; the difference in weight gives the amount of solution taken. The ether is then recovered by distillation and the residual liquid, containing alkaloid and waxy matter, is transferred to a tared porcelain dish and glass rod, the flask being washed with a little spirit. The evaporation is now continued on the water bath until the weight is constant. This gives the amount of crude alkaloid. For instance 10 grams of succirubra bark were digested with 200 grams of ethereal liquid. 159·8 grams of the clear solution gave a residue of 0·78 gram, or 9·76 per cent of crude alkaloid.

To estimate the pure alkaloids the crude residue is dissolved in dilute hydrochloric acid, filtered, washed as long as the washings precipitate with solution of soda, and the whole made alkaline and shaken with chloroform. After standing twelve hours the clear chloroformic solution is run into a flask and evaporated by distillation. The residue is transferred with a little spirit to a tared dish and stirred and heated on the water-bath till the weight is constant. Particular attention should be paid to the latter point. In the instance referred to 0·648 gram of alkaloid was obtained, equivalent to 8·11 per cent or about 1½ per cent less than the amount of crude alkaloid. The author is of opinion that by estimating the crude alkaloid and deducting 1½ per cent a result will be arrived at with loss of but little time, which, for the practical purposes of the pharmacist, will be sufficiently near the truth. Of course the same method is applicable for the examination of the ext. cinch. liq. (de Vrij).

* Abstract of a paper in the *Nieuw Tijdschrift voor de Pharmacie in Nederland*, January, 1882.

From a sample of cinchona bark 10·01 per cent of pure alkaloid was obtained, whilst a former estimation by the lime and spirit method had yielded 10·02 per cent. The close agreement of these two determinations confirms the reliability of this method, which the author confidently recommends.—*Pharmaceutical Journal.*

SEED POTATOES.

A correspondent of an American farm paper, the *Country Gentleman*, published at Albany, New York, makes mention of a fact which has no little significance for English potato growers. Writing from Kentucky, he dwells upon the difficulties with which potato culture is now surrounded there. Not only have the Americans—to use his own phrase—"to fight the bugs," but their favourite variety, the Early Rose, has shown great signs of wearing out. Seed appears to have been got, for a time with advantage, from New York State into Kentucky. But more recently another plan had been adopted, and, the correspondent of the Albany paper states, with very marked success. This was to plant Early Roses very late, and to take up the imperfectly ripened tubers in the autumn, and use these for the seed the following spring crop. It was found that seed so grown produced an earlier crop, and one more free from under-sized potatoes, than did seed of a crop grown under more natural conditions. As the letter (in the American paper) reads, it would appear that as a rule seed potatoes, early ripened, exhaust themselves in America by shooting before the planting season of the next year arrives, and that they yield a feeble plant. Now the potato beetle "seems to prefer a weakly vine to the strong thrifty ones." In contrast it would appear that the immature seed, taken up in the late autumn months, does not send out any sprout until it is planted for a crop, when, "however, many eyes it may have, each potato only pushes one, which often comes out of the ground half an inch in diameter, and branches out into a large, thrifty, healthy vine—the very kind needed to withstand the ravages of the bugs." And the letter goes on to state that even this method of growing special seed had been improved on. A gardener found that it paid better to plant potatoes of the first crop to produce a second—*i.e.*, two crops are grown in one year, the first providing the seed for the second. "About the middle of July the potatoes of the first crop are dug, cut, and planted again. It generally takes them about six weeks to come up, and by the middle of October they are about the size of a hen's egg. If no larger than a pigeon's egg, it makes no difference, as they do as well as if larger."

No doubt other English growers besides myself have ascertained that there really is some truth in the principle which is here laid down, *i.e.*, that immature seed vegetates more strongly and earlier than does seed which has fully ripened. In 1878 I discovered that some potatoes of a late variety, which had been taken up in July in order to make room for the bricklayers, and allowed to be about till they were quite shrivelled, produced the only piece of winter potato in 1879 which escaped the disease. Right and left of the rows from this seed the crop was wholly spoiled; but the rows actually grown from this seed gave a full yield of fine tubers. In 1880 a like result was obtained, *i.e.*, the crop from very immature seed was the best of the season. Nor does 1881 tell a different tale. I took up some potatoes for seed early in July 1881, and placed them away in trays, and set the trays out of sight upon a high shelf. As the variety was a favourite one, and the quantity put away was small, the surplus potatoes from another portion of the same crop (which had been allowed to ripen in order that they might be eaten from the ground) were also put away in trays in October, and these trays placed side by side with the former lot upon the same shelf.

Reading the account in the American paper, I have just gone and examined the two lots. The former (the immature seed) have shrivelled very much, and have sprouts two inches long, with abundance of rhizomes emitted. The latter are firm, with the eyes just pushing, *i.e.*, about a sixth of an inch long. There can be no question but that the immature seed, if it have not spent itself too far (for, in consequence of the unusually bright sunny winter, this seems to be possible), is far more likely to produce an earlier crop than are the later tubers. It has occurred to me that one reason why the earlier tubers escaped disease in 1879 was that they were taken from the ground in 1878, before the Perinospora infestans had developed itself. Now the seeds of that pest do not attach themselves to the roots as a general rule, and are less likely, if in the air, to fasten on the withered skins of the tubers. I believe that the Perinospora infestans work upon the tubers from within, *i.e.*, that it descends in the sap of the infected vine down into the veins of previously healthy tubers. If so, the immature seed (removed from connection with the vine before the vine gets infected) is doubly valuable—*i.e.*, it has a tendency to early growth (which is in itself a safeguard); and it is also free within from any of those forms in which the Perinospora is supposed to pass through the winter. At all events, there certainly is some truth in the opinion that immature seed taken up out of season does produce more vigorous growth in the following spring, and a healthier growth too, than do tubers which are part of any ripened crop grown to its full development in order to secure excellence for table purposes—G.—*Field.*

HEDGES.

Next to plantations nothing so much beautifies and adorns the landscape and the country in general as hedges, and the more that agricultural improvements are advanced the more will hedges be appreciated both for beauty and utility. Any one who for the first time beholds the garden-like field formation and distribution of thorn hedges in Roxburghshire, the Lothians, Ross-shire, and some other districts of Scotland, is alike pleased and surprised with their beauty and utility. The first consideration, after determining its purpose, in planting a hedge is what description of plants to plant so as to suit the soil, and effect the purposes of protection and afford shelter to the kind of stock upon the farm. Unless the soil is of sufficient quality to grow a good strong plant, and maintain it in health and vigorous growth in future, it is unadvisable to plant hedges upon it.

After many trials, long practice, and frequent failures, the following among other successful results have been achieved:—In planting common whitethorn hedges the first thing to do is to trench, lime, and otherwise thoroughly prepare the ground, which should either be of a clayey or strong loamy nature. The plant bed should be about 4 feet wide by at least 2 feet deep, and the ground both underneath and on all sides well broken to a good depth, and thoroughly drained. It is advisable to have the preparation of the ground done in summer or autumn, and the planting done as early the succeeding season as possible. The plants preferred are strong seedlings (two or three years old), and should be put in without any cutting except in extreme cases where the roots are extra long and bare, in which case they should be slightly shortened with the knife. I plant nine or ten plants to the yard, and keep the hedge clean by hoeing and raking for several years thereafter, and never cut

over the plants till they have made two years' growth, when, with a sharp hedge-bill, or pruning-knife, they are cut over to within three inches of the ground.

At the end of the second two years' growth they are again cut over at 18 inches from the ground, and again at two years afterwards at 3 feet from the ground; thus, at six years from the time of planting, there is a close and good hedge 3 feet high, as as they seldom require to be more than 4 to 5 feet in height altogether: this height is attained at the end of seven years, after which the hedges may be pruned either once or twice a year as circumstances suggest. One rule ought to be, never to prune the hedges at midsummer till they have attained their full desired height. No young hedges—that is, such as have not attained their full height—should be pruned in the summer season, nor till the young wood is perfectly ripe and matured, otherwise pruning stultifies and throws the hedge into a state of distorted and gnarled growth from which it never afterwards quite recovers.

I prefer planting hedges comparatively thick, and when they require it thin them out with a pruning knife, which is a commendable practice, as thereby the remaining plants derive more room and consequently grow stronger.

The prunus myrobalana appears also to be (for it has not been long much in use) a very good hedge plant, but requires mixing either with common Thorn, Sweet Brier, or other less rapid growing species to thicken and give compactness to the hedge. This kind of hedge is planted and treated in every way the same as Thorn hedges, but the plant requires a still better soil to grow in, nor is it certain if it will grow to such old age as the Thorn even under the most favoured circumstances.

Whins or Gorse also make good hedges, which succeed well on turf dykes, but in consequence of their liability to die periodically from the effects of frost and their attraction for rabbits they are less planted now than formerly. The Whin hedge is sown (rarely planted), and the common method is to make a scratch in the ground, as if for sowing Turnips, and from a bottle with a goose-quill fitted into the mouth the seed is sown and covered with a small rake or hoe. The plants come up the same season as sown, and require little further treatment beyond keeping the grass from chocking them the first and second season, and annually pruning the hedge after shedding its flowers.

It is an excellent plan to extend one or two runs of wire in both Whin and other hedges as near the top as possible, to constitute a back-bone to them, which is of the greatest importance wherever cattle are to fence against, for there are few hedges in which there are not some weak parts, and the strength of a hedge, as of a chain, is determined by its weakest part.

Mixing hedges, as Thorn and Beech, though common, is not commendable, because if the soil is adapted to Beech it outgrows and kills the Thorn, and if suitable to Thorn it grows much better without the Beech. In winter, too, a hedge composed of Beech and Thorn always presents a gappy appearance at a distance, for in spite of all efforts the one or other die out. Evergreen hedges for their own sake should be annually pruned in May, when all the old and withered foliage is pruned off, and the young shoots allowed freedom and time for completing their growth before the end of the season. There are, however, opposing considerations which have to be taken into account, such as the flowering of Whins, Rhododendrons, &c., and it is not till these and others have shed their blossoms that pruning is admissible. The beauty and neatness also which a newly-pruned hedge presents at midsummer has of itself such attraction that it may be some time before Nature's laws are, in regard to pruning, fully obeyed.—C. Y. MICHIE, Cullen House, Cullen.—*Gardeners' Chronicle.*

THE INDIA-RUBBER TREE.

The way in which this remarkable tree, Ficus elastica, became known to botanists and horticulturists was very singular, as related by Roxburgh in his *Flora Indica* iii., p. 543. Towards the close of 1810 a Mr. Matthew Richard Smith, of Silhet, sent Roxburgh a vessel, there called a "turong," filled with honey in the very state in which it had been brought from the Pundua or Juntipoor mountains north of Silhet. The vessel was a common, or, rather, coarse basket, in the shape of a four-cornered, wide-mouthed bottle, made of split rattans, several species of which grow in abundance in the above named mountains, and contained about two gallons. Mr. Smith observed that the inside of the vessel was smeared over with the juice of a tree which grows on the mountains. Roxburgh was therefore more anxious to examine the nature of this lining than the quality of the honey. The turong was accordingly emptied and washed out, and Roxburgh then found that it was very perfectly lined with a thin coat of caoutchouc. Young trees were speedily procured through Mr. Smith, and cultivated in the Botanic Garden at Calcutta, where they throve with the greatest luxuriance. The name only was first published in Roxburgh's *Hortus Bengalensis* (1814), p. 65. When we say name only, we mean without description, although Roxburgh indicated that it was a large tree, and gave the season of flowering and fruiting. Recently Dr. Brandis (*Forest Flora*, p. 418, in a footnote) has stated that Blume must stand as the authority for Ficus elastica, "because Roxburgh did not include it in his *Hortus Bengalensis*, and his *Flora* did not appear till 1832, whereas Blume published it in his *Bijdragen tot de Flora van Nederlandsch Indië* (1825), p. 446." But this objection fails, inasmuch as the name is included in the *Hortus Bengalensis* in the place quoted. Blume received the plant from the Calcutta garden, and published the name as his own. We sometimes find Linnæus cited as the authority for the name, but, as we have shown, it could not have been known to him.

In 1815, five years after its discovery, as we learn from Sweet's *Hortus Britannicus*, 2d ed., p. 461, it was in cultivation in this country. Its hardy nature enabling it to bear smoke, dust, gas, wet and drought, better than most other plants, it soon became a common and favourite ornament in sitting-rooms, and other parts of dwelling-houses, as well in this country as on the Continent. Although it will bear a great deal of rough treatment it repays a little care by producing leaves as much as two feet in length; but for indoor (dwelling-house) decoration it should be kept in small pots, in moderately rich soil, or it will soon outgrow its space. Indeed, it is remarkable how long this tree, which attains gigantic dimensions in a wild state, may be kept healthy and ornamental in a mere handful of earth. With regard to the size of this tree in its native country, we find some interesting particulars in William Griffith's "Report on the Caoutchouc Tree of Assam," in the *Journal of the Asiatic Society of Bengal*, vii, part 1, p. 132. In the district where it grows it overtops the other vegetation, not only growing tall, but forming colossal trunks. The dimensions of one tree measured by Griffith were:—Circumference of main trunk, 74 feet; ditto of main trunk and supports, 120 feet; estimated height, 100 feet. The nature of the trunk is very extraordinary, and is thus described by Griffith:—"It differs in the first place from the ordinary trunk by its sculptural appearance, and it is from this that its extremely picturesque appearance arises. The appearance arises entirely from the tendency of these trees to throw out roots, both from the main trunk as well as from the branches, and from the extreme tendency these have to cohere with the

trunk or with each other. If the roots are thrown out from or very near the main trunk, they ordinarily run down its surface, and cohere with it firmly, and hence the sculptured appearance. If, as happens in some, they are thrown from the branches at such a distance from the trunk that they do not come in contact with it, they pass down to the earth and form what I call supports. These supports never appear to produce leaf-bearing branches, so long, at least, as they remain attached to the tree. They are generally perfectly straight at first, becoming conical only by divisions at the apex when near the earth, and by the mutual adhesion of these divisions. Very generally it would appear this species, as well as some others, vegetates in other trees; its first processes of growth being probably similar to those of other dicotyledonous trees. The roots, however, in obeying the laws regulating their descent, soon come into contact, and wherever they do so a mutual and firm adhesion is the result. A network is soon formed round the tree; the size of its reticulations soon diminishes with the increase in the number of roots; and at last a nearly solid and excessively firm cylinder is formed, which encloses, as it were, in a case, the tree which originally protected the young seedling. To such an extent is this carried that the death of the tree is sure to occur sooner or later. In such a case as this the fig tree has, it may be said, no trunk at all comparable to ordinary trunks, which result from growths in an ascending direction. In these they originate from the aggregation and cohesion of roots, or from growth in a descending direction." From Griffith's observation it appears that this tree rarely fruits in a wild state, and still more rarely does it fruit under cultivation in this country. An instance occurred in the garden of Mr. Boyce, of Clapham, in 1874, and the fruit was figured in this journal, n. s., ii., p. 359.—*Gardeners' Chronicle.*

THE IMPROVEMENT OF SOILS.

A pamphlet, "How to Profitably Improve our Soils," by Dr. J. E. Taylor, F.G.S. (published by E. Packard & Co., Ipswich, price twopence), is probably issued with the object of giving correct information as to the nature and use of chemical manures. We can only say that, if so, it is a very legitimate object, and, judging by the ignorant remarks frequently made, Dr. Taylor's clear exposition of the nature of soil; requirements of plants, and action of manures, may be read with advantage by those who denounce artificial manures as merely stimulants, and believe that their action is quite different from that of farmyard manure. It is high time that this truth is realised, viz., "that farmyard manure depends for its efficacy upon containing certain ingredients in certain proportions, viz., nitrogen, phosphate of lime, potash, lime, and possibly magnesia; and that these ingredients can be presented more directly in the form of a compound manure; and so, according to Professor Ville's experiments, the latter, if no richer than the home-made manure, produces better effects, because more immediately available." Farmyard manure, however rich it may be in the constituents which crops required as food, cannot yield it to them as fast as chemical manures can; for the simple reason that the former decomposes slowly, and the crops cannot get it faster than the rotting manure yields it to them. Indeed, no less than ninety five per cent of farmyard manure is composed of carbo-hydrates, of which there is already perhaps too much in the soil. It is for the same reason that the effects of farmyard manure last longer in the soil than artificials. What, however, is wanted now is a quick return, and the use of artificial manure, with or without foldyard manure, secures this.

If Professor Ville is correct as to the almost useless nature of 95 per cent of home made manure, surely it is very unwise to make hard-and-fast rules as to the consumption of straw, when the same could be sold at remunerative rates, and its manuring value replaced by suitable applications. If, again, we are able to restore to the soil those particular materials abstracted by certain crops, we are no longer bound down to a rigid adherence to a rotation. The system of alternating crops was a wise and necessary one, when the farm depended so much upon its own resources for manure, and it will still be found desirable as a general rule. Different classes of plants exhaust the soil of certain elements in very different proportions. This fact, and the materials essential for growth, were proved by Professor Ville in a series of very beautiful experiments. The matrix used was sand, first calcined, so as to destroy all manuring matter. "Wheat sown in this sand, with the addition of a little water to moisten it, only just sprouted; even the straw did not grow so large as a knitting-needle; and when nine out of the ten elements, which are more or less necessary to plants, were added to the calcined sand (nitrogen being excluded), the growth was very little better. When nitrogen was added, but the nine elements left out, the result was nearly the same; but when both nitrogen and the mineral matters were added, the results were almost magical."

Professor Ville found that the conditions most favourable to fertility consisted in the union of four substances—nitrogenous matter, calcic phosphate potash, and lime, to which mixture he has given the name of normal manure. "His experiments with these materials were most interesting. Without any manure at all, the soil produced 12 bushels of wheat; with chemical manure, but without nitrogen, the yield was 18 bushels. Treated with nitrogenous matter, without minerals, the yield was 22 bushels; but treated with the 'normal manure,' the yield jumped up to 50½ bushels per acre."

As an illustration of the economy of rotations, it is pointed out that clovers and leguminous crops generally flourish in soils containing little or no nitrogenous matter; and not only so, but are able in some mysterious way to obtain nitrogen from the atmosphere, and to store up a portion in the soil. The fact is well-known to chemists. It has been proved that a soil from which two crops of clover have been cut, thereby taking away a large amount of nitrogen, is richer in nitrogen than it was before the clover was sown. The absolute necessity for phosphorous in the soil, especially for seeds and tubers, is pointed out. And not only is phosphorous an element found in all seeds, but the pollen of all kinds of plants is rich in phosphorous, and without its available presence in the soil at the time of flowering, imperfect fertilisation must result. The importance of soluble phosphates in the soil is thus established. Plants apparently have an extraordinary power of obtaining this manure, even when present in an insoluble state. Professor Jacks proved this by planting seeds in moist sand resting on polished slabs of *phosphorite*. They germinated there, reached down to the polished phosphate beneath, and thus dissolved out such quantities as they required, leaving on the polished slab an etched outline as a self-written record of how important this mineral was to their growth. We all know the effect of applying finely-ground bones, and even coprolites, to the soil. Here is an explanation of the efficacy of insoluble phosphate.

In the present condition of English farming it is quite impossible to do without large supplies of chemical manures. It is, therefore, well that farmers should have sound knowledge afforded them as to what they should use and what they should avoid.—*Field.*

THE HOLLY.

The holly is a general favourite, and it is found more or less in all ornamental grounds and policies. When planted out singly it has a very striking effect; it also forms a close ornamental hedge, and is used very extensively as underwood. There is a great variety of hollies—golden, silver, smooth, prickley, &c. There is one variety (*Ilex Paraguayensis*), a native of South America, the leaves of which are dried and roasted, and used as tea by the natives: so great is the demand for it that nearly eight million pounds are consumed annually. The common holly (*Ilex aquifolium*) is raised from seed, which ripens during the winter months. Some trees ripen earlier than others, according to situation and exposure. Great patience is needed in the management of the holly berries; they must lie a year amongst sand, in which they must be well bedded, to prevent them heating: care must also be taken to protect them from the ravages of mice. After lying a year in the heap, they should be sown in beds about three-and-a-half feet broad, amongst free, light soil if possible; when the seed is sown it should be clapped down level with the back of the spade, and a thin covering of fine pulverized soil spread on the top.

It sometimes happens that but few plants come up the first year; when this is the case the bed must just be kept clean until the following spring, when a second and fuller braird will appear. It may happen, however, that the seed may be inferior and never germinate at all; but it is a safe rule not to be in a hurry to dig over the seed-bed. The holly thrives best on a light, dry soil, for there is no plant that succumbs more quickly to the effects of wet than the holly. There is a fine holly hedge on the Dalkeith Park Estate, and on several occasions part of it have turned brown and sickly. On examining the roots I invariably find that they have come in contact with stagnant water, or stiff, impenetrable soil; when this is remedied the plants in a year or two get strong and healthy. There are also thousands of hollies growing all over the estate as underwood, and the best plants are found on a light, loamy soil, resting on a bed of gravel. The plants on the outside of the plantations with an open exposure form an impenetrable thicket, as many of the under branches take root, and send out a mass of vigorous growth; this forms excellent cover for all kinds of game, pheasants especially, as they roost amongst the branches at night. In order to make good cover, therefore, hollies must have room; if they are crowded together you only produce bare poles.

Where the soil is suitable, 30 feet apart will be found to be a good average distance for planting holly as underwood. Sometimes hollies get drawn up when growing immediately under forest trees with dense foliage; when this occurs the tops should be cut off, which has the effect of thickening the undergrowth.

I do not wonder that the holly has become a universal favourite; its shining foliage studded with red berries gives to the woods quite a gay appearance, even in the dead of winter. Throughout the festive season also the holly figures largely in all kinds of decorations, the other evergreens appearing very tame without it. But, although it is one of the best evergreens, I am sorry to say it is also one of the most attractive to vermin, for unless it is protected it is literally at the mercy of hares and rabbits. Unlike other trees, it does not protect itself by forming rough or corrugated bark at its base; hence a plant forty years old is just as liable to be destroyed as one newly out of the nursery. It is quite a common thing to find during a heavy snow-storm trees a foot in diameter peeled round and round beyond recovery. I do not know of anything more disheartening than to have a lot of hollies, which have cost no little trouble in the rearing, killed off in this way. There is no use in blinking the fact that, unless hares and rabbits are kept down within a certain limit, it is needless to attempt to grow hollies. I include hares, for they are just as bad as rabbits. I do not suppose that these animals will ever be exterminated, and so long as even a few of them are roamingabout, so long will hollies be exposed to damage from their attacks.

I read with great interest an article by Mr. McCorquodale, in the *Journal* for August, on the subject of how to protect trees from rabbits. I would feel obliged if he would let us know if he has tried the experiment of rubbing the tar on the trees in its cold state, by means of a rag, because up to this time I have found it necessary to give it a gentle heat, so as to spread it equally over the surface, and also to make the coating as thin as possible; and instead of a rag, we use a brush. I confess that I do not see any analogy whatever between a tree and the human body as illustrating the point in hand. If it is true that our skins are more tender and porous than the bark of trees, and our food and assimilating organs the opposite of theirs, then those are the very reasons why they should be treated differently, and ought not to be compared with each other.

We have used coal tar for many years to protect our hollies. If the stems are about three inches in diameter, it does not seem to do them any injury, but anything under that has to be treated very cautiously. There is no doubt at all that tar has an injurious effect on the tender bark of young hollies, as I have seen them frequently die from its effects; in such cases it was a choice of the lesser of two evils.

During the months of July and August I have been trying a new experiment in the way of protecting hollies. While engaged in thinning oaks, we had occasion to cut down about fifty Spanish chestnuts. We got those trees carefully peeled, and cut the bark into 18 in. lengths. After arranging the different sizes, two men were told off to put a length of bark round each holly stem; as a rule very little fitting was needed, the only fastening required being a piece of rope yarn to keep the bark together. We have operated upon 200 hollies in this way, all good specimens, but which had all been nibbled at more or less during last winter. In going through them lately I find that the bark has shrunk tightly round the holly stems, and the rope yarn hanging quite loose; I intend to let it remain, however, as the bark may slacken if wet weather sets in.

Now, some of these hollies have their branches nearly touching the ground, and it is next to impossible to detect the chestnut bark, as its colour is almost identical to the holly, and, where it is seen, it is certainly preferable to the black coating of tar. Where the trees are large, we found that the appearance of the bark was improved by vandyking its upper edge. As this experiment is new, I cannot say much about it yet, but these guards have this recommendation, that they are cheap, are easily applied, and at the least will stand for six or seven years. ROBERT BAXTER.
—*Journal of Forestry.*

THE MAHWA TREE.

This is one of the Indian food-trees. The name is spelled in a variety of ways, Mhowa, Malwah, and as above Mahwa, and is applied not only to the *Bassia latifolia*, but to *B. butyracea* and *B. longifolia**, which also bear edible fruits. The singularity of the genus consists in the fact, that not only is the fruit eatable, but the fleshy deciduous corollas are also largely employed by the natives of India for the same purpose, constituting in point of fact a staple, and indeed sometimes the only article of diet available for the very poorest classes during some months of the year. The tree is not unlike our oak in form, size, and the colouring of the foliage; it grows from thirty to forty feet high; flowers in the months of March and April; is found in nearly every part of Central India, and is

* Iruppei of the Sinhalese and Illupei of the Tamils in Ceylon.—ED.

cultivated in other districts, but not so largely as it might be, considering its valuable properties.

The flowers ripen towards the end of February or beginning of March, the corollas becoming fleshy and tinged with the juices they secrete. They then gradually loosen from the calyx, and falling to the ground, are carefully gathered by the natives—women and children being chiefly employed in this business. They start in the early morning from their villages, carrying baskets and a supply of water for the day's use, to where the Mahwa trees grow.

Just before the blossoms are ready to fall, the grass is burnt away in a circle from beneath the trees, in order that none of the precious blossoms may be hidden by it, and so lost. The gleaners of the Mahwa crop remain in the neighbourhood of the trees all day, collecting and sleeping by turns, and return home at night laden with spoil. When the gleaners have come from a long distance, they often make a temporary encampment of huts, formed of branches of trees, and live on the ground until they have collected all the flowers. They never strip the trees entirely of blossoms; in good seasons, each tree will produce from two to three hundred pounds of flowers; and a good many are allowed to remain to seed themselves.

The natives clear a piece of ground in front of their huts, and on this spread out the flowers to dry in the sun. When quite dry, they are reddish brown in colour, and have shrunk to about three-fourths of their ordinary size, and lose at least half their weight.

The tree is a hardy one, and even in poor ground flourishes well. It could therefore be cultivated on land which would not yield ordinary crops. The trees are rented, and the rent varies with various circumstances, such as their abundance in the district, and the quality of the previous rice harvest. Mr. V. Ball, of the Geological Survey, says that in the Murpa district the prices paid for permission to collect vary from twopence to four shillings; and from one hundred and twenty to four hundred and eighty pounds per rupee—two shillings—is the price paid for the saved crop. Very often the exchange is made in kind, in salt or rice; the merchants then give a small quantity of salt, and six or eight pounds of rice for a *maund*—eighty pounds—of Mahwa. During the time of the famine in Manbhoom, the average price of Mahwa was twenty-four pounds for one rupee.

Two *maunds* of Mahwa are said to be enough for a month's food for a family of five. It is not generally eaten alone, however, but mixed with different seeds, those of the *Shorea robusta*, the *sál* tree; and very often rice is added also. When dried, Mahwa flowers rather resemble inferior figs. When fresh, they have a sweet taste, but a by no means agreeable odour. The fruit succeeds the blossoms. It is about the size of a very small apple; and the kernels contain oil, which is of an inferior colour and rancid taste, but is very generally used by the poorer natives for lighting purposes, as well as for cooking; and it is also applied externally as a remedy for wounds, sores, and cutaneous diseases generally.

The freshly-dried flowers yield, on distillation, a very intoxicating spirit, called by the natives *daru*. It is usually diluted with from five to ten times its bulk of water, and is then offered for sale at about a penny per quart. Its smell, which is most offensive, cannot, even by the most careful distillation, be wholly got rid of. The natives, however, do not seem to mind it in the least; and even British soldiers acquire a taste for the liquor in time, though they generally hold their noses while drinking it. One hundredweight of flowers is said to yield from four to six gallons of proof-spirit. The very carefully distilled and rectified spirit is put into oak-casks, becomes of a yellowish colour with keeping, and is said to be little inferior to the best Irish whisky.

The oil is manufactured from the seeds by bruising, rubbing, and subjecting them to heavy pressure. It is a coarse sort of oil; but in the manufacture of soap is largely used in the country, and also for candles. For that purpose, it would be worth in England from twenty-five to thirty-five pounds per ton. It has been tried by candle-manufacturers, and pronounced very suitable, and a valuable oil for such purposes.

Useful as the Mahwa tree is, and valued as it is by the natives, still, they do not protect or foster its growth as much as it might be thought they would, considering that the flowers and fruit are alike useful for food, drink, and domestic purposes. The cultivation of the tree is not so great as it well might be. This culture might, with very considerable advantage to the country be fostered by the government, as the trees would yield a revenue, by the duty on the spirit distilled from them, as well as afford food for the poorer native population at certain seasons of the year. No outlay is necessary, as they are very easily grown from seed, the trees propagating themselves in those parts of India in which the tree is indigenous, the seed being generally self-sown. In the Concans, the Circar Mountains, Bengal, Rajputana, Guzerat, &c., the Mahwa tree grows in considerable numbers, and it might easily be spread from thence over all India. The natives are sufficiently alive to the value of the trees to protect them in those places in which they exist, but do little or nothing towards increasing their numbers; and the increase of cultivated land prevents the seedlings springing up, as they would otherwise do in many places. With a view to securing the preservation of Mahwa trees in village areas, it is not now allowed to cut them down, even when they have ceased blooming, without permission. This is a step in the right direction; and if attention is turned towards the cultivation of seedlings throughout India, one of the best food-trees of the empire will be preserved from extinction.—*Chambers's Journal.*

INDIA-RUBBER AND GUTTA-PERCHA IN THE FAR EAST.

Dr. L. Pierre, Director of the Botanical Garden at Saigon, in French Cochin China (about the same latitude as Tenasserim), has recently made some interesting observations on the rubber and gutta yielding trees of Cochin China and Cambodia, in No. 2 of "Cochin Chine Française: Excursions et Reconnaissances," an official work published at Saigon.

Siphonia elastica, introduced *vid* Java, is apparently certain of establishment, though not yet seriously cultivated; *Ficus elastica* has also been introduced. It is, however, to the indigenous plants that Dr. Pierre's attention has chiefly been directed. He speaks of three native species of *Euphorbia*, not worked by the inhabitants of the country, though easily cultivable, and growing on the driest and most unlikely soil, which afford a medium or inferior product, and are considered to be worth the attention of the Government; and he also mentions an allied plant of very wide distribution and rapid growth, *Excœcaria oppositifolia*, which furnishes almost abundant milk. But the most remarkable plant in Cochin China, from the caoutchouc-producing point of view, is one of the *Apocyneæ*, *Parameria* (or *Ecdysanthera*) *glandulifera*, on which positive and entirely conclusive experiments have been made. This plant is a liana or creeper, which grows to the tops of even the highest trees, and is found abundantly in all the forests of Cochin China, chiefly at Cam-xay Phuquoc, Poulo-Condore, and in the environs of Tayninh, Baria, and Bienhoa, being excessively common near Xong-lua (we retain the original spelling): nevertheless, the natives do not know how to extract the rubber from it.

The diameter of this creeper when full grown (say in ten years) is nearly two inches. The juice that flows from it presents exactly the appearance of milk,

and can be used like it, having a slightly nutty flavour. In its liquid state it is often employed as a medicine by the Annamites and Cambodians. The bark, after being dried (usually by fumigation) is sold at the rate of from 20 to 25 frs. the picul (133 lb.) and sent to China, where its medicinal properties are much appreciated. It is to be had in all the markets of Cochin China under the name of "dau" or "dô tam" in the Annamite, and of "wâbrr angkôt" or "whole angkôt" in the Khmer language.

The method employed for the procuring caoutchouc is of the very simplest nature; it is only necessary to pour the juice drawn from the creeper (either by incisions or cutting it up into small lengths, if a larger quantity is wanted at once) into a basin of water of the temperature of 40° or 50° (presumably centigrade, equivalent to 104° or 122° Fahr.), when, on being stirred with a rod, the milky mass is instantly converted into an excessively pure rubber of unrivalled quality.

This plant is propagated by cuttings with astonishing rapidity. Introduced into the botanical garden at Saigon in 1874, it had, by climbing up trees, reached in 1877 a height of from 26 feet to 33 feet. It could be planted so as to economise space without harm under any forest tree not less than ten years old, when the now devastated forests of Cochin China are regularly taken in hand; or it could be trained at the foot of fruit trees grown as hedges. In this way the almost entire want of any necessity for cultivation, and the double utilisation of land generally considered worthless, would combine to render the plant the source of a very paying revenue.

As to the now possible working of the creeper as it grows in a natural state in the forest, the only way would be to apply to the Chinese and the native traders (especially the Cambodians), who for an adequate offer would collect the juice. It is solely a want of care and the present state of infancy of French commerce which have caused the product of so valuable a plant to be hitherto neglected, says Dr. Pierre, who mentions among other *Apocyneæ* in the Botanical Garden a species of *Willughbeia*, very vigorous and a rapid spreader, and yielding a very abundant juice, though its rubber is possessed of but slight elasticity.

As india-rubber is apparently now increasing in market value, it may be worth the while of our settlers in British Burma and the Straits Settlements to pay careful attention to the rubber-yielding Apocyneous plants growing wild in those countries, which are in about the same latitude as Saigon, and present similar climatic and geographical conditions, being also parts of the Indo-Chinese peninsula. Economic botany has not been neglected in them, it is true; *Ficus elastica* has been introduced into British Burma and thrives as far as mere growth goes, though it is yet too early to judge whether it will retain its quality out of its natural limits. *Chevanesta esculenta*, a caoutchouc-yielding creeper, has also been planted in the Ma-ga-ree Forest (British Burma) and grows vigorously; but it is to the native plants that attention could apparently be profitably turned, and of these, *Ficus laccifera* (in Burmese "Gnyoung"), which grows in the evergreen tropical forests of Pegu and Tenasserim, is stated to yield a very good rubber, equal to that of *Ficus elastica*; and there are many other native species of *Ficus* and *Artocarpus* yielding caoutchouc of different qualities. Another plant, *Isonandra polyantha*, found in the forests of Arakan, yields gutta percha probably not inferior to that of Singapore (according to Spearman's *British Burma Gazetteer*, 1880); but it is evidently to the resinous gums that most attention has been paid by Colonial botanists here.

As regards gutta-percha, Dr. Pierre points out the present state of uncertainty as to the exact trees which furnish the very varied qualities of that commodity coming into the market under the names "Macassars," "Borneos," "Sumatras," "Banjermassins," and "Singapores"—purely commercial designations, which afford no indication of the local origin of the species. "Borneos" are known to be inferior, but the others are subject to great variation; and it is a curious thing that no collectors, Chinese, Malays, Dyaks, or others, can be induced to supply specimens of the trees which furnish the gutta they bring. Hooker's original gutta-tree, brought by Lobbe from Singapore, and described as an *Isonandra*, is now known with certainty to be a *Dichophis;* but it is still not known whether this is the tree that supplied the best commercial gutta, for which the southern part of the Malayan peninsula Borneo, Bantam, and the neighbouring isles, must probably be searched. The only commercial gutta really traced to a tree is that obtained in Larut by Messrs. Brau de St. Paul Lias and De la Croix, through Mr. Low, our Resident at Kuala-Kangsar. The tree from which this came is figured by Dr. Beauvisage under the name of "Gnentta seundek," and is supposed by him to be the *Keratephorus Leerii* of Hasskarl, which is now known to belong to the genus *Payena* a Sapotaceous plant. Dr. Pierre notices another species of this genus *Payena alabasterana*, from the right banks of the Mekong; also a *Bassia* (called "Sang dao"), a *Mimusops* (probably *M. Rauki*), *Chrysophyllum Roxburgii*, two species of *Sideroxylon*, and *Dichopsis krantziana*, as indigenous plants worthy of investigation as yielders of gutta-percha; and he concludes with pointing out the great commercial and economic importance of scientific observations in this direction, in language equally applicable to British Colonies in the Far East.—*Colonies and India.*

THE DATE PALM.

In my garden at Mentone I have planted many Date Palms (Phœnix dactylifera) which flourish all along the Genoese Riviera in the more sheltered regions. They are thriving but developing slowly, except in two instances, which throw a light on the peculiarities of the tree. On one terrace there is a row of Palms planted twelve years ago, all healthy, but small. One of these Palms is an exception to the rule. It is six times larger than the others—2 metres 25 centimetres (7 feet) in circumference, whilst the rest, planted at the same time, are only 75 centimetres 1 foot from the ground. It is quite a tree, and bears yearly fruit that ripens, some of the other Palms being male plants and flowering at the same time. I was long unable to explain why this one Palm should have developed in so rapid and extraordinary a manner as compared with its compeers, but one fine day the mystery was solved. Twelve feet below the terrace on which the Palm grows, on the other side of a thick masonary wall, is a conservatory in which there is a water-tank. On cleaning it out a mass of Palm roots were found at the bottom. They had descended to the bottom of the terrace, passed underneath the masonry wall, and had reached the water. Thus the axiom of the Arabs was literally accomplished—for a Palm to flourish, its roots must be in the water and its head in the flames.

In another part of the garden the same lesson is taught in another manner. One of my neighbours had a right of waterway through my property, and the water passed over a terrace which had been carefully trenched to the rock to a depth of about 5 feet. On this terrace are planted various Palms, and the water passed once a week during the summer in the immediate vicinity of a Livistona australis, a Chamærops australis, a Latania borbonica, and a Cycas revoluta. The recently trenched ground let the water soak in like a sponge, and the four plants named have grown so rapidly that they are now five times the size of all the others in the terrace. My neighbour came to me a year or two ago, and with tears in his eyes accused my plants of drinking up half his water on its weekly passage. In the face of their preposterously rapid growth I

could not deny the impeachment, so I made him a channel outside the property into which the water was diverted. I thus also got rid of his right of presence on his water days. We have to husband the water most carefully, and principally succeed with plants that grow naturally in regions where there are long droughts, such as Mexico, Peru, Chili, the Cape of Good Hope, Australia, &c.

To return to the Date Palms. They do not thrive in regions where they cannot reach water by means of their long strong roots, or where they cannot be watered. The largest Palm forest I have ever seen is at Elche, in the province of Murcia, in Spain. It is many miles in circumference, in a most arid, burnt up spot, but then a small river runs through it; round every tree there is a large saucer or depression, and at intervals throughout the summer the river is turned into these saucers by irrigation canals throughout the summer the river is turned into these saucers by irrigation canals throughout its entire extent. The trees are grown for profit. They produce ripe edible fruit, which are sold in all the markets of this part of Spain as an important article of food. The Dates, however, are not the saccharine Dates we see and eat in the North as a sweetmeat, but a farinaceous dry Date which grinds into flour, and is consumed as such. I was told in Algiers that they cultivate in the desert oases sixty different kinds of Date. I saw very few Date trees in the vicinity of Algiers and along the coast, They are principally cultivated on the southern side of the Mount Atlas, in the numerous oases that are found in the desert within a short distance from the southern basis of the Atlas range.

The existence of these desert oases is easily accounted for. An immense quantity of rain falls in Algeria every winter on the Atlas Mountains, the prevalent winds being north-east or north-west, that is, moist sea winds. Immense masses of water thus fall down the southern slopes of the Atlas, mostly calcareous, and reach the sandy desert at their base. Sinking into the sand they form regular rivers underground, running along the base of the mountains from west to east, or east to west, at a variable depth, according to the amount of earth or of granitic sand that covers the calcareous rocks. Every now and then these subterranean streams come near the surface, forming a marsh or "shott," as it is called, or a fertile oasis if a spring rises to the surface, or even if the water can be tapped by wells. It is in these regions that the Date Palm grows and flourishes by tens of thousands, forming the principal food staple. If the roots reach the water all is well, as with my Palms; if not, and water can be got from deep wells, the Arabs accept the necessary labour and water them.

It is a remarkable fact that most of these marshes and oases springs are strongly impregnated with salt, which seems to suit the tree. The native Arabs get accustomed to these salt waters and thrive on them, but it is a great difficulty with Europeans, and is one of the greatest drawbacks the French troops have to encounter in their campaigns in and occupation of the desert oases. The young Date trees can be planted in soil the water of which is so greatly impregnated with salt as to be undrinkable even by the natives, and that without suffering in the least. They can, it is said, flourish in water containing as much salt as a drachm to a pint. These deep waters are easily reached by artesian wells, which the French are introducing all over the region of the oases at the base of the Mount Atlas range or within moderate proximity.

No other fruit tree thrives, nor do vegetables thrive, in these saline soils, and the vaunted fertility of the oases, except in the case of the Date Palm, is a fable; moreover, in Southern regions, singularly enough, deep shade, such as that given by groves of Palm trees, all but destroys vegetation underneath. Light does not seem to penetrate under shade as in the North, deep shade all but killing ground vegetation: I see this exemplified in my garden. To give partial shade to a patch of artificial grass on a tearace I formed a canopy with a very vigorous Buddleia madagascariensis. I have been obliged to thin it out, for the grass would not grow underneath as it would have done in England. This fact is general, I believe, in the South of France and in all countries where the sun is ardent and the air dry. Light is broken and more diffused in northern regions with a cloudy sky.

Date Palms seem to thrive best in sandy, granitic, schistic soils, but in the proximity of calcareous rocks or disintegrated calcareous soils, at least it has so seemed to me. The sands of the oases of Sahara lie on calcareous rocks, and are watered by rain falling on calcareous mountains. At Bordighera, on the Riviera coast, where these Palms grow in great luxuriance, the soil is principally sand, brought down by the Roya river from granitic mountains, but this sand lies on calcareous rock. In my garden the soil is entirely calcareous, but with plenty of water, as I have said, Palms grow rapidly. The deduction from the above facts is that lime and salt might be advantageously introduced in the artificial cultivation of the Date Palm, and perhaps of other Palms, and that in their period of summer growth they cannot have too much water.

In conclusion, I would add that I have at home at Weybridge a dozen Palms—Phœnix dactylifera, Phœnix palmetto, Chamærops humilis, and Livistona australis—which I imported from Algeria ten years ago, and which have ever since then passed the four summer months in the garden, plunged in the soil. They are planted in the long cylindrical pots I introduced some yers ago (30 inches deep), now known as Palm-pots. They are at present fine large plants, and pass the winter in an unused washhouse through which passess a brick flue from a stove. The temperature has generally been between 40° and 50° Fahr. In summer we water them freely, and they are very ornamental in my garden. I put them out June 1, and take them in October 1. My gardener generally gets the prize for Palms when he exhibits in the local flower shows in competition with regularly stove-grown Palms, and my example proves that the hardy Palms might be much more utilised out-of-doors in summer than they usually are. The position of my Weybridge garden is by no means exceptional. We are very liable to late frosts in spring and to early frosts in winter. But a few degrees of frost does not inconvenience the Date Palm in the least. He has to bear it wherever he grows. According to Canon Tristom (*The Sahara*) hoar frosts are frequently seen at sunrise in the oases of the desert during the winter.—HENRY BENNET, M. D., Mentone, March 7.—*Gardeners' Chronicle.*

THE FUNCTION OF LIME IN GERMINATING SEEDS.—Dr. Liebenberg has recently published, in the organ of the Vienna Academy of Sciences, the results of some researches on the part played by lime in the germination of seeds, from which it appears that there is a great number of plants of which the seeds require lime during germination, or the young plants die off from want of it. On the other hand there are plants that do not need this supply of lime in germination. Dr. Liebenberg further observes that the plants that die off in consequence of an insufficient supply of lime, do not die from the injurious effects of the solutions devoid of lime, but because lime is required in the nutrition of the plant. The author, however, was unable to determine with certainty the purpose of lime in plants, though he proved beyond doubt that the absence of it did not affect the formation of starch.—*Gardeners' Chronicle.*

DEW AND HOAR FROST.

All plants require moisture in order to live and grow, and Nature has provided in the abundant supply of this element one of the principal factors which determine the greater or less vigour of the growth of plants upon the earth.

It is to the copious dews that we have in a great measure to attribute the productiveness of the meadows bordered by rivers.

Water covers about three-fourths of the surface of the globe as ocean, partly in a solid condition, as at the extreme north; partly fluid, as in all warmer regions; it flows through the land in all directions in the form of rivers; it ascends into the air as vapour, and falls again to the earth as rain, snow, or dew. This continuous circulation of "water" produced by "heat," is the especial agent which penetrates the earth, filling it with life and prosperity.

Where water exists the sandy desert changes into a luxuriant oasis; where it is absent, even the greatest richness of soil remains a "waste," and unproductive.

Dew, which forms our particular subject, is the humidity which the air under certain circumstances deposits in the form of minute watery globules on the surfaces of the bodies in contact with it. For instance, on the withdrawal of the sun's rays the atmospheric air becomes colder, consequently the blades of grass, and leaves of plants become chilled from exposure to the influence of the cold, and in their turn cool the damp air which touches them, and cause it to drop its moisture upon their exposed surface. When the condensation of vapours occurs by contact with cold solid bodies it is called "dew;" when, on the contrary, the whole body of air is cooled "mists," "clouds," or "rain" is formed. It is probable that if it were not for the effect of dew the rapid escape of heat from the earth by radiation, the temperature of the soil would become so depressed during the sun's absence, that the extremes of heat and cold in the course of twenty-four hours might be so great as to destroy vegetable life in the summer season: and it is generally after nights of copious depositions of dew that the mornings are the brightest, and the sun's heat the most powerful.

Dew is only formed beneath a calm and cloudless sky, and never in windy weather, for under the influence of wind the moisture of the earth is carried off with extreme rapidity. A north wind also checks its production, but a gentle southerly breeze, charged with humidity, will occasion a copious deposit. When the atmosphere has a temperature below the point of congelation, the dew, which might adhere to the substances exposed, passes into the form of hoar frost. It is also found that if the temperature of the earth's surface sinks during the night down to freezing point, the particles of water deposited become solid and form hoar frost.

A deposit exactly similar to dew is formed whenever the air becomes suddenly chilled, by touching any surface colder than itself. Thus the walls of long passages, vaults, or massive buildings generally, drip with wet during the early part of the summer, before the external warmth has sufficiently penetrated.

Leslie says:—"In fine, calm weather, after the rays of the declining sun have ceased to warm the surface of the ground, the descent of the higher mass of air gradually chills the undermost stratum, and disposes it to dampness, till their continued intermixture produces a fog or low cloud. Such fogs are, towards evening, often observed gathering in narrow vales or along the course of rivers, and generally hovering within a few inches of the surface."

In clear and warm weather the air is always drier near the earth's surface during the day than at a certain height above the ground, but it becomes damper on the approach of evening; hence, dew is always more dense on grass and low-growing plants than on the leaves of shrubs which stand up some feet from the ground.

Many substances are endowed with the property of radiating their heat, and of thus becoming cool with different degrees of rapidity, and it is found that those substances which in the air become cool first, also attract the most quickly and abundantly the particles of falling dew.

Dr. Wells in his observations on the deposition of dew found that grass became 12° colder than ordinary garden mould, and 16°·5 colder than a hard gravel-walk; hence we find that dew deposits the most readily on living vegetation, and that well-pulverised soils draw much more dew than those which have a hard surface, and are close and compact. Wherever the atmospheric air can freely penetrate there the depositions of dew under favourable circumstances take place. Sandy soils are powerful attractors of moisture, and on the sandy plains of Chili, where rain is scarcely ever known to fall, vegetation depends almost entirely on the nightly depositions of dew for its support.

It has been estimated by Dalton that the amount of dew which is annually deposited upon the soil amounts to about 5 inches, equal to more than 500 tons of water per acre. But the meteorological records inform us that the yearly rainfall on the eastern side of our island amounts to about 25½ inches, while 49 inches, or nearly double the quantity, is precipitated on the western side; and, as we find the rainfall varying considerably at different seasons and in different localities, so we know it is in the case of dew.

Steinmetz remarks that "the quantity of aqueous vapour in the atmosphere is greatest in equal latitudes on the sea-coast; it diminishes in proportion as we advance into the interior of a continent." In Algeria, at the stations on the coast, after the driest and hottest days, immediately the sun has set the soldiers' uniforms become wet with dew, and in a single night the blades of knives in the pocket become rusted, but at 30 miles from the sea night exposure is not attended with any inconvenience from the humidity of the air.

In countries near the equator the depositions of dew are much more abundant than in England, owing to the greater amount of heat absorbed from the sun during the burning heat of the day.

The quantity of vapour which the air is capable of holding in suspension is dependent upon the temperature, and we always find the atmosphere in the vicinity of currents of water more highly charged with moisture than it is in the uplands. In India the deposition of dew near the rivulets when all around is perfectly dry is said to be exceedingly marked. Colonel Sykes observes that "When in Poona in September and October, 1850, if there was no dew anywhere else it was found on the banks of rivulets and the Mota Mola river, but 15 to 20 feet from the water were the limits of the deposition."

Turning now to the composition of rain, dew, and hoar-frost, Boussingault has given the following analyses of samples collected at Paris and Liebfrauenberg in the year 1853:—

Table I.—*Showing the Composition of Rain, Dew, and Fog, in Grains per Imperial Gallon.*

			Ammonia.	Nitric Acid.	Total Nitrogen.
Rain	Paris		0·2100	0·0708	0·2808
	Liebfrauenberg		0·0350	0·0140	0·0490
Dew	Liebfrauenberg	Maximum	0·1310	0·0785	0·2125
		Minimum	0·0714	0·0030	0·0744
Fog	Paris		0·6000	0·7002	1·3002
	Liebfrauenberg		0·1790	0·0718	0·2508

It thus appears that in Paris the quantity of nitrogenous matter brought down in the rain-water is

six times as great as it is in the country (Liebfrauenberg), a result no doubt due to the ammonia evolved during the combustion of fuel and to animal exhalations; and to the same cause may be attributed the excessive quantity of nitrogen found in the fogs of Paris. We also observe that dew is richer in plant-food than rain, which may serve to some extent to explain its remarkably invigorating effect on vegetation.

Again, Lawes, Gilbert, and Warington have lately published in the *Journal of the Royal Agricultural Society* * the following analyses of rain, dew, and hoar-frost collected at Rothamsted, and determined by Dr. Frankland.

Table II.—*Showing the Maximum, Minimum, and Mean Amounts of Certain Constituents in Sixty-nine Samples of Rain-water, collected at Rothamsted, in parts per million.*

	Total Solid Matter.	Carbon in Organic Matter.	Nitrogen as				Chlorine.
			Organic Matter.	Ammonia.	Nitrates and Nitrites.	Total Nitrogen.	
Highest proportion ...	85·8	3·72	0·66	1·28	0·44	1·94	16·5
Lowest proportion ...	6·2	0·21	0·03	0·04	0·01	0·13	0·0
Mean, sixty-nine samples ...	33·1	0·90	0·19	0·37	0·14†	0·70	3·1

Table III.—*Showing the Maximum, Minimum, and Mean Amounts of Certain Constituents of in Seven Samples of Dew and Hoar Frost, Collected at Rothamsted, in parts per million*

	Total Solid Matter.	Carbon in Organic Matter.	Nitrogen as				Chlorine.
			Organic Matter.	Ammonia.	Nitrates and Nitrites.	Total Nitrogen.	
Highest proportion ...	80·0	4·50	1·96	2·31	0·50	4·55	8·0
Lowest proportion ...	26·4	1·95	0·26	1·07	0·28	1·66	3·5
Mean, seven samples ...	48·7	2·61	0·76	1·63	0·40‡	2·79	5·3

In the analyses by Boussingault of aqueous deposits collected at Liebfrauenberg we find that dews are twice as rich in nitrogenous compounds as rain-water, while at Rothamsted, from analyses made by Dr. Frankland by improved methods, nearly twenty years later, we find that these small deposits condensed from the lower stratum of the atmosphere contain on an average three or four times the amount of organic carbon, organic nitrogen, ammonia, and nitric acid found in the analyses of rain-water. The total quantity of solid matter and the amount of chlorides is also larger, but the difference is much smaller than in the case of the other ingredients.

It may be asked why snow and hoar-frost should be white? The question is a natural one, but the answer is easily given. If snow had been black it would have rapidly absorbed the sun's rays and been thawed by the first sunshine which fell upon it, the result of which would have been that vegetation, being prematurely deprived of that protection which Nature intended to guard it against the cold, would have died in the frosty air as soon as the sun had set. But the heat-reflecting and non-conducting "white snow" and "hoar-frost" are of the utmost importance as a protection against sudden alterations of heat or cold, for while it is melting its temperature never varies from 32° Fahr., and the plants which are enveloped in it rarely suffer a much lower, and cannot be exposed to a higher temperature. Hence we observe that frosts in spring or in early autumn generally do more damage to vegetation than the prolonged frost and excessive cold of winter, because the sun's rays act quickly upon the unprotected frozen plants, and by a sudden alteration in their warmth induce a change inconsistent with their vitality. Therefore gardeners during the winter season should take as much care to protect their plants from the sun's heat as from the frost's cold.—*F. F. W., Harpenden, February*, 1882.—*Gardeners' Chronicle.*

* Vol. xviii., ss., part i. † Mean of thirty-four analyses. ‡ Mean of four analyses.

TRAVELS OF PLANTS.

The wild plants of Peru and Chili were carried by the first explorers of those countries to Spain long before they grew in England or Ireland. Potatos were in Burgundy in 1560, and in Italy about the same time. In 1584 they were at Youghal, but it was not until thirty years later that they took firm hold of the ground in Ireland on their re-introduction at Youghal by Sir Walter Raleigh. Meanwhile Gerard, the herbalist, received from Sir Francis Drake some tubers, which he planted in his garden at Holborn. In 1663 the Royal Society published rules for the cultivation of the new crop. The Dutch carried the Potato to the Cape, and it passed into India in 1800, and has generally spread over the whole world, being confined in hot countries to the hills. The Potato recalls the memories of an age of travels and voyages, when Drake sailed westwards with his five ships, singeing the King of Spain's beard on his passage, and re-appearing to be dubbed Sir Francis after having circumnavigated the globe. The nation was at all times extremely curious as to foreign countries, and having become wealthy by means of trade and the growth of wool, it naturally welcomed travelled plants and introduced them in its gardens. In exchange for the Potato and two other plants, Tobacco and Cinchona, America obtained from this hemisphere Sugar, Coffee, and the Coconut.

A word or two on the Sugar-cane, a plant allied to the Indian Rattan, but in the estimation of schoolboys widely different in flavour—the one being bitter, and the other sweet. We pass over its early travels from its home in China, and notice only its passage into Spain with the Moors, into Madeira and Mexico with the spaniards, into Brazil with the Portuguese, into Barbadoes and Jamaica with the English colonists in the seventeenth century, and into Bourbon and Mauritius with the French.

The exchange of plants between America and the Old World includes Wheat and Maize, whose typical climates are widely different. It is the habit of Maize to commence its growth suddenly at a gallop in June. Wheat, on the contrary, prefers to advance gradually, and it breaks down with rust and mildew when forced on by an excess of sun, without a sufficient pause between seed time and harvest. Maize has been known to run its course in ninety days, and to reach the threshing floor to the tune of 160 bushels per acre. It is not surprising, therefore, that this prolific grain should have accompanied the colonists of various nations over the whole of America from Chili to the chain of lakes. It was introduced into gardens on this side of the Atlantic within fifty years of the first voyage of Columbus. It entered the Mediterranean by way of Spain, and before the death of Queen Elizabeth and her counsellors—two of whom were noted gardeners. It reached the Levant, where it became an important item in the trade of the Venetians. It afterwards passed up the Danube to Hungary, and travelling eastward with the merchandise o

caravans, it gradually entered the Rice countries, and reached China and Japan. Maize, however, is a native of temperate zones, and Rice of the tropics, consequently there are points where they part company. The latter does not find sufficient warmth in Europe north of the Alps; the former is at home in Ohio, Illinois, and the northern part of Kentucky, but in the Gulf States it finds too much heat. In the hot districts, where Cotton and the Sugar-cane flourish to perfection, it becomes magnificent in stem and leaf, and proportionately deficient in the ear or cob.

We will now take Tea. It has not been a great traveller as a tree, but the leaf ranges wide, and frequently passes twice through the teapot in company with any other small leaves resembling it in size. The first Tea was brought to England in 1666 by Lords Arlington and Ossory, who obtained it from the Dutch East India Company. Its original price was 60s. per pound. Fortune and other authorities describe the Thea bohea and T. viridis (green Tea) as varieties produced by the influence of age, soil, climate, and cultivation. Souchong, hyson, &c., are sorts which receive their names according to the time of picking and the age of the leaf and of the wood which bears it. Tea leaves, like grass in process of being made into hay, can only retain their green colour when quickly dried without oxidation of the juices by exposure in damp weather. Artificial green Tea is coloured by the use of indigo, gypsum, and Prussian blue, and being slightly poisonous, it has sometimes been known to "murder sleep."

The Paraguay Tea, so largely used in Brazil and neighbouring countries, is a Holly of restricted habitat, with properties, very similar to those of Tea.

The coffee tree is an indigenous ever-green in Arabia, where the berry remained locally unused till a Mufti of Aden acquired a taste for the beverage produced from it in Persia. In 1554 it was sold at Constantinople, where it had a remarkable effect in emptying the mosques in favour of the *cafés*. The berry travelled westwards in 1615 as an item in the Venetian trade. The *cafés* of Paris and the corresponding shops in London became fashionable at the end of the century.

To the preceding list of plants, which have been distributed by the industrious hands of man, we propose to add a few trees, placing first the Date—a Palm which has travelled from the confines of Asia through the Syrian and African deserts. Some of the finest plantations are those around Medina. Those of Egypt are important.

Two other equally important plants are the Banana and Plantain, tropical fruits which appear to be indigenous both on the Euphrates and the Orinoco. A patch of Bananas yields four or five times as much food as the same breadth of Potatos, and the tree grows from a sucker, bears fruit in eight months, and sprouts and fruits again in three months. It is therefore, a convenient tree for the tropics, and has been dispersed over them from the earliest ages. It will be remembered that the Bread Fruit of the Pacific—a tree producing fruit the size of penny loaves, yellow, sweet, and pleasant to the taste—was once set up in opposition to the Banana. The excitement on the subject culminated in London, in the idea of a crop of unadulterated bread growing ready baked in a large spreading tree of the Friendly Islands. George III. was accordingly petitioned on the subject, and the *Bounty* was sent out to Otaheite under the command of Lieutenant Bligh, for the purpose of securing some specimens of the important tree The *Bounty* reached her destination in 1788, and shipped 1,500 young trees, which were destroyed during the mutiny. A few years later Admiral Bligh received a similar commission, and succeeded in conveying the Bread Fruit to the West Indies, where the colonists soon discovered it to be inferior as food to the *foo-foo* of the Plantain, or Banana, while the tree itself is of slow growth.

Other food trees of the tropics are the Cacao, which cannot wander beyond the regions of great atmospheric heat and moisture; and the Dourian, the largest of tree fruits which Mr. Wallace enjoyed in the Malayan Archipelago. For the sake of naming the second largest tree fruit, we mention the Brazil-nut, whose woody fruit holds sometimes a quart of those angular and oily nuts. Circumstances prevent these trees from travelling far, but there are others to be briefly noticed.

The Aspen trembles all through Europe. It may have commenced its curious habit in the Caucasian range, where it is still a prominent tree, but historically it has always been dispersed over Turkey and Russia as far as the Frozen Ocean, and there is nowhere such a trembling of Aspen leaves as in the woods around Moscow, where innumerable seedlings sprang up after the conflagration of 1813. The Aspen is found in the bogs of Denmark at all depths, while the Alder, Birch, and Hazel do not occur below the Oak level. Like the Scotch Fir, therefore, it is one of the primæval trees of Europe. It is also a native of the woods of Invercauld, near Braemar, where it ascends to a height of 1,600 feet. It travels into Sutherlandshire, loves moist situations and woods, overhanging the Highland lochs. The margin of Loch Katrine and the islet of the "Lady of the Lake" are its favourite sites.

In the Highlands on the banks of the Dee and the Spay, in the pass of Killiecrankie, and everywhere in England, what tree is so bewitching in its beauty as the Birch of Russian pleasure-grounds, and of Siberian and Icelandic wastes? On the Apennines the Birch begins to grow at about 5,000 feet above the level of the sea, in Lapland it cases at a line 800 feet above the Fir, and 2,000 feet below perpetual snow. The Birch is the superlative tree as regards the extent of ground it covers, in Northern Europe, and in the variety of purposes to which it is converted in Lapland, where the natives sit in birchen huts on birchen chairs wearing birchen boots and breeches, with caps and capes of the same material, warming themselves by fires of birchwood charcoal, reading books bound in birch, and eating herrings from a birchen platter, pickled in a birchen cask. Their baskets, boats, harness and utensils are all of Birch—in short, from cradle to coffin the Birch forms the peculiar environment of the Laplander.

That fastigiate tree the Lombardy Poplar has been traced from Persia, where it abounds, and from the Himalayas, to the banks of the Po, and thence to the margin of our English steamers. About a hundred years ago Lord Rochfort imported from Turin the first cuttings of the Lombardy Poplar, which introduced here the novelty a pole clothed with foliage.

The Cedar of Lebanon is a modern tree in Europe. The oldest are, or were, at Chelsea, the tallest at Strathfieldsaye, the largest at Sion House. Lebanon is a wet mountain whose frost and snow equals that of Scotland; consequently the Cedar of Lebanon is adapted to the English climate and affects damp situations such as the banks of the Thames. It likes to dip its roots in running water for the purpose of absorption in dry weather. On dry soils it will be found a dwarf.

The introduction of the Cedar of Lebanon into France was an effort of most interesting devotion on the part of Bernard de Jussieu, who brought it from the Holy Land in 1737, and kept it alive on the voyage by sharing with it the very small quantity of water which he received during a prolonged [illegible]. In the absence of a flower-pot Jussieu is said to have planted the Cedar in his hat, and by giving it a moiety of his daily glass of water he succeeded in

keeping it alive, and afterwards had the satisfaction of planting it in the Jardin des Plantes at Paris. In 1838, at the age of 100 years, it was cut down, having attained a height of 80 feet.

The Elm, a wayside tree in Germany, a Vine-peg in France, and an ornament of several avennes in Madrid, is a puzzling tree to botanists, the genus being too mixed in character to reproduce itself true from seed. The Wych Elm is our only undisputed native, ripening its seed in our climate—the surest test of a native tree—and extending from the coast villages in Sussex to the haughs of the Teviot and Tweed, and even to the Highlands. All the varieties of the British Elms may be referred to this Ulmus montana, and to the old English Elm—Ulmus campestris—which has smaller leaves, throws up numerous suckers—not a habit of the Wych Elm—and sometimes displays a trunk of 90 feet long and 15 feet girth This is a constant tree of avenues and parks in the southern and midland counties, and of hedgerows in the valleys of the Thames and Severn. It is spread over Southern Europe, Western Asia, and Northern Africa, and it has been naturalised in England, where it rarely ripens its seeds, of which, indeed, only a portion ripens in France and Germany. The English Elm was rarely found in Scotland before the Union, and only on sites where it was known to have been introduced. It has been distributed over Ireland in modern times. Evelyn spoke of it as being rarely seen north of Stamford, and as having been imported from Italy by our great benefactors the Romans. Even Philip II. admired the stately form of our tree of lights and shadows, whose open foliage admits the light and produces "the checkered shade," which is the charm of woods. He had sat, perhaps, though not too often, with Mary—

"Under the shady roof
Of branching Elm, star proof,"

and on his return to a more congenial country he transported to the Escurial some English Elms.

Space will not allow us to add to this short selection of travelling plants, and we have therefore omitted the conifers, which have arrived from the East and West in this age of easy transit in numbers too great for enumeration. The same remark applies to the plants introduced by private firms, and to those collected by Sir J. Hooker and other naturalists.—H. E.—*Gardeners' Chronicle.*

THE PRODUCTION AND LOSS OF NITRATES IN THE SOIL.

Mr. Warington, chemist at Dr. Lawes's experimental farm at Rothamsted, in the course of a lecture at the Royal Agricultural College, Cirencester, gave an interesting account of the results of the investigations carried out in the Rothamsted laboratory, of which the following is a condensation.

Nitrates, Mr. Warington commenced by explaining, were produced as part of the living functions of a very low order of living organisms, bacteria, present in the soil; the action was analogous to that of the vinegar plant. the former supposition of chemists, viz., that nitrates were produced by mere surface oxidation, was proved to be erroneous. The conditions necessary to nitrification were, first, that the soil should be freely in contact with oxygen, for nitrification was a process of oxidation. Next, the soil must be moist—the more wet the soil was, the more would nitrification be assisted, provided the water was not so abundant as actually to choke the pores of the soil. Thirdly, the soil must contain some salifiable base for the nitric acid to combine with when it was formed, for if the base was not present, the process of nitrification would soon cease. In the fourth place, a favourable temperature was necessary. The process of nitrification would take place, it was true, at a very low temperature, nearly at freezing point—he had had it going on at 3° C. (37° F.)—but in a summer temperature, the process was wonderfully accelerated. The French chemists, by whom the discovery of nitrification as a vital process was first made, said that the most favourable temperature was about 37° C. (98° F.), when it would take place ten times more rapidly than it would at 14° C. (57° F.) The process went on most rapidly in the surface soil, and that for two reasons—first, because there was on the surface a greater abundance of nitrogenous organic matter, the remains of animal and vegetable life; and, secondly, the surface soil came more freely into contact with the oxygen of the air than was the case with the subsoil. The production of nitrates in the soil was a subject of very great agricultural importance, because scientific studies had clearly pointed out that, of all forms of nitrogen, nitrates were those most suitable for plant food; and in the case of cereal crops it had been established that nitrates were practically the only form of nitrogen which was adapted for the wheat crop, and on which it fed with advantage. Thus, the crop of wheat or barley to be obtained from the soil depended principally on the amount of nitrates which that soil contained. The subject became of new importance when they considered one of the properties of nitrates, viz., their great solubility, and their great diffusibility; in fact, for them the soil had no retentive power. With some other substances this was not the case—superphosphate, for instance, was readily retained, but for nitrate of soda the soil possessed no retaining power, and the permanence of it in the soil was at the mercy of the weather. It would, therefore, very easily slip through their fingers, and for that reason it was more worthy of their consideration.

From experiments on blocks of natural soil in the condition of bare fallow, it appeared that a considerable amount of nitrates passed into the drainage water. The amount of nitric acid coming through was very considerable about the month of July, the average of five years for that month giving the amount at 2·78 lb. per acre. In the month of August the amount increased to 6·68 lb. per acre. During all the autumn months there was a great deal more nitric acid coming through than in the spring months. That exactly followed what he had told them about the facilities afforded by summer temperature for the processof nitrification, for it was after the summer, when the autumn drainage began to flow, that they got the greatest amount of nitrates coming through. The average of the two sizes of drain gauges, 20 in. and 60 in. deep, showed that during the five years they had in one case 44·8 lb. of nitrogen per acre per year draining through the soil, and in the other case 42·6 lb. of nitrogen per acre per year. That was a very great amount of nitrogen to pass through the soil in the drainage water, and until those results were obtained they had no notion that such an amount would come away. An average wheat crop of thirty bushels per acre only contained 45 lb. of nitrogen, and here they had an average of 42 lb. and 44 lb. being lost by drainage, the highest amount in one year being 63 lb., and the lowest 28 lb. He would now tell them the amount of nitrates found in bare fallow. Samples of soil had been taken at Rothamsted, in two fields under bear fallow, of the first depth of 9 in, the second depth of 9 in., and the third depth of 9 in. In one field the whole of the 27 in. yielded 58·8 lb. of nitrogen per acre, and in the other the amount was 56·5 lb. But at the third depth of 9 in. they had not got to the end of the nitric acid, and no doubt, if they had gone still deeper, a further quantity would have been found. The greatest quantity of nitric acid was found in the second nine inches. They generally found that the

salts in the soil lay in bands, and it was very seldom that they were equally distributed throughout. The cause of the greatest quantity of nitric acid being found in the second depth was very simple. The nitrates were produced on the surface of the soil, and a few weeks before these samples were taken there had been a heavy fall of rain, which had washed them down. They saw that the results which he had mentioned really gave them the reason why bare allowing should be an operation calculated to so greatly increase the fertility of the land. In the early days of the Rothamsted experiments comparative trials were made, in adjoining fields, of wheat after wheat, and wheat after fallow. The first ten years of those experiments showed that the land that had borne an alternate crop each year after fallow had produced as much wheat in its five crops as the land that had grown wheat continuously had produced in its ten crops. They would understand how that happened when they observed the amount of nitrates found to be present in bare fallow; when the wheat followed a year's fallowing, it found two years' nitrates to feed upon. Of course the advantage or disadvantage of bare fallowing depended almost entirely on the weather, for in wet weather the advantage was to a great extent lost, owing to the nitrates being washed away, and removed in the drainage water. It was therefore a dry winter climate which made bare fallowing of value. He would next speak of the influence of a crop on nitrification. It was two-fold. First of all, they could not grow any crop on the land without diminishing the amount of drainage. The amount of evaporation from a field under crop is very much greater than from a field under fallow, and therefore the soil necessarily suffered less from drainage. The other effect was that the crop was eager to obtain nitrates, and therefore the nitrates were taken up by the roots, and turned into insoluble organic matter. He would lay before them the results of some determinations of the amount of nitrates present in cropped and fallow land. In 1878 they had at Rothamsted a field half in fallow and half in beans. After the removal of the crop of beans, samples were taken from that land, and also from the land under bare fallow. The first 18 inches of the soil that had been bare fallow contained 36 lb. of nitrogen per acre, and that from which the beans had been taken only contained 10·5 lb. per acre. At the same time a similar experiment was tried with land under fallow and land under wheat. The land under fallow yielded 33·7 lb. of nitrogen per acre, and that on which wheat had been grown only 2·6 lb. per acre. That was a striking instance of the extremely perfect manner in which the removal of the nitrates from the soil was carried out by the wheat crop. The drainage water from several plots of the experimental wheat field contained in the summer time no nitric acid at all, as it was taken up so completely by the wheat crop. They had now arrived at three cardinal points as regarded nitrates: (1) they were being continually produced, (2) they were very easily lost, and (3) that that loss can be prevented by a crop. This subject became one of very great agricultural importance when they saw the considerable money value of nitrates. Taking the present price of nitrates in the market, the loss by drainage of 44 lb. of nitrates per acre represented a loss of 37s. per acre per annum. That was a great loss, and it followed that economical farming depended very much indeed on the economising of the nitrates. Now, taking the various systems of cultivation, bare fallow involved the greatest risk of loss of nitrates, corn crops involved the next greatest, roots came next as causing a less loss, and lastly, pasture involved the least possible loss of nitrates. Why was this? They had seen that in bare fallow the loss was caused by the facility which the absence of crop gave for having the nitrates washed away. As to corn crops, their growing period was practically limited to three months, April, May, and June, but the process of nitrification in the soil would go on in July, August, and September with vigour, and the nitrates then produced were freely lost in winter, when there was abundant drainage, and no crop to feed upon them. If wheat was grown after wheat, there might be a considerable loss of nitrogen from the soil, from the fact that loss by drainage went on during a great part of the season when the production of nitrates was most active, and when there was no growing crop to retain them. When they came to the root crop, they had growth going on in June, July, August, September, October, and up to November, during the very period of the year when they most wanted to save the nitrates. Mr. Lawes deserved the credit of first pointing out that the roots in a rotation were a conservative crop—they saved the nitrates in the soil; when they were fed off on the land, the roots returned to the soil the nitrogen they had saved. In pasture they had the best possible conditions for saving the nitrates, for there they had vegetation on the land all the year round—they had the largest amount of evaporation and the smallest amount of drainage. Was it then possible to do anything to diminish the loss of nitrates? He believed that a part of the present agricultural depression was owing to the extremely wet winters of the past few years, which had resulted in lowering the condition of the soil by washing out extraordinary amounts of nitrates. Could anything be done to alter this? He was not a practical farmer, and he wished them to take anything he said on that part of the matter as subject to a much better opinion than his own. But he would point out a few things that might possibly be a help. For instance, in the case of a bare fallow, the good work on the fallow was done in the summer time—that was when they got the advantage of the fallow; and the evil came in the winter. A gentleman had told him that he had found it a good plan to get the fallows clean in July, to then plant mustard or rape, and then, before sowing the wheat in the autumn, to plough the mustard or rape (which had grown vigorously) into the land, and then to sow the wheat. Now that gentleman knew nothing at all about nitrates, but he had done just what he ought to have done if he desired to save them. The mustard or rape took up the nitrates, and turned them into insoluble organic matter, and when it was ploughed into the land, it slowly resumed the form of nitrates, for the nourishment of the wheat plant. But for that simple plan, a great part of the nitrates produced in summer might have been lost by the drainage of the winter months. Again, he thought there was no doubt—though he was aware that there was a great practical difficulty about this point—that it was not advisable to plough light land in the autumn. By ploughing land in the autumn they did their best to give vigour to the production of nitrates. They were also destroying the weeds, and in the winter the weeds were the farmer's friends, for they prevented drainage to some extent, and also helped by taking up the nitrates; and thus, if the farmer left the destruction of the weeds till spring, they were more or less equivalent to a green manuring. He would therefore recommend that no more ploughing be done in the autumn on light land than was absolutely necessary. Having pointed out the value of long-rooted crops, such as rape, mangold, clover, and sainfoin, which helped to bring up again nitrates that had washed down to a considerable depth, and thus make them valuable for plant food, he passed on to say a few words on nitrification in relation to manures. Experiments had shown, from observations made on the drainage water from a field in which ammonium salts had been applied to the wheat crop,

that the ammonium salts in a very short time became nitrified, and in one case a distinct increase of nitric acid was traced in the drainage water within forty hours of their application. In fact, as far as could be judged, the whole of the ammonia applied might be completely nitrified in a month. Another set of experiments showed that the application of nitrate of soda resulted in a still more striking increase in the nitric acid draining from the land. Seeing that nitrates found their way so quickly into the drainage water and were lost, it was of the highest importance to the farmer that he should not apply the costly manures which produced the nitrates before the crop was able to make use of them; and if they could only make sure of the seasons, they would be able to arrange their dressings accordingly. If they could anticipate a dry season, they would like to apply the manures in the autumn; while, if the winter was wet, of course a spring application of the manures would be preferable.—*Field.*

INDIA:—CROP AND WEATHER REPORT.

(*For the week ending 13th June 1882.*)

GENERAL REMARKS.—The monsoon has been progressing rapidly up the western coast, and most of the provinces which usually benefit thereby have received rain. Thus the Bombay Presidency, part of the Nizam's territories, the Berars, part of the Central Provinces, and the Central India and Rajputana States, record more or less heavy rainfalls. From the Bay of Bengal the monsoon is now gaining strength, and more or less rain has fallen in all parts of Orissa and the Central Provices, districts bordering thereon, as well as in all parts of Bengal Proper and Behar (excepting the Patna district and Durbhunga). British Burma too has received heavy rain. In Southern India the rains have continued heavy in Coorg, on the Malabar Coast, and in Travancore, and fair in the greater part of the Madras Presidency and of the Mysore State. In the Mulnad portion of Mysore, however, the fall has been heavy.

In Assam the southern districts continue to receive heavy rainfall, and other parts comparatively less. In the North-western Provinces slight rain has again fallen in nearly every district; and in the Punjab four districts have had rain.

General prospects are favourable throughout the country; crops, where on the ground, are doing well; and ploughing and sowing almost everywhere are progressing satisfactorily. These operations are, however, retarded somewhat in parts of the Mysore State, and in some of the southern districts of Bombay by too much rain. In the Madras Presidency two districts need more rain.

MADRAS.—General prospects good.

BOMBAY.—Rain throughout Presidency proper, heavy in the south, retarding sowing operations; slight fever and cattle-disease continue in a few districts; flights of locusts in Ahmednagar and Satara; cholera in Belgaum, Kaladgi, Satara, Ahmednagar, Ahmedabad and parts of Kathiawar: prices generally steady.

BENGAL.—More or less rain in all parts of the province during the week, except in Patna and Durbhunga; prospects everywhere very favourable; early rice, jute, and other autumn crops being sown; early sowings doing well; sowing of winter rice also commenced in some districts; sugarcane, indigo and other crops in the ground progressing; spring rice harvest almost finished, general outturn good; cholera much diminished; sporadic cases of small-pox and cattle-disease still reported from a few districts.

ASSAM (CACHAR).—Days hot and sultry, nights rainy; more than half of dumahi and murali crops sown; 2 cases of cholera reported from Lakhimpur; common rice 26½ seers per rupee.

MYSORE AND COORG.—Rain has fallen throughout the Mysore States; agricultural operations retarded in the Mulnad, owing to excessive rainfall; 4·54 inches at Hassan, above 3·39 inches at Chickmangalur; crops in good condition; prospects good; prices satisfactory; public health generally good; cholera continues slightly in the Yedattore and Ashtagram taluks of the Mysore district.

PICKLING ONIONS.—The *New York Tribune* states that the aggregate length of the onion rows on a pickle farm near Chicago is 320 miles.

PROTECTING THE BLOSSOMS OF FRUIT TREES.—Now that the time for taking action in the matter of protecting the blossoms of our choice fruit trees from the effects of frost, with a view to securing crops of fruit therefrom, is near at hand, a word or two respecting the next best material to glass for this purpose may be acceptable to those of your readers who may now, with this object in view be contemplating the protecting of their fruit trees, bet find it difficult to decide upon the best material with which to protect them. To those I would say, obtain from Messrs. B. Eddy & Co., Porthleven, Cornwall, the desired quantity of their No. 5 Web Hexagon Cotton Shading; it is made in three widths—54, 72, and 100 inches respectively—to suit walls varying in height, and is sold at 1*s.* 3*d.*, 1*s.* 8*d.*, and 2*s.* 6*d.* per running yard. The nature and make of this material render it more durable, elastic, and better adapted to serve the purpose for which it has been specially manufactured than any other material that has been had in use here or noticed elsewhere for a similar purpose, and for these reasons I think it is worthy of being noticed in the *Gardeners' Chronicle*.—H. W. WARD.

GIANT GRASS.—Last May, Messrs. Klunder and Co., Soerabaya, wrote to the Madras Government to say that they had forwarded a copy of instructions for cultivating "giant grass." This letter was communicated to the Superintendent, Government Farms, for remarks. The instructions referred to were, however, not received. The Superintendent reported that he had no personal knowledge of the grass in question:—"It is not an Asiatic species, but is indigenous in the region of country lying to the west of the Missouri River, United States, where it is found widely spread. Referring to this grass, in his report for the year 1870, the United States Commissioner of Agriculture wrote: 'The early pioneer, however, has already learned how soon the good native grasses are destroyed by the clipping and treading of domestic animals, and he sees with regret their places immediately occupied. . . *Panicum capillare*, *Panicum sanguinale*, &c., &c., worthless weeds and grasses that occupy the soil to the exculsion of every profitable production.' From this quotation, it would appear that the grass has not a good reputation in the country where it is indigenous. Of course, it is possible the grass may have since been improved by undergoing special cultivation and treatment. I cannot, however, recommend that Government should incur any expense in endeavouring to introduce the grass. At the same time, it may be worth while to get some seed and try it here. This I can readily arrange to carry out. I will also write to the Director of Botanical Gardens and plantations, Batavia, Java, with whom I am in correspondence and who, I know, will gladly afford any information in his power about the grass."—*Madras Times.*

TEA AND SILK CULTURE.—Mr. Ernest Tye, Secretary of the Italian Tea Districts Association writes to say that the wages of ordinary coolies in Assam, are five and six rupees per month, and not nine rupees, as stated by Mr. Cochran (*see ante*, p. 282). Mr. Tye adds that the cost of producing Indian tea in 1880, which ranged from 1s. to 1s. 3d. per lb., includes all charges for carriage, freight and brokerage, commission &c.—*Journal of the Society of Arts.*

COLA NUTS.—Some very interesting particulars are given on the West African trade in Cola nuts, the seeds of *Cola acuminata*. We are informed that the import of these seeds amounted in 1879 to 108,000 lb. more than in 1878. On the other hand, the export was 58,000 lb. in excess of the export in 1878 The trade in Cola nuts is an attractive feature in the ommerce of the Gambia. The Cola nut is the product of the Sierra Leone district, and the trade in it, both at Sierra Leone and the Gambia, is almost entirely in the hands of women, to a large number of whom it affords the means of livelihood, and in many instances the acquisition of coosiderable wealth. The nut is largely consumed by the natives of the Gambia ; it is of a bitter taste, and produces no exhilarating effect, but is said to possess the power of satisfying for a considerable time the cravings of hunger For this purpose, however, it is much less used than it is as a luxury. The trade in the article is rapidly increasing.

			lb.
In the year	1860	the import was about...	150,000
,,	1870	,, ,, ...	416,000
,,	1879	,, ,, ...	743,000

The trade in Cola nuts has also spread to Central Afaica, and even to the African shores of the Mediterranean The plant has been introduced from Kew to theWest Indies, Seychelles, Calcutta, Ceylon, Dominica, Demerara, Mauritius, Sydney, and Zanzibar.—*Journal of the Society of Arts.*

CULTIVATION OF FIGS IN THE COLONIES.—The *Colonies and India*, in recommending the cultivation of the Fig in some of our colonial possessions, points out that " Plantations have already been made in certain districts in Australia, but in all parts of that continent there is abundant opportunity for the extensive cultivation of the tree if only for the sake of its beautiful foliage in the treeless wastes in some portions of the interior. Of all the numerous varieties of Ficus scattered over the tropical and temperate zones, there is none more easily cultivated, none more striking in appearance, and none more profitable than the Ficus Carica. Its fruits eaten green or sun dried are both palatable and nutritious, and the enormous demand that exists for them is shown by the fact that the annual imports into Great Britain, chiefly from Southern Europe and the Levant, amount to over a thousand tons, while the United States import half a million dollars' worth yearly. According to the New York *Sun*, in Georgia, where the Fig bears two crops, an ordinary tree, six or seven years old, will produce 5 or 6 bushels of fruit annually, while twice or thrice that quantity may be expected from large old trees. There are trees in Eastern Florida that may be trusted to yield frou 20 to 30 bushels of Figs a year. At Santa Barbara, California, it is said that a tree ten years old will bear about 800 lb. of fruit a year. In Alabama it is considered the most prolific of all fruit trees ; and from Texas it is reported that the fruit succeeds perfectly all over the State. The tree is more hardy than is generally supposed, and if it will grow so well in tropical countries, and in the West Indies, in Fiji, throughout Australia and the greater part of New Zealand, in South Africa, in India—indeed, almost throughout our colonies and Indian empire. Figs ought to be a staple product. The ease with which the fruit is dried and packed is an important point in its favour."—*Gardeners' Chronicle.*

CALISAYA BARK —At a meeting of the Pharmaceutical Society on March 1st, Mr. Umney said that Mr. Gerrard had alluded to cinchona bark, and imagined that he could standardize it. He would assure Mr. Gerrard that great difficulties presented themselves, inasmuch as at the present time he believep it would be impossible to obtain in the London market a single hundredweight of flat calisaya bark which would come up to the Pharmacopœia standard. The requirement was, as they knew, 2 per cent of quinia. The flat calisaya barks, however, now present, would not probably contain more than 0·8 per cent of that alkaloid.—*Pharmaceutical Journal.*

A RAILWAY IN THE TREE TOPS.—The following paragraph, from a recent issue of the *Argus* of Petaluma, California, has lately been communicated to *Notes and Queries* :—" It may not be known outside of the neighbourhood where it is situated, but it is nevertheless a fact that in Sonoma County (Cal.) we have an original and successful piece of railroad engineering and building that is not to be found in the books. In the upper part of this county, near the coast, may be seen an actual roadbed in the tree tops. Between the Clipper Mills and Stewart's Point, where the road crosses a deep ravine, the trees are sawed off on a level, and the timber and trees laid on the stumps. In the centre of the ravine mentioned two huge Redwood trees standing side by side form a substantial support, and they are cut off 75 feet above the ground, and cars loaded with heavy saw logs pass over them with as much security as if it were framed in the most scientific manner. All roads lead to Rome except this one. The builders never contemplated a terminus at San Francisco, Petaluma, or Chicago, but merely to convey heavy timber from the woods to their mill. There are many places in our Redwood forests where this example might be followed profitably, as it would be cheaper to grade through with a cross-cut saw and lay the ties on the stumps than to remove the trees. We can boast of a broad gauge, a narrow gauge, and a road in the tree tops—yet we are not all happy."—*Gardeners' Chronicle.*

TEA CULTIVATION.—*India.*—The following statement, quoted from the *Madras Mail*, gives a striking picture of the progress made by this industry :—" In 1850, the area under this plant was approximately estimated at not more than 1,000 acres and the total outturn of tea at little over 250,000 lb. At the present time, the area under plant may be put down at 206,700, viz: Assam, 85,000 acres; Cachar, 47,000 acres; Sylhet, 18,000 acres ; Darjeeling and Terai, 31,000 acres ; Debra Doon, 4,300 acres ; Kangra Valley, 7,400 acres ; Kumaon, 4,400 acres; Chittagong, 4,200 acres; Chota Nagpore, 3,300 acres; producing about 40,000,000 lb. of prepared tea, and representing a capital invested not far short of fifteen millions sterling, while about two millions sterling are spent annually in India in the working and upkeep of the plantations. Of the advantages accruing to India—directly to the people, and indirectly to the Government—from the disbursement of so large an amount of money, there can be no question. It will be seen that, of the total area of 207,600 acres brought under cultivation, 150,000 acres lie within the administrative circle of the Chief Commissioner of Assam ; and the statistics of that province demonstrate the continuous and rapid progress of its revenue and general prosperity during the period in question—a prosperity which may be fairly claimed as being almost entirely due to the beneficial influence of the tea industry. There still remains, however, a vast field for future development, not merely in the production of tea, but for almost every kind of crop grown in India, more especially rice.—*Journal of the Society of Arts.*

MARKET RATES FOR NEW AND OLD PRODUCTS.

(London Price List, June 8th, 1882.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS. 1882.
BEES' WAX, White	Slightly soltish to good hard bright	£6 10s a £8
Yellow	Do. drossy & dark ditto	£5 a £6
CINCHONA BARK—		
Crown	Medium to fine Quill	4s a 6s per lb.
	Branch	2s a 3s
,, Red	Medium to good Quill	2s a 3s
	Branch	1s 6d a 2s
,, Twig		5d a 9d
CARDAMOMS, Malabar	Clipped, bold, bright, fine	6s a 7s
	Middling, stalky & lean	3s 6d a 5s 6d
Aleppee	Fair to fine plump clipped	4s a 5s
Madras	Long, lean, to fair	2s 6d a 4s 6d
Mangalore	Good & fine, washed, bgt.	6s a 8s
Ceylon	Middling to good...	2s 6d a 3s 6d

"NORTHERN AUSTRALIA.—THE RUMJUNGLE PLANTATION COMPANY LIMITED."

is the rather suggestive title of the Company proposed to be formed for the establishment of a plantation for tropical products in the Northern Territory of Australia. We have received an abridged copy of the Prospectus, from which we learn that the capital is to be £50,000 in 10,000 shares of £5 each, the calls being limited to 60s for a period of four years. The object is to cultivate coffee, cinchona and other tropical plants and for kindred purposes, and the provisional directors include men of standing and means in Melbourne and Adelaide, as follows:—

The Hon. John Colton, M. L. A., Adelaide.
S. Cornish, Esq., (Messrs. Harold Bros., Adelaide).
James Fergusson, Esq. (Messrs. Fergusson & Mitchell Melbourne).
Richard Guthridge, Esq. (Messrs. R. Guthridge & Co., Melbourne).
Robert Harper, Esq., (Messrs. R. Harper & Co., Melbourne).
John Marshall, Esq., (Messrs. Anderson & Marshall, Melbourne).
David Murray, Esq. (Messrs. D. & W. Murray, Adelaide).
S. Newland, Esq., M. L. A., Adelaide.
John Robb, Esq., Melbourne.

The mode in which the provisional directors have gone to work can be judged from the subjoined extract from the prospectus:—

The promoters, at their own cost, some months since, sent Henry Poett, Esq. (who has had upwards of 20 years' experience in Ceylon as a coffee planter) to explore portions of the Northern Territory with the view of ascertaining its suitability as to soil, climate, rainfall, &c., for the growth (chiefly) of coffee.

This gentleman has made a careful examination of several extensive districts, found land every way suitable for the purpose in the neighbourhood of Collet, Finnis, and Rum-Jungle Creeks, and accordingly selected for the promoters several contiguous allotments, and paid survey fees on 1,000 acres and the first year's rents for 2,793 acres.

The conditions for obtaining a crown grant are the further payment of sixpence per acre per annum for four years, and the cultivation within five years of one-half the area, or the payment of 7s 6d per acre, free of conditions of cultivation.

These selections are described as undulating and well watered, with a rich chocolate soil, are only three miles off the Government road to Southport, which is distant only 30 miles, and from which there is daily access by steamer to Palmerston—the chief shipping port of the territory.

On one of the selections an area has since been cleared and fenced for a nursery; the ground has been trenched, drained, and prepared for sowing; huts erected for labourers and seed of the most suitable kind has been ordered from Ceylon, so that advantage may at once be taken of the present season for sowing.

In the meantime cinchona (from which quinine is obtained) has been sown, and, according to late advices, is already appearing above the ground. This is a product in very large demand, and its value as a source of profit to the Company can hardly be overestimated.

To establish a plantation, and bring it into full cultivation will involve the expenditure of considerable capital, which it is proposed to raise by means of a public Company, to which the promoters will transfer their interest in 3,793 acres of land, and the improvements already made thereon, as at 28th February last, for a consideration of £1,000 (which sum has already been expended) to be paid in cash, and the issue to them of 1,500 shares in the Company paid up to £5 each, which will only participate in dividends at the same rate per share as others, and not according to the amount paid up on them.

But of even more interest to Ceylon readers as well as to would-be shareholders is the estimate which the ex-Ceylon planter, Mr. Poett, has put forward for the Company. It is as follows:—

Estimate made by Henry Poett, Esq., of the expenditure on and returns from a plantation of 1,000 acres, of which one-half will be under cultivation with Liberian coffee, and in bearing in four years:—

Cash to be paid for promoters' interest in 3,793 acres and improvements ...	£1,000	0	0
Fencing, buildings for managers and labourers, implements, tools, working plant and stock	2,600	0	0
Clearing, trenching, draining and planting 500 acres in four years	5,200	0	0
Cost of importing coolie labour—wages, provisions, &c., in four years	4,000	0	0
Salaries—Manager and assistant and other establishment expenses in four years	4,400	0	0
Repairs, replacements, maintenance, &c.	3,000	0	0
Contingencies	1,000	0	0
Total expenditure in four years ...	£ 21,200	0	0

At the end of the fourth year the first crop would be ready for gathering, estimated to be of the value of £3,500 at the plantation.

In succeeding years the trees being in full bearing would yield a return of £12,000, and the annual cultivation and establishment expenses would amount to about £6000.

From these estimates, which have been very carefully prepared, it will be seen that in the fifth year, when the plantation is in full bearing, it will yield a net profit of 20 per cent. per annum on a paid-up capital of £30,00, which is in excess of the anticipated outlay.

At this time also—that is, at the end of the fourth year—the cinchona trees, of which there would be many thousands, would be ready for barking, yielding from 2lb. to 3lb. of bark per annum, and of the value in the first year of 4s. per lb. As the trees become older they yield a greater weight of bark, which also is richer in alkaloids, and therefore of greater value per lb. The market value of this produce varies from 2s to 15s per lb., according to its strength.

We ought to know something about plantation "estimates" in this colony, but the conditions under which Mr. Poett has prepared his statement are so different in many respects to those prevailing here, that it is not easy to criticize his figures. It is, evident, however, that, apart from the cheapness of the land, Mr. Poett's expenditure would be considered very liberal in Ceylon; for the cost of bringing some 500 acres of land into full bearing with Liberian coffee is put down at close on £40 per acre. Nor can it be said that the estimate of the return of £12,000 from 500 acres of such coffee is too high, provided the plants grew and produced as they have done in Ceylon. But we question very much whether the dry Northern Territory of Australia will ever show a plantation carrying as much as 6 cwt. of coffee per acre over 500 acres. The experiment has to be made however, and although, in the Palmerston Experimental Gardens, coffee, tea and cinchona have not been very successful, the proposed plantations are on better soil and higher ground. As regards cinchona the Director of the Gardens seems to have given a decidedly adverse opinion which has called forth the following letter from Mr. Poett to the Melbourne *Argus*:—

SIR,—The special correspondent of the *South Australian Register*, in his last long and interesting communication to that paper, expresses the opinion, formed on Mr. Holtze's utterances, that cinchona will not succeed in the Northern Territory of South Australia.

Mr. Holtze is reported to have said: "It is all very well to say it thrives in Ceylon, but there are high mountains there; we haven't got these mountains." As I am endeav-

During to promote the introduction and cultivation of all tropical plants in this territory, and, as I have publicly expressed the opinion that cinchona will thrive there perhaps you will kindly permit me to answer Mr. Holtze in a very few words—words at which I trust he will not take any offence. I had the pleasure of meeting Mr. Holtze several times, and went over the gardens twice with him, and I have every respect for his ability, industry, and truly gentlemanly disposition; but differences of opinion will exist, and, I am sure, no one would be better pleased than Mr. Holtze himself to find he was mistaken, and that cinchona will succeed in the Northern Territory.

Although there are mountains in Ceylon upon which cinchonas flourish, it is equally true that many thousands of trees are successfully grown at an altitude of only from 100 to 200ft. above the sea in that little island.

In Ceylon the higher altitudes are chosen in place of the lower, not only because the more valuable varieties of cinchona thrive better there, but because the climate in the former is more suited to the European constitution. I do not deny that a higher elevation than that obtaining in and around Palmerston would be preferable, but I am quite at issue with Mr. Holtze when he so unhesitatingly condemns the enterprize. Unless he has considerable experience in the cultivation of cinchonas, he should be very chary of giving utterance to an opinion adverse to the probable success of so interesting and valuable an industry as would be developed, if chinchona be successfully grown. An opinion coming from him will doubtless have great weight, and should therefore be only given after very mature deliberation. It is quite a mistake to suppose that cinchona seeds are peculiarly delicate and hard to rear. They are more often destroyed by over attention than by neglect. Those who have not had a varied experience, in rearing these little seeds are very apt to smother them with too much and wrongly-timed attention; hence the number of failures. This may have been the case with Mr. Holtze's seed, or it may have been too old, or too green, or immature. In any case, methinks it was premature to condemn the industry because (I write under correction) one small batch of seed failed.

I have in my time planted great quantities of this seed, and grown millions of plants under different conditions, and I am convinced that certain varieties will grow very profitably in North Australia.—I am, &c.,

HENRY POETT.

6 Apsley-place, May 10.

The cinchona nursery on the Rumjungle plantation is said to be getting on well, but it is evidently too soon to speak of success. A moderate account of success there may be, but certainly coffee and cinchona are not the products we should single out as most suitable for the territory in question. To judge by the accounts we have seen published of the country, its soil and climate, sugar, tobacco, cocoa and indiarubber are the products we should look to chiefly; but then we have not been over the land, and Mr. Poett, a practical planter, has, and he ought to know something of the conditions suited both to cinchona and Liberian coffee.

CEYLON: GENERAL PLANTING REPORT.

(From a Planter North of Kandy.)

COFFEE (ARABIAN AND LIBERIAN); COCOA; CINCHONA; TEA; CARDAMOMS.

I trust the readers of the *Observer* will pardon me, if I occupy some space in the columns of that valuable journal in reviewing the position of the planting enterprize, and in dealing with the various products that have assumed such proportions since the advent of leaf-disease has crippled our once-flourishing staple. One cannot avoid being struck with the wonderful energy and intelligence with which the Ceylon planters enter upon new cultivations, and improve on methods that have long satisfied planters in other countries. The reason is just this: that the body of men average above any other body engaged in a particular branch of cultivation anywhere in the tropics. For instance in 1879 Mr. Andrew Nicol made the first experiment in Ceylon* in shaving cinchonas, and now how largely has that method of harvesting developed. It has opened out a very large field in obtaining paying returns from cinchona never dreamt of in the old coppicing days. And so in everything else. Ceylon men have proved themselves equal, if not superior, to scientific Government officials, in attaining practical success. I will now go over the different products now being cultivated in Ceylon with remarks on each, which I put forth in all diffidence and modesty.

I. ARABIAN COFFEE.—To one journeying through the coffee districts in the month of May 1882, the abundance of wood and the absence of crop inevitably prove that, without leaf-disease, coffee would still give paying crops as in days of yore. At present we are growing wood for bumper crops of *Hemileia* spores! Most of the money spent on weeding and pruning and other works is spent to provide food for the speedy maw of leaf-disease. The ever-hopeful planter looks on his fields covered with fresh foliage, and tries to deceive himself that he has lots of wood for *next year*. Yes; next year's crop of what? Leaf-disease, and so year by year till our hearts are verily sickened. It would merely be folly to attempt to fatten and nourish a diseased man, unless the disease itself is eradicated. Therefore the question arises: "Why go on cultivating this product that has become unproductful?" This is not a financial crisis, nor a market crisis, that has overtaken the colony, but the sure result of the presence of a fatal disease in our coffee. The end I would say is sure.† All attempts to fight the disease have been baffled, and we have had the greatest scientific authorities diagnozing on the case.

II. LIBERIAN COFFEE.—Here is a brighter, more hopeful aspect. As surely as is the decline of the other coffee, so surely is the rise of this into favour as a successful product. It is the opinion of some that a certain jealousy lest this might prove a dangerous *rival* to the old staple has caused Liberian coffee to be looked upon to a great extent with prejudice. But there can be no *rivalry* now. In Kalutara, Kurunegala, Polgahawela and Dumbara, this product is being largely and extensively cultivated. There is ample scope in the moribund district of Morawak Korale and in many parts of Sabaragamuwa. The Liberian plot on Stubton estate in Rakwana shows what that plant can do when carefully cultivated. Then round by Passara and Badulla-Teldeniya and round by Bintenna to the Mahaweliganga rapids up to Dumbara, there are thousands of acres available for Liberian coffee. To illustrate the obstructiveness of Government, I understand that an application for land was made some years ago by two planters for the cultivation of Liberian coffee near Bintenna resthouse, and that this was refused by the Kandy kachcheri for some red-tape reason. There is a large acreage of land round by Nitre Cave and Laggala at low elevations suitable for this product, and also surely in Matale, which finishes the round of the low districts. Near Galle, Mr. Dobree is, I hear, very hopeful as to the prospect of success of Liberian coffee on the Company's land. I expect the product will prove a worthy successor to its smaller and choicer cousin. The pruning of Liberian coffee differs considerably from that adopted with regard to Arabian coffee. Secondaries and tertiaries, thrusting themselves upwards and back-

* Nonsense.—ED.

† This view is not consistent with the fact that coffee as badly afflicted with the fungus as any in the country, has of recent years borne heavy and profitable crops.—ED.

wards, should be tied down, and so trained to the horizontal position, instead of being pruned off. Plenty of wood is desiderated, as this plant requires shelter for its berries; bears in the green wood; and is chary of throwing out shoots at the eye of a cut-off branch. The result of pruning a Liberian coffee tree, in the same way as you would an Arabian, would be that the former would become straggling and "whippy," instead of round and bushy, and moreover would give only a few berries at the tips of the branches. If your correspondents find their experience differ, I trust they will come forward with their criticisms. As machinery is in use to pulp and cure this variety, there is nothing calling for a remark here. Leaf-disease no doubt is present; but the vigour of the tree, as well as the stoutness of texture of its leaves, will I think, prevent it from suffering to anything like the extent of the Arabian kind. No doubt the question of leaf-disease has also been the means of preventing the free extension of this product.

III.—Cocoa.—The chief attraction of this product is that it is permanent. I believe that a cocoa tree is considered in the West Indies to have reached its prime at its sixtieth (60th) year! So that the planter makes provision not only for his own lifetime, but for that of his children's. The undoubted success that has followed the cultivation of this plant, in Dumbara especially, is patent to any casual visitor to the valley. The returns are not so rapid, as it is the fashion for Ceylon men to hunger after; but the slowness does not detract from the sureness of future profit. It is just this "hungering after" rapid returns that has landed so many high and dry. When the trees have developed into their full proportions, and heavy picking is the order of the day, then some plan, differing from that adopted with regard to the small coffee berries, will have to be resorted to. The usual present plan is to cut off the ripe pods with an implement combining a hook and knife, taking care not to injure the excrescences on which future crops depend. The blossoms appear on these excrescences, and by tearing off the pods injury and loss occur. The pods are emptied of their contents by a coolie armed with a sharp knife, with which he half twists and half cuts the pod at the stalk end, and then the bunch of seeds comes out easily. These wet seeds have great specific weight, and therefore the carriage to the store, in the absence of carts, involves expense. These seeds are emptied into ordinary coffee cisterns lined at the bottom with wire-gauze placed on reepers for the purpose of letting the juice drain off. On the top is laid a covering of plantain leaves, and then a covering of sand, and then over all are laid old sacks. This is left thus for about twenty-four hours, and then the seeds, having been fermented, are dried rapidly, either in the sun, or, should the weather be uncertain, in heated air. The nibs (the articles of commerce which are contained within the shell of the seed) are peculiarly susceptible to mould. The last shipment from Pallekelly, which reached such an unprecedented price, and which was termed by the brokers "highly dried," was, I understand, exposed to high temperature by the Clerihew process. One authority advocates hot water or hot air pipes, instead of a hot air draught through the room. As to pruning, reverse the Arabian coffee method, viz., keep on old wood, and keep down young wood. Of course this admits of modifications. The thing to be desired in a cocoa tree is a thick solid crown as compact as possible, so that the leaves shelter the young fruit. Cocoa is very sensitive to wind. It seems to luxuriate in the direct rays of the sun, but suffers from wind immediately. Therefore shelter, not shade, is required. In the West Indies the pods are heaped on the ground in the field for twenty-four hours before being opened. I should say that this would render the pods soft, and lessen the danger of damage by a sharp-edged instrument. Some would reply: "Thieves might appreciate the heaps of ready-pulled fruit." In answer, I say that it does not make much difference whether the fruit be on the trees or on the ground. Mr. Vollar and Mr. Sinclair especially, along with others, deserve great credit in that they have brought the successful cultivation and curing of this most delicate product out of darkness into light, and, though more light may be wished for, yet the success has been very wonderful. Ceylon, generally, is not suitable for this product, but the experience gained here will be available for other tropical countries, such as Sarawak, New Borneo, and other lands, possessing richer soils than our island. There are some trees of the yellow variety, and also of the green or white variety, on Pallekelly. The coolies distinguish them as the "tangam choklat." These are bearing heavily, and present a very pretty sight, with the pleasant contrast of the golden-coloured fruit amongst the dark heavy foliage. These are of a more robust and spreading character, and will, I should think, bear more heavily than the red variety. I do not know if they would fetch a better price. There is nothing more pleasing to the eye than a *cocoa walk*; but, what is better, there are few things so filling (as regards the purse) at the price. I must not omit mention of the success that has crowned the efforts of Mr. Forbes Laurie in this product, and also notably in Liberian coffee. So much so has his success been apparent, and his pluck and enterprize been recognized that planters know him by the name of *New Products*. We all wish *New Products* all success in his various ventures.

IV. Cinchona.—I feel myself unfitted to give adequate justice to this subject. There are many points connected with the cultivation, which belong to the botanist, and the chemist, and on which the greatest authorities differ.

This paper makes no pretence of going deeply into any subject, but is merely a review of different products. It was said in India that sufficient seed had been sent to Ceylon to cover the entire surface of the Central Province. I would venture to say that many hundred-weights of cinchona seed have failed. Still Ceylon planters were not daunted. Slowly but surely progress has been made; and, had it not been that the financial pressure has caused many to cut down their cinchonas, this product would have been more visible to the eye of one journeying through the different districts. Hard-up proprietors have had to kill the golden egg-laying goose. But new methods have since been discovered, whereby the goose may be induced to increase her produce without being slain. How bitterly do many repent the coppicing and the uprooting of their cinchonas in these days of shaving; but still those quills of bark gave a buoyancy to the sinking ship, and staved off the evil day to many a desponding planter. I do hope the evil day will never come, but that the turning in this long and dreary lane is near. I do not enter the disputed ground of nomenclature, hybridity, or classification. Suffice it to say that it is best to ask with Shakespeare "What's in a name?" and, leaving scientists to fight for their favourite theories, pursue steadily the cultivation of those kinds that have been already tested by the market and laboratory, as being the most profitable. Succirubra, and a hardy form of officinalis (whether called condaminea or not) have been proved to be the best paying of the common kinds. Ledgeriana stands by itself, above all doubts and dissensions, as one of the most valuable products in the world. Great progress has been made in the extension of this priceless variety. A great deal of seed from India and Java has been obtained, from which many valuable clearings will now be planted up. The results of analysis with regard to this plant have been most wonderful, and have equalled anything effected

in Java or India. Such names as Christie, Roberts, Wm. Smith and others are creditably connected with the cultivation of this prince of products. Mr. Wm. Smith has achieved marked success in open-air grafting that has proved of more value than the methods of Government scientists, and will no doubt prove a most important money-making cultivation of itself—I mean the grafting and propagation of Ledger plants.

The dying-out of cinchonas results from the following causes :—

(1) Bad seed, from which plants are raised, and afterwards languish and die through want of stamina of constitution in the plant.

(2) Planting in hard cabooky land, into which the roots of the cinchonas fail to penetrate freely, with the result that the growth is retarded, and eventually checked altogether.

(3) Planting in virgin land, with clay subsoil and wet climate, where the cinchonas grow surprizingly well at first, stimulated by the top humus and the moisture, but where the mortality is serious and sudden in the second or third year, owing to the roots penetrating to the sour clay beneath.

(4) Planting in watersheds, *i. e.* in valleys which are the source of streams on the ridge of a mountain range and full of slab bed rock and innumerable springs.

(5) Planting out immature seedlings placed in the ground by a chip of the mamoty, and left to themselves to fight their way in the world.

(6) *Using rich mould and manure for the nursery beds*, thereby producing a plant full of forced vitality, which vitality slowly but surely retrogrades when brought in contact with the ruder soils of the mountain-slopes.

(7) Canker. But, in mentioning this, I would state my belief that it results from the above causes—one or all of them—and is only another word for "dying out." It is a result rather than a cause.

I disagree with those who say drainage will prevent dying out. Holes, either above or below each tree, or close surface drains, have hitherto generally failed in baffling this mortality when it sets in. Let those with good deep soil and thriving nurseries take heart of courage, and not fear canker or "dying out." Drainage will modify certain evils resulting from surface wash; but that is all. The best way to avoid canker is to choose suitable land. Make your nursery with sand and "spoil" of roads in equal parts ; water regularly and moderately ; pick out carefully under fern ; reduce shade till the plants can remain naked in any weather ; don't plant these out till they are six to ten inches in height, and have been exposed to all weathers a month or two; put them out in one-foot holes into which the top-soil has been carefully filled, and see that care be taken in arranging the roots; plant in "April" weather, that is, alternate showers and sunshine, *without* shade ; or with very temporary material to last a few days only; keep the collar of the roots near the surface, and prevent the weeders from heaping rubbish round the plants:—exercise all this care, and you will be rewarded in having fine cinchona clearings ; but remember that it may all be thrown away, if your land be unsuitable : that is the chief point.

Some say, "Lop your trees"; others, "Don't lop at all." The medium I think is the best ; but it must be done with a view to future shaving. So in lopping it is best to leave a piece of a branch which will form a step, as the shaving operations extend beyond the reach of a a cooly. This stump of branch sprouts freely ; so there is no fear of its dying off. I think the earlier shaving is begun the better, after the tree's second year. Some shave during the second year, and, perhaps, they are right. The majority advocate covering the shaved stem with some material, such as mana grass, plantain leaves, wild cardamom or ginger leaves, or even with the leaves of the cinchona itself. The first-named is best, if within a conscionable distance. They say that, if you do not cover the bark, the alkaloids do not increase ; that any breach of the cambium spreads as the bark renews and grows ; and that often fatal injury to the tree results. It is safer to cover, and does not cost much. I do not wish to enter into details, such as cost and tasks ; but there are many who can give us reliable figures. In lopping, the barking of the branches has to be considered. The old method was scraping off the bark with a knife at a great cost. Now the papers are full of new "dodges" and machines for peeling twig. I would say that the simplest is the best. Bottles, alavangas, old mangles, bits of sticks, are all used, showing that a good deal of twig bark is being harvested. There is great room for improvements on the spoke-shave. There are one or two, but I have not seen them. Uprooting, coppicing, stripping ribbands of bark with mossing, are obsolete systems to the pushing planter of Ceylon. Dr. Trimen, Mr. Moens, &c., &c., are all in the back eddy ; and Ceylon planters are at work, with their mangles and alavangas, down the full stream of enterprize and success.

V. TEA.—As the last heading has occupied so much room, I must deal with this as my space will admit. The speculator, the greedy hungerer for returns, the Galle Face planter, need not have anything to do with tea. We want capital and careful work to effect slow but sure returns. Ceylon tea is assuming an honourable place in the world's markets ; and, as we get to understand more about it, it will prove a favourable and profitable investment for capitalists. There is more assistance from machinery in this than in any of the other products. An easy way of concentrating operations, and, at the same time, of extending the acreage under tea, is by central factories being established and presided over by a skilled tea-planter ; by these factories purchasing green leaf at a reasonable cost from surrounding gardens ; and by their also importing machinery which will enable them to pay the grower of the leaf remunerative prices, and to put the cured article in the market at the lowest possible cost with the highest possible sale-prices. They also would give employment to many ex-coffee-planters in field work, which would differ but slightly from that on a coffee estate. Then the Uva railway could bring down unlimited *timber* to the central saw mills, in which tea-boxes could be manufactured by machinery. I see a very wide field opening out; but capital must come first. Never for one moment listen to the croakers who look at things with their telescopes reversed, and narrow down the future of the country as their hopes of rapid fortunes fail to be realized.* I have heard it said :—"The worst of tea is that it will grow well anywhere." That may be taken to mean that one is tempted to push it in all climates and at all elevations because it grows, without making sure whether it will "flush to pay" : also that, should everyone "go into tea," the market would be overstocked. That fear has never been realized in Ceylon with regard to any product. Ceylon will never upset the world's markets with any produce. Tea-growers in Ceylon are deeply indebted to Mr. A. M. Ferguson : there is no doubt at all about that. The results will now make themselves felt ; and a great rush for tea may be looked for in Ceylon in a few years. Let the discontented, the useless, the drones, be drafted out, and let the steady young fellows wait for the coming wave that will bear them right up on the heights of fortune,

* And yet our correspondent's first paragraph leaves the reader to infer that he recommends the abandonment of 250,000 acres of Arabian coffee !—ED.

not dreamed of in these dark days of trouble. It 's bound to come, and I think "Tea" will be the chief agent in restoring prosperity in Ceylon—not a high-pressure, unwholesome state of things, but a solid, lasting prosperity. I do not profess to deal with tea, save in a broad sense. I am not a tea-planter, and I touch not the mysteries of withering, rolling, firing, fermenting, &c., &c., because I have a notion that machinery can do most of it, and there is no good in giving hints to a machine.

VI. Cardamoms.—This is a choice thing. A planter's idea of bliss should be 50 acres of cardamoms and 50 acres of "pucka" ledgers. £3,500 a year from the former, and what wealth shall I put down on account of the latter? It is unspeakable. It takes away one's breath. Let us softly enter and peep at the stores of wealth. 50 acres of jungle will cost £20 an acre to *bring into bearing*. That is £1,000. The returns after that *nett* £70 an acre with the above result. Away with sinna durais, conductors and kanganies. Let us, with our wives, sisters, daughters, sons and brothers, cousins, nieces and nephews, recline beneath the graceful fronds of the cardamom, and amid the cool fragrance from the precious fruit, as it is daintily picked, converse amicably together and dream of wealth. In Nitre Cave, Rangala, Medamahanuwara, Laggala, Matale and the Knuckles cardamoms fruit splendidly. In the neighbourhood of Ambagamuwa they grow freely but do not bear heavily. A beginning has been made in Balangoda and Kukulu Korales, but there is hardly time yet for results A great rage is beginning to set in. Mr. George Porter, an authority in this cultivation, made good use of his time at home. There are several kinds of cardamoms :—

(1) The Ceylon wild cardamom. This would certainly pay and deserves attention. It is very plentiful in the jungles of Nitre Cave, Ambagamuwa, and Kukulu Korale, &c.

(2) The Malabar cardamom. This is a very small but choice fruit, growing like the above in *racemes* along the ground, bearing heavily in suitable localities.

(3) The Mysore cardamom. Dr. Trimen should come up to Medamahanuwara or its neighbourhood, and thus find out whether this variety does not deserve more distinction (in both senses) than he chose to give it in his last report. The species is distinct. The *racemes* grow perpendicularly among the bulbs of the stool and the under surface of the leaves is smooth, whereas in the Malabar kind it is hairy. The Mysore cardamom is very robust and vigorous in habit, its stools reaching to large dimensions, and its growth surpassing that of other varieties. The fruit is large and round, whereas the Malabar is small and round, while the common Ceylon kind is large, elongated and flattened. The flavour of No. 1 lacks both strength and flavour ; in that of No. 2 flavour predominates over strength ; while No. 3 excels both of them in strength and the former only in flavour. Authorities are against propagation by seed. Bulbs of a good size are best. These are put out singly or in couples at seven to ten feet distance apart, in a clearing prepared for them, by felling most of the jungle, save so much as is requisite to break the full glare of sunlight or daylight. Very little shade is necessary ; indeed some believe that with the robust Mysore no shade is necessary. Fairly rich, moist, rather spongy ground is best ; steep dry hillsides are not suitable. If the bulbs are near, it is not necessary to stump them. Put them in slantingly with their heads uphill and not too deep. I have said propagation from seed is bad ; therefore it will be inferred that it is not advisable to use plants. A plant becomes a bulb about the first year; but bulbs from old stools are the best.

As to picking the fruit, the ripe capsules are distinguished by their slightly paler colour, and by the blossom stalk withering back to the fruit. In the Malabar variety, ripe capsules are known by coming off easily at the touch , but that is of no use, as all capsules have to be clipped off with special scissors. These capsules have then to be well dried, both in the sun and in a room in which the temperature has to be kept up to a certain height. One planter is said to have discovered a sure method of obtaining a very clean sample, which fetches a higher price than other samples. Some mystery is attached thereto. Some hint that lime is employed ; others bleaching powder, or chlorine ; but I believe that what is used is nothing more or less than what the doctor recommended to his dirty patient afflicted with skin disease—*soap and water*! ! I may be wrong, but I think I am right. A pale straw-coloured tint, not a white or soiled appearance, fetches the highest prices. A cardamom room is a pretty sight, with its rows of light shelves for the movable cardamom trays. It is a nice occupation, and could be superintended by the manager's wife. Ladies have not enough to do, and gentlemen in this country monopolize the gossip ; so cardamom-curing would be appreciated by an energetic, intelligent wife. [So that of the cardamom cultivator as of the Western farmer, it may be said that he cannot afford to remain single !—Ed.]

There is another species found in the jungles, which differs very much from all the others. It is stunted in habit, with large leaves which are hairy, like the Malabar, beneath. The fruit does not appear on *racemes*, but in close clusters near the root. The flavour is poor.

Cardamoms can be combined very easily with cinchona ; for, when the cinchonas grow up, and are being subjected to the spokeshave, cardamoms can be planted under their shade. Suppose the cinchonas to be ledgers, and think it out, whether this condensed method of gardening, with its large returns and small amount of labour, be not a preferable investment to a wild goose chase over the mythical gold reefs of Southern India. Capitalist ! the above is true and surely it is tempting. Adieu to the wasteful, straggling, ponderous, high-pressure coffee estates. Give me a bungalow containing every comfort and æsthetic enjoyment, and adjoining let there be the ladies' cardamom house filled with the dainty perfume of precious spice. Farther off the cinchona store heaped with scrapings from the rich ledger stems ; and, along a well-swept path, let us pass, and visit the cardamom field, which is softly shaded by the foliage of the cinchona ledgerianas. As for other products, such as rubber, black pepper, cinnamon, vanilla, cloves, tobacco, &c., &c., I do not notice them, because their cultivation has not reached an appreciable importance. But there is one source of rich harvests, derived not from fruit, leaf, flower, bark, or sap, but from the bowels of the earth : that is *gemming*. But unless gemming is carried out wholly by the hands of Europeans—unless natives and immigrant Tamils and Moors are totally excluded from operations—no hope of returns can be confidently expected. That untold wealth lies hidden under foot of man round Kukulu Korale, Rakwane and Bambarabotuwa, and in other places in Sabaragamuwa, is certain. That the methods of the natives and Tamils are crude and primitive in the extreme, and are capable of immense improvement in the hands of Europeans, is also a fact. Capitalists should give their attention to this. I do not for a moment believe that gold-seeking will pay in Ceylon. It is a forlorn hope, and will soon lapse into obscurity.

I trust the above notes will be worthy of a place in the *Observer*, and of a perusal by its readers. If they should raise any discussion, or afford any one assistance or knowledge on any point, the writer will be content. Aberdonensis.

HYBRIDS AND CROSSES: DEVELOPMENT AND RECUPERATIVE POWERS OF CINCHONAS.

Mr. Gammie, without, so far as we are aware, having seen Mr. Baildon's recent book, holds that what is called Assam *hybrid* tea is not a hybrid at all, but simply a cross between two varieties: the indigenous tea of the Assam jungles and the cultivated tea of China. He considers the parent plants as but differing forms of the same species, and we feel strongly inclined to believe that he is right. Yet the large-leaved *tree*, *C. succirubra*, is scarcely more different from the generally small-leaved and shrubby *C. officinalis*, than is the large-leaved one-stemmed tree-like Assam tea from the small-leaved China, with its numerous stems and low bushy habit. What is called the Assam hybrid (an undoubted cross between the tree-like Assam tea and the bushy China) is perfectly and apparently permanently fertile, and, instead of combining the bad qualities of both parents, as Mr. Broughton rashly asserted of Mr. McIvor's cinchona hybrids, it is really superior to either and both; being, in open cultivation, less delicate than the indigenous Assam, and more luxuriant in size and quantity of leaf than the China. Now, if what is known in Ceylon and Southern India as the "hybrid cinchona" is really as fertile, and the seedlings as true to type, as statements and descriptions indicate, two questions have to be settled: is the tree actually a cross between *C. succirubra* and one of the varieties of *C. officinalis*, or is it merely a very large-leaved variety of *C. officinalis*, approaching *C. succirubra* in robustness of habit and size of foliage. If it is really a permanent hybrid, then we have a right to conclude that *C. succirubra* and *C. officinalis*, differing as they now do in habit and in foliage, are only "forms" or "races" of the same plant, identical in origin, but diversified in robustness, foliage, &c., by differences of position as regards soil, climate, &c., continued through a considerable period of time. If, on the other hand, *C. robusta*, with its smooth, unlichened, tall stem, rivalling or excelling *C. succirubra* as a tree and approaching it in size of leaves, is but a very marked variety of *C. officinalis*, then the two so-called *species*, *C. succirubra* and *C. officinalis*, must be regarded as closely allied forms, of a family in which *C. calisaya* also holds a place, including *C. Ledgeriana*, which, from the wonderful richness of its bark, has been erected into a new and separate "species." Botanically, no doubt, the flowers and fruits will still be regarded as the scientific tests of species, varieties, &c., but bark characteristics, by which alone the Australian settlers recognize the various "gums" or *Eucalypti*, are still more marked in the case of the cinchonas. For purposes of culture the test of bark analysis, indeed, stand pre-eminent. The question of hybridization entirely aside, the cinchonas and, especially, the most valuable of all, *C. Ledgeriana*, are so addicted to sporting, that the analysis of the bark of a parent tree, whence seeds, cuttings or grafts are to be taken, is all-important. It is very curious that Col. Beddome should have adduced the dimorphic character of the blossoms of cinchona as an objection to the idea of hybridization, seeing that Dr. Bidie had adduced that very characteristic as the reason why hybridization was inevitable, when the different species, if species they really are, came to be cultivated side by side, or in such close contiguity, that the pollen could easily be carried from tree to tree by the agency of butterflies and bees. Dr. Trimen, writing several years after Hooker and Thomson had penned the passage in the *Flora Indica* as to hybridism being rare in nature, has stated that the process is not unfrequent in certain groups of plants in their wild state, and the dimorphic blossoms of the cinchonas render them not only liable to the crossing process in their native forests, but give them a special tendency to intermixture when transferred to plantations and cultivated in large expanses. From this very tendency, a Ceylon planter, Mr. W. Forbes Laurie, who has closely studied the whole question, theoretically and practically, hopes for the best possible results, in the production and permanency of hybrids, specially suited for luxuriant and profitable growth in various zones of altitude and other climatal conditions. Already, it seems proved that *C. Robusta*, most probably a hybrid, *or cross* (?) between *C. succirubra* and *C. officinalis*,* will flourish where pure *C. officinalis* refuses to grow or *dies out*, and even where *C. succirubra* does not succeed or attains but a poor success. While awaiting the results of Mr. Moens' hybridizing experiments in Java, we trust our leading cinchona planters in Ceylon will not be idle, but will try experiments in crossing species and varieties, as well as in grafting. On the other hand, the tendency to hybridization being established—and he must be a bold man who now ventures to doubt this tendency in the cinchonas,—the necessity becomes obvious of precautions to protect the blossoms of superior Ledgers and other species or varieties of ascertained value from being tainted by intermixture of the pollen of inferior kinds. So difficult did Mr. Moens find this task in Java, that he got Government to consent to the eradication of the inferior kinds, while he took to propagating the better, by means of grafts placed on vigorous stocks of *C. succirubra*. Owners of plantations in Ceylon cannot take all the precautions which are possible to the Director of the Java Government Plantations; but much can be done by means of muslin bags, such as even our anti-hybridity friend, Mr. W. Smith, placed on his grand Ledgeriana trees, out of deference no doubt, to the mistaken ideas and prejudices of weak-kneed brethren, who are unable to resist the strong and cumulative evidence in favour of the tendency to hybridism or crossing amongst the cultivated cinchonas. The tendency admitted, the clear duty of cinchona planters is to avail themselves of it for the production of beneficial results, and to take all possible precautions against the process, where they know that it could only lead to deterioration of an existing superior type, such as *C. ledgeriana* undoubtedly is. Books on gardening afford full instructions regarding the artificial production of hybrid plants. The main principle is that the operator must cut

* A *cross*, on the assumption that *C. succirubra* and *C. officinalis*, however different in habit, are merely varieties of one species, like the Assam and China teas.

away the stamens of the flower of which the pistil is to be impregnated, and carefully prevent all access of pollen other than that which he brings to it. Darwin also laid stress on the principle that, in the case of dimorphic plants, the stigma of the one form should be fertilized by pollen taken from the stamens of corresponding height in the other form. Hybrids generally partake more of the nature of the male parent than of the female and, as regards permanency in hybrids, time alone can decide. The evidence as yet seems on the whole favourable to the permanency of what has been called *C. pubescens*, Howard; *C. lanosa*, Melvor; and finally *C. robusta*; one and the same plant whether its foliage is pubescent and *succirubra*-like, or glabrous and resembling *officinalis* in foliage, although far more robust in habit of stem. The differing results of constituents of barks obtained from individual trees certainly favour the idea of hybridity and there is the negative evidence obtained by Dr. Trimen from Kew, where specimens were compared, that, whatever else it may be, our robust tree is not *Pàtà de Galinazo*. Cases of graft hybridization are so rare and also so doubtful that, apart from Mr. Moens' distinct experience that a Ledger grafted on a succirubra retained its good qualities unaffected, we need have no fear that the inferior though vigorous stock plant will deteriorate the tree which it supports.

Before our article has passed from the hands of the printer, we receive the following information :—

RENEWED BARK OF "C. ROBUSTA" IN DIMBULA GIVING NEARLY 10 P. C. OF SULPHATE OF QUININE.

Such is the satisfactory report which reaches us with reference to trees growing on a well-known Lindula estate. Howard's analysis of the bark of the best tree is as follows :—

S. of quinine =	Quinine.	Cinchonidine.	Cinchonine.
9·78	7·3	1·47	0·35

Another tree gave 9·53 sulphate and so on down to 7·23 which was the minimum from the bark of seven selected trees. In one case we have an analysis :—

S. of quinine =	Quinine.	Cinchonidine.	Cinchonine.
9·15	6·86	1·27	0·67

This bark, we are told, was renewed under māna grass for 6 months and was uncovered for 3 months more —9 months in all. Had it been covered for the full 9 months, the proprietor thinks, the result would have been still better; but we are not so sure about that. It would be well to experiment after analysis, to settle a point of this kind. Meantime the proprietor of these fine trees may fairly be congratulated on possessing as valuable a collection as any of average Ledgers, considering the greater vigour and growth of bark usually made by *C. robusta*.

Cases like this go far to confirm belief in a great future for cinchona in Ceylon, by the appearance of hybrids or the development of varieties specially amenable to cultivation, specially rich in alkaloids and specially suitable for local circumstances of soil and climate. Encouraging intelligence, also, has just reached us, regarding the development of recuperative powers in plants long dormant and regarded as dead. Our correspondent, writing from an estate in Dimbula where tens of thousands of cinchonas had "died out" at various ages, states :—"The old cinchonas that have survived are flourishing and shewing no signs of canker; miserable plants that have stood still for five years (planted in 1877) are sending out new suckers—a hopeful sign."

MAURITIUS.

(From the Mauritius *Mercantile Record*, 16th May.)

The Weather and the Crop.—Since the departure of the last mail, there has been very little rain, but for the last few days we have had some rather heavy showers almost all over the island. However, on the whole, the weather has been warm and dry, and the last rains we had came just in time to prevent any harm being done to the plantations. Our prospects for the next crop continue to be most favourable.

Shipments of Sugar.—The following is a comparative statement of the sugars shipped of the crops of 1879-80, 1880-81, and 1881-82 from the first of August 1879-80-81 to the 14th May of each following year respectively. It will be be observed that we are behindhand in our shipments in respect to those of last year to the extent of 4,526 tons, and in respect to those of the previous one we are in advance to the extent of 21,574 tons. The total shipments during the last month have equalled 10,091.

	Crop 1879-80	Crop 1880-81	Crop 1881-82
	Tons of 1,000 kilogs		
United Kingdom	4,693	13,976	12,424
France ...	502	2,776	1,071
Australian Colonies	35,056	40,691	35,017
Bombay	27,496	38,626	28,656
Cape of Good Hope ...	5,809	5,347	8,369
Sundry Places ...	5,023	9,263	2,516
	78,579	110,679	106,153

Vanilla.—In Vanilla pods, no transaction has taken place since our last overland. The stock in first hands may be considered exhausted, and the shipments by the mail steamer leaving tomorrow may probably be the last for the crop 1881-82, which can be valued at 23,000 kilos. There may be about 500 kilos in second hands. The deficiency in the yield of green pods, caused by the heavy rains, is estimated at 30 o/o. Few are the planters who are willing to sell their green produce; yet sales have been made at R4 per kilo, all sorts included, and at from R5 to R5-40 per kilo for fine pods of 6 inches and more.

ESTATE PROPERTY IN MAURITIUS.

Sugar Estates.—Nothing persuades like success. Persons who were doubtful as to whether forming Sugar Estates Companies was the thing to be done to save our colony from estate-wreck can no longer hesitate in acknowledging the stubborn fact that Sugar Estates Companies will be the saving of the colony. The well-known success of Dr. Icery's Company, that of the Highlands Company, and now the confirmed success of the Northern Company, will prove to the most obstinate that Companies in the hands of first-rate men of business in the planting line, but above all under the direction of a thoroughly good manager, will always succeed. A profit of 28·17 per cent. for the year,

of which is 18 per cent. paid in a dividend, is a truth doubly proved that Sugar Estates Companies are the real thing.

A new Sugar Estate Company is established under the style *Compagnie sucrière de l'Union*. This Company has acquired the two sugar estates of Messrs. J. Constantin & Co. at Savanne: L'Union and Petit St. Aubin.

It is stated that the estate *Bar-le-duc* belonging to Messrs. Chastellier & Co. has been acquired by Messrs. Leclézio for a price of R400,000.

The estate *Henrietta* belonging to Messrs. Shand & Co. and *Réunion* to Mr. G. Robinson have been converted into a Company under the style of the *Vacoa Sugar Estates Company*, the capital fixed being RI,500,000, value of the 1st of April last.

It may be seen that Mr. Robinson as a thorough man of business has lost no time in setting himself to work; he is here for the last few days only on his return from Europe and he has already succeeded in starting the above large operation.

It is stated that a new Sugar Company for the working of the estates *Maison Blanche*, *Mon Rocher* and *Mon Goût* has just been formed under the style "The Pamplemousses Sugar Estates Company Limited." The capital will be R2,000,000 divided into ten thousand shares of R200 each. On that capital R450,000 of shares are now issued; the remainder will be affected to the purchase of new sugar estates, if necessary. The *Mon Désert* and *Helvetia* estates at Moka are in course of being formed into a Company.

THE ESTATE "PETITE RIVIERE NOIRE" (the portion known under the name of *Belle Vue* not included) has been sold by Messrs. Brémon & Co., for a sum of R70,000.—*Mauritius Gazette.*

TEA PLANTING IN ASSAM.

We regret that the second article from the *Pioneer*, which we publish today, should have been so long in following the first. We have already noticed the strange miscalculation about China tea imported into India. The actual quantity is nearer 3 millions of lb. than 300,000; although a considerable proportion of the tea so imported is again exported from India to independent states on its north-western borders. We believe also that, not only is Indian tea rapidly advancing in Britain, but that the import of China tea has considerably decreased. What tea drinkers in India and Ceylon, as well as Britain, have to learn is that good, pure Indian and Ceylon tea, though not relatively so cheap as the China stuff, is absolutely cheaper. The average of 200 lb of tea per acre of cultivated land is too low, because young tea and tea not in bearing are included. About 280 lb. per acre, or less than half the average originally anticipated, seems to be the return from mature bushes. It will be strange if we do not exceed this average, even on the estates of loftiest altitude in Ceylon. In any case it is evident that, if tea cultivation is to stand or fall on a question of labour supply, our enterprize has at least as good a chance of permanent success as that of our friends in Assam:—

THE ASSAM TEA GARDEN.

In reviewing the Assam Administration report for 1880-81, we mentioned that the area of land under tea cultivation in that Province was 153,657 acres in that year—being an increase of 3,047 acres on the previous year, notwithstanding a continued depression of the industry. The fact is that, in spite of a yearly increased difficulty in the matter of labour supply, the great tea industry of the lower provinces is steadily making its way, and is displaying a vitality which appears certain to insure it against the disasters that have befallen the, at one time, equally flourishing industries in indigo and silk. In Bengal, for instance, tea cultivation is now rapidly extending, and there were, in 1880, 38,805 acres of land under tea in that province, besides the quadruple area in Assam. In that year 50,276,883 lb. of India tea were brought into Calcutta, a very trifling quantity of which was from the Punjab and N. W. P. (323,629 lb.), and the rest from Bengal and Assam. Of this quantity 45,797,558 lb. were exported to foreign ports, which export was an increase of 21 per cent on that of the previous year. It is stated that:—"This increase was due in part to the enormous expansion of the demand from Australia in consequence of the Melbourne Exhibition; but a great increase was also observable in the exports of Indian tea to London, where the greater demand wafaccompanied by a decline in the importation so China tea."

Indian tea has thus not only successfully encountered China tea in India, where it has brought down the importations from China gradually, from 692,852 lb in 1876-77 to 343,495 lb in 1880-81, but also at home. In the latter case, it has not actually supplanted the China teas, for China maintains a fairly steady average of exports to the United Kingdom, but it has grown rapidly in favor by its side. Thirteen years ago the supply of China tea to England was fifteen times as great as that of Indian tea; it is now little more than three times as great. Moreover, a certain amount of China tea will also always come to this country. As remarked by the collector of customs in Calcutta in 1878:—"It is a fact beyond dispute that the inhabitants of India are developing a great taste for tea, and, as they cannot afford the expensively-manufactured Indian tea, it is for them that the inferior and cheap China tea is imported." China tea can be sold retail in Calcutta at 6 annas a pound, whereas the average value of Assam and Bengal teas is 11 annas to 12 annas a pound. It seems that India at present manufactures only black tea, and exclusively for the home and colonial market. It pays better to do so, and for that market the tea must be of best quality and consequently costly. It is stated in the Bengal administration report for 1878-79, that "the advices from home insist strongly upon the vital necessity of very careful manufacture in respect of quality, if Indian tea is to compete successfully with China tea in the London market." The fact is that India cannot hope to compete with China in cheap teas, owing to the immense advantage that China possesses in respect of labour. Indian tea must be comparatively expensive; therefore its only chance is to excel in quality, which depends on care in cultivation and manufacture.

In the early days of Assam tea it was estimated that in the fertile soil of that province 800 pounds to the acre would be a possible, and 600 pounds to the acre the average, outturn for a tea garden after the third year. This was for the luxuriant hybrid plant, which is that generally used in the plains. The Assam returns for 1880 show an average of 280lb. per acre, but the Bengal report says:—"The average yield of tea per acre calculated upon the entire cultivation is now believed to be rather over 200 pounds. This amount, though falling far short of the sanguine expectations of the first days of tea planting, is amply remunerative, and the prices obtained show that the average quality of Indian tea must be very good. It is unquestionable that the industry is now in a good and safe position. The cultivation has enormously extended, and the gardens are, as a general rule, well filled with plants, highly cultivated, and carefully managed."

Evidently then what Indian tea must stand or fall by is the supply of labour. There is any extent of land obtainable under the most favorable conditions of soil and climate, but this is in districts where unfortunately not only is the population scanty, but the very condition of soil, climate, and ample available area which favor tea also render the people averse to and independent of labour. Where this last is not the case, the other conditions are absent. In the Chittagong hill tracts, for instance, there is abundance of local labour except at the time of the rice harvest. Chota Nagpore again is the source whence most of the Assam labour has hitherto been supplied. But then "the soil and climate of the Lohardugga district (Chota Napore) are said not to be suitable for the successful cultivation of tea; but this drawback is partly made up for by the relative cheapness of land and labour," and the same applies to the Chittagong Hill Tracts. Thus Indian tea depends upon the facilities for importing labour to the districts where tea can be advantageously grown. To speak first of Assam, as being the principal tea growing district, we find that there was at the end of 1880-81 an imported labouring population of 187,300 souls in the tea gardens of Assam. Now, as this class of labour is only under contract for a fixed period (after which the coolies are free to take up lands and become lazy Assamese), this population has to be fed by constant immigration, to keep it up to its present strength, besides the increase required for extension of tea cultivation. But we find that the supply is steadily diminishing. The Assam report for 1880-81 gives a statement, showing that the coolies imported to that province for the last four years are as follows :—

1877	...	...	31,897
1878	...	...	43,061
1879	...	..	24,712
1880	...	...	15,913

The Bengal report for the same year says that the Bengal recruiting grounds are almost exhausted and "that managers of gardens must for the future look to upcountry labour to supply their requirements." It is there also stated that "Bengal has almost ceased to be a field for the supply of colonial immigrants," nevertheless no less than 12,185 coolies were found, not only for the British colonies of Mauritius, Demerara, Trinidad, Jamaica, and St. Lucia, but also for the French and Dutch colonies of Guadeloupe and Surinam. Now it would certainly seem as if the Provinces of India had the first claim, and that until this was satisfied coolie emigration beyond the sea should be discouraged.

But, until 1880, it was the coolie emigration to Assam that was discouraged. At last, on the 6th of April 1880, a London association memorialized the Government of India, praying that some measures might be taken to improve the position of the tea industry by removing the disabilities imposed by the Assam Labour Act passed in 1873. This has now been done by Act I of 1882, and the probable result will be a greatly increased importation of coolies into Assam from the N.-W. P., Oudh, and Behar, the provinces which have hitherto supplied the colonies. Darjiling and Julpigoree draw their labour from Nepaul, but it is obtained with difficulty by the latter, and those gardens, too, will soon have to recruit upcountry. Dacca, Chittagong, and Lahardugga can still depend upon the local supply. On the whole it may reasonably be supposed that the tea interest, with improved arrangements, should now be able, under the new Act, to obtain an adequate supply of labour without excessive trouble and cost. Some of the Calcutta firms interested in the supply of labour to the tea districts have adopted a system of establishing depôts and obtaining contractors' licenses for their own special agents, which appears likely to produce marked results on the character of recruiting operations. Hitherto, the gardens have either trusted to professional contractors supplying coolies for a consideration, or else have sent out garden sirdars to bring in recruits from their homes. The former system was in every way unsatisfactory. The latter had this disadvantage, that either more men had to be sent out than could well be spared to recruit each a few men, or else large sums had to be entrusted to men for whose zeal and honesty there could be no guarantee. Under the provisions of the new Act for enforcement of the labourer's contracts and prevention of desertion, and with the improved arrangements for transit and the preservation of health, the planter will now obtain the services of a much larger percentage than heretofore of the gangs that he imports at great expense, and the cost of the individual coolies therefore will be less. So long as labour can be imported at less than R100 per head and kept up at a less average rate than nine rupees per month per working hand, on gardens yielding 200 lb. of tea per acre of mature plant, so long, it is said, will tea planting be a remunerative business. It may be accepted that for some time to come the expenses will be kept far below these figures.

THE NORTHERN TERRITORY OF SOUTH AUSTRALIA FOR TROPICAL PRODUCTS.

(From the Special Reporter of the *Adelaide Observer*, May 13th, 1882.)

GOVERNMENT GARDENS: SUGAR, COFFEE, CINCHONA, TOBACCO, MAIZE, ARROWROOT, COTTON, INDIGO, PEANUTS, FRUIT, INDIARUBBER, GRASSES.

The Director of the Palmerston gardens is Mr. Holtze, and the reader ought to post himself up in the miracle which that gentleman and the soil he cultivates have jointly wrought. The garden is about four miles from Palmerston, verging on Fannie Bay, and it was established by the Government for "the express purpose of raising plants of commercial value and distributing them over the country." The institution was originally started upon the recommendation of Dr. Schomburgh, Director of the Adelaide Gardens, and of all the worthy botanist's excellent suggestions none has proved more practically valuable than this.

There was another garden once nearer Palmerston. The old enclosure is used as the police paddock now. Eight acres of it were cleared, and it subserved principally the highly important purpose of growing vegetables for the officials. Mr. Holtze succeeded its former director about four and a half years ago, and audaciously hinted that to cultivate cabbage hearts was not the greatest ambition of the true gardener, or the most important operation for the country. So he cut down the supplies, and put in various tropical trees and other plants, and then suggested that a fairer trial would be given to the average of the Northern Territory soil, if a different plantation were obtained. He was allowed to get another, and he selected the present garden—then thick jungle mostly, in the position indicated. He has been blamed for doing so; the land is indifferent, the blame-givers say. And he says so too, but significantly he pleads that his selection is the best for experiments, and that he is now able to say to intending planters:—"You see, gentlemen, I have grown canes so many feet high on this indifferent ground; on good land you ought to have 25 per cent. more of measureable success." And he has repeatedly urged that there should be another Government garden upcountry—at Yam Creek, for instance—where there is good soil. What one failed in might be the other's strong ground of success.

The area of the garden is thirty-two acres, and it was chosen at a time when crowds of Chinamen came in from the gold-fields, half-starving, to demand rations from the Government. They were engaged (as in a relief work) at 1s. a day to clear the selection, and they did—did it "most horribly," Mr. Holtze assured me. By the 1st of

November 1879, it was fenced ready for planting, and then trenched twenty inches deep. The plants from the old garden had to be conveyed to the new; and as a most rigid economy was enforced, Mr. Holtze, in the early morning and late night, before and after superintending the operations of the day, carted them himself, and got nothing more tangible than thanks for doing so. And now the reader knows the history of the place, and it is important that he should, to appreciate the sequel, as I describe it as I saw it two years and four months after its establishment. I ask him to bear particularly in mind the fact that only so short a time ago the land was thickly covered with jungle, and that the soil is merely second-rate.

To reach the gardens you branch off from the telegraph line on the road to Southport, and continue to ride for a mile through high grass and patches of thick jungle. The position of the place is picturesque in itself, and it commands a grand view of sea and seabeach, backed by distant, hazy, slightly rising land. The residence of the Director is built upon what are known as the "Northern Territory Government architectural lines," and the artistic effect is not wholly bad, whilst the comfort of the person residing in the erection is fairly promoted. There are huts for the Chinese gardeners, and there is a place in which a little of the produce can be stowed, but a seed-house and a few other structures are badly wanted. Mr. Holtze's salary is only £250 per annum, with quarters, and the amount voted for the gardens last year was, besides, but £500. This year it was £4,100.

Seventeen Chinamen are employed. Two of them get 25s a week each; two more, 20s; and the rest only 15s, without rations in each case. Mr. Holtze gives them an excellent character. He prefers them to Europeans for garden-work; and he has had both working and ought to be capable of forming a judgment. He remembers, of course, that men slaving nine hours a day, wet or shine, for 15s a week, cannot be expected to be over-energetic, unless they are pretty thoroughly overseered. Granted that reservation, he says that, whilst they certainly are "slow," they work well and get through more than any Europeans he has had ever got through whilst they were with him.

I got this information from Mr. Holtze ere we had gone into the gardens. When we had done that, I had an opportunity of seeing the men at work, and they put in a great many strokes to the minute whilst we were looking on. When their master's back is towards them, however, they are not, I have since found, too eager to injure themselves by over-exertion, and you really cannot expect them to be with such pay, when they know Europeans would get £6 at least.

The examination of the gardens was the greatest surprize I have had in the Territory. A wilderness a little more than two years ago is now an umbrageous paradise. Acclimatized trees shoot aloft and tower above the native ones outside full twenty times their age; they bear most luscious fruit, in quantity unstinted. Creepers indigenous to a foreign soil planted here have run at once over the place and now grow everywhere in wild profusion: and many herbs, well known and grown down South, after a year of cultivation here attain an immense size and spread weed-like through the adjacent land. Each area of the garden is only another greater wonder than the last, and, if I but cared to wax rhapsodical I certainly could not be justly charged with wanting warrant for it.

But I do not choose to go into rhapsody, and so I will condescend to the practical, with some little detail as to the most prominent experiments and their results.

First, as to sugarcanes, of which there are eight varieties, spreading over sixteen acres, in the gardens. Mr. Holtze affirms that it is bad this year, because he would not cut the last year's crop till the end of December, having orders to have some sent to Delissaville for crushing—the crushing which proved, through certain blunders, so disastrous. Through this the canes lost six weeks' growth, and Mr. Holtze fee'ls very much annoyed at the result. Yet everybody outside agrees that the canes are grand successes, though they are a trifle less satisfactory in appearance than were those of last year. When I visited the garden some of them had made six or seven feet of "cane," and that is almost twice as much as any else I have seen here have done. Of course it should be remembered that these grew from the rattoons. Speaking of the growth of sugarcane in the Territory, Mr. Holtze says—and it will be of interest to give the result of his experiments—that it should be in by the commencement of October. DeLissa and others planted in December, and he predicts that their crops will not be one-half so good as they might have been. In sugar-cultivation generally he thinks it would be better for the first year or two to plant only cane-heads, and take the old roots up, and also to observe some rotation of crops, alternating the cane with something else. An idea of the important work the gardens have done for the promotion of the sugar-growing industry of the country may be gained from the fact that 140 tons of cane have have gone this season alone from them to the various private plantations and a little to Chinese gardeners. The latter further took, including a few to Europeans, 8,000 banana plants and 13,000 pineapple trees. This year the numbers already are respectively 2,000 and 5,000. All these are given away. The cane is even cut at the expense of the Government and thus the garden gives no return whatever except a very untangible one in the shape of fruits for Government officers and fodder for their horses. Mr. Holtze suggests,—and I believe the planters do not object to the suggestion—that a small charge should be levied for the care at least—say a couple of pounds a ton. Then the persons getting it would enjoy a great advantage, which they would not have, had they to ship the plants from Queensland, and in the latter case they would not get them in nearly so fresh a state. Besides the planters, many diggers and settlers upcountry are getting seeds from the gardens. Mr. Holtze gives the carters those of the foreign grasses he has proved to be best adapted to the soil, and gets them to scatter them all over the country in the neighbourhood of their camps. The pineapples and bananas thrive even better than the sugar cane. I tasted all three—I have tasted so many tropical fruits and vegetables this trip that I believe I could name them each by flavour ten years hence—and I found them all that could be desired. The sugarcane particularly, with its soft, sweet, soppy juice, keenly appeals to one's susceptibilities. It reminds him of the days when he, like the pulpy cane, was in his infancy.

Going through the sugar acreage one naturally wants to know where the white ants have been that the crop should be so healthy. I closely examined each plot, and only in a few cases were there any signs of the ants. Mr. Holtze has a wholesale contempt for them; and, when you ask him whether he thinks the little pests will be a considerable factor in the planters' losses, you see an indignant man. He opposes to the ants arsenic and potash, and the common so-called remedy of carbolic acid he impeaches with Teutonic warmth as "nonsense." "It is all very well for the first time, so long as the smell is there," he says, "but when it leaves the ants are coolly walking over the powder and taking it to whitewash their cells with. Now I dilute my arsenic and potash in hot water, and take sugar and flour and make a paste. Whenever I see white ants I make a hole and fill it with a spoonful of the mixture. I never have the least trouble with them. Arsenic," he points out, "is a never-ending poison. The father ant takes it and dies. His sons affectionately eat him and they die; their mother and sisters devour them, and all give up the ghost, and so destruction goes on for ever." If his be the true solution of the ant difficulty, it certainly is a very inexpensive one. Four years ago in the old gardens he bought a half cwt. of arsenic: half of that he has still. With what is gone he has conquered the ants.

Maize is the next principal crop in the garden, and it is looking as well as it can look anywhere, notwithstanding that it is the third crop in a year. Rice simply flourishes, strengthening the evidence I have had throughout that the Northern Territory will be a great rice-growing country. Only the hill kinds are tried in the gardens, because the ground is too high for the swamp varieties.

Cinchona has not been successful. The seeds did not even come up, and Mr. Holtze maintains that the climate is too hot for it:—"It is all very well to say that it thrives in Ceylon, but there are high mountains there. We haven't got those mountains." On Messrs. Poett and Mackinnon's plantation at Rumjungle, however, the seeds have germinated, and the little plants look healthy enough. But then the climate is

different and the soil is better. Dr. Schomburgh wrote years ago that cinchona should be successful there."

Coffee does not do well in the gardens. The prime cause is said to be the fact of its being planted so near the sea. The Arabica is not unhealthy-looking above ground, but it has no root. The Liberian looks sturdy, and Mr. Holtze is confident that it will succeed on the plantations. It needs great care and attention, however. Tea and several spices have failed. They have been tried fairly, and, though they make plenty of leaves, they have no root. Cocoa is moderately successful.

Tobacco has not been as satisfactory as it was believed it would be. The plants I saw were very young, and I could not judge of them, but my conductor said that he has grown leaves 27 inches long by 18 inches wide, and that, I should think, is satisfactory enough. But he fears otherwise—says the soil is not fit for tobacco. He suggests, however, that in the more favoured parts of the country 100 acres in a crop of tobacco alternating with rice every year would pay well.

One of the best things in the gardens is the Arrowroot, which actually overruns the place, growing in grand perfection weedlike. Mr. Holtze ground some of the roots with a nutmeg-grater, and carried a few pounds of the powder he got in this way to the storekeepers for an opinion as to its quality, without letting them know whence he got it. They told him it was superior to any they had in stock. He took the roots from a fair average area of the crop, so that he might make a calculation as to the probable yield if all were ground. He is satisfied, as a result of that calculation, that even the indifferently good soil in the gardens will yield at least 25 cwt. of the finest arrowroot per acre.

Though Cotton grows well, there is a question in my guide's mind as to whether it will pay while labour is so dear. He submits, however, a proposition which he conceives to be perfectly reasonable: that, though he would not advise any one under present conditions to start cotton-growing, yet, if the Government want a cotton plantation, and will give him the use of 10,000 acres of land, he will try for five years to establish one. If he be successful, then he will pay 7s 6d an acre; if not he will yield possession again to the Government. There are two sides to that proposal, however.

Among the grand successes in the garden is the cultivation of Indigo, information concerning which Major Fergusson received special instructions to obtain whilst he was visiting India. The plant has run from the gardens into the surrounding scrub and jungle, and you see the bright, blue flower and the pretty dappered leaves on all hands. It overruns the gardens too, and indeed it seems as though it never enjoyed its most congenial climatic influences till it got them here. In India its average height if one may believe the books, is not much more than two feet, here it is over five feet. "There'll be many fortunes made in Northern Territory in indigo," said my conductor, and I quite believe him. Those who have travelled lately through India say that the necessities of its immense and ever-increasing population in the shape of food supply are always becoming greater and more pressing, and as a consequence the cultivators of indigo have to make food production their prime business. So the acreage under the dye-plant is gradually decreasing, though, as a matter of course, the demand is in an inverse ratio. Hence, and for other reasons, it is safe to back the prediction given below,

I should have mentioned, when I wrote of Tobacco, that Mr. Holtze gave me some cigars which he had made roughly—for he confesses to not understanding the work—from leaves grown in the gardens. Although new, they smoked as well as the best Manilla, and they were milder—or at least they seemed to be—smoked as a variation af the exercises of sugarcane and maize and peanut and chili chewing—for I had scrupulously to sample everything that grew, and I felt like an Indian salad dish. And, by the way, there appertains to these cigars a little joke. The Government Resident had a box of them, and he valiantly championed their virtues whilst, as usual, men who ought to be the first to support "local industries" decried them. They were colonial; that was enough to damn them. He determined to given them fair test. Shortly afterwards he gave a whist party, and placed these cigars before the company without remark. Unasked-for came exclamatious of surprize at and comments upon their excellence. And then the murder was out! I can understand the commendations, for I have paid sixpence for a much worse cigar in the southern capitals. The first energetic and competent tobacco-planter and curer in the Northern Territory will doubtless make a fortune rapidly.

When I tell the reader that there are nearly a thousand kinds of plants in the gardens, he will thank me not to detail all the experiments. And so I pass over a great many, which meant months of careful watching and study in consummation, and most of which were successful, notwithstanding that there is not the slightest forcing to gain success. Not so much as a shovelful of manure has been used in the whole garden, and not a single plant has been watered except by dew or rain; for the Director contends that, if a thing will not grow without watering, then it is no good for the Northern Territory; and to the end that the conditions necessary to general success may be tabulated as far as possible, Mr. Holtze studiously takes every day thermometrical readings, and by a gauge registers the rainfall. This latter operation in a country where the downpours are so very partial is of great importance. It is more satisfactory still to know that the gauges were more plentifully distributed, for it would give the planters precise information. The new ones can, having registered the rainfall whilst they were clearing, come to the gardener and say: "My register is so-and-so; temperature so many degrees. Here's a sample of my soil. Shall it be sugar-cane or cotton, indigo or maize?" Easy as most theories, you observe.

But, continuing my summary, I may add that, much to my astonishment, I was introduced to the grand old Scotch kale, healthy and hale as its kin in the old country; to its warm friends pepper and cloves, and capsicums and cinnamon, all either flourishing or looking like to flourish; to healthy lycheenuts, mangoes and bread-fruit, guava, jackfruit, yams, melons, beans, and sweet potatoes.

Peanuts particularly thrive. Last year one-fifteenth of an acre gave 4 cwt. Eight hundred pounds to the acre is considered a good crop in California.

The Manilla Almond looks better here than on its native heath, and English apples, grapes, and peaches grow, but the first and last, I thought, seemed pining. Some Spanish and navel orange-trees were in fair health, but the ironstone-sprinkled ground is not the fittest for their tribe to live on. The mandarin oranges, however, as I proved by sight and taste, had not depreciated one whit by transplantation, nor had the limes, lemons, citrons, and pomegranates, nor the many-formed hibiscus, nor Cape gooseberries; chilis, custard apples, carob-beans, figs, almonds, plantains, earthnuts, sorghum, sesamoil, cassava, castor oil, sweet sob and sour sob, rhea or Chinese grass plant, and others whose names are semilegion. The coconut was tried, but not successfully. The nuts were planted on the beach, and one can hardly affirm that the experiment was a fair one.

To Baron von Mueller the Director expressed his obligations generally, and particularly for recommending trial of the Indiarubber tree. Four months before I visited the gardens its seeds were sown, and I was introduced to a flourishing tree eight feet in height. The expressed and congealed juice of this indiarubber plant will unquestionably be one of the important minor articles of export from the Territory. So will palm oil from its tree, which grows luxuriantly

A big shade-bamboo nursery in the centre of the gardens is filled with many rare and choice young plants. Here, as with respect to some at least in the open, scores of acclimatized and native grasses grow The best to succeed is the common Phillips's. The English lawn grass grows well under shade, but does not seem to stand the heat, and yet I have seen a capital lawn in Palmerston; where exposed, not artificially watered, its growth is satisfactory enough. The Alizana Indica thrives in the gardens; but Mr. Holtze's opinion is that the native grasses are not as good as the imported are in their own home, and better than they will be here. He has been experimenting with the tall rank kinds I have described in my notes on the down-country travel, and he discovered that by cutting them down frequently he got at last a thick, soft, fast-spreading, somewhat dwarfed buffalo grass, which surpassed the best couch for lawn and feeding purposes.

English lucerne grows well, and the reana, a luxuriant fodder-plant about fifteen feet high, springs up with surprizing rapidity. Jute has failed this season, owing to the unusually dry weather. The plants got sickly, and were attacked by a maggot like a gentle. The so-called broom-

corn, from which American brooms are made, grows splendidly. I saw a thick plot, averaging fifteen feet in height. All the Chinese oil-plants grow well. The "teal" has spread—self-sown after the first year—all over the garden. Its juice is a capital lubricating oil; 1,200,000 acres are planted with "teal" every year in India. The six odd figures would give us a grand export for the Territory. Many different sorts of millets yield a heavy crop, and a row of mulberries are strong and healthy. The Director is importing some silkworms to live in them, and thus he will nurture two industries in one. Of Chinese bamboo-silk I have with me some good samples which I combed out from various thriving trees eight feet high. There is no doubt as to the success of this plant, and, as the fibre is valuable in cloth manufacture, its cultivation would be an important subsidiary aid to the planter. An African fibre-plant is equally successful, and so is the Indian physic-nut, used medicinally. The papoya-papa-papaw-papia (for it has as many names as a Chinese sharper has tricks) is amongst the most healthy fruit-producers. It is a peculiar plant. There are male and female. The male tree only flowers; the others add the fruit. The males are the hardier, and on one plantation I visited there were no females, and hence there was no fruit. The males have to be inoculated by bees, it is said, and, where the bees neglect their duty, the tree is of no account except for ornament. The fruit itself is to some tastes delicious, though others don't like it. It is a cross between rockmellon, a banana, and a pineapple.

And now, having served my purpose, I think I may finally close my notes on this important subject. I cannot do better than confirm from my own observation during several visits what the gardener says—that "everything imported that grows in this country thrives." At first plants which are most notably successful now pined. The proper season for planting them was not found till experiments had been made. When it was discovered, there was no further trouble, and it is only a reasonable surmise that the same thing will repeat itself till, when the purely experimental work shall have been completed, we shall have thousands of vigorous acclimatized plants where now there are only hundreds. That the trial may be perfect Mr. Holtze is getting from all quarters every variety of each plant, and of course he gives exchanges. The garden, be it understood, is not a place for floral beauties or the kickshaws of cultivation. Its strong point is its strictly commercial character, and in that point it is simply Herculean.

THE COFFEE LEAF FUNGUS AND STORCK'S CARBOLIC ACID TREATMENT IN CEYLON.

An Uva correspondent asks, in view of recent discouraging reports, how not a few Ceylon proprietors persist in experiments with carbolic acid as a preventative of *hemileia vastatrix* on their coffee. Among the rest he specifies the Hunasgiriya, Uva, Spring Valley and Ceylon Companies as being importers of considerable quantities of carbolic acid. We are glad to learn about this importation, for a careful experimental trial after Storck's plan is still required to decide the question of its value in Ceylon, and since we last referred to the subject we have heard from more than one quarter of encouraging results obtained from preliminary experiments. Contrary to the opinion of Dr. Trimen and Mr. Wall that carbolic acid is not volatile, we have cumulative evidence from gentlemen experimenting for themselves, of the readiness with which it evaporates, and of the powerful effect of the acid when placed in the vicinity of fungi, although not in contact. One gentleman suggests that sceptics should suspend a pair of boots over a tin with a small quantity of dilute carbolic acid, so that the fumes may pass round the boots (*à la* the coffee tree), and contrast the result in freedom from mouldiness with another pair similarly hung in a different place! The following has been handed to us as the results of experiments made :—

Four days exposed to the action of the atmosphere in a room in an open vessel.

Sulphuric acid increased in bulk and in weight	290 grains
Muriatic acid increased in bulk and in weight	98 ,,
Carbolic acid decreased in bulk and in weight	15 ,,
Water decreased in bulk and in weight	60 ,,
Arrack decreased in bulk and in weight	395 ,,

From the above it will be seen that carbolic acid evaporates very slowly, but it may be none the less effectual in the destruction of fungi. In all accounts of the substance, including the article in the new edition of the "Encyclopædia Britannica," it is separated from the alcohols, and, apart from its great value in the production of aniline dyes, its antiseptic properties are chiefly dwelt on. We suppose that the property which enables it to arrest decay and destroy odour in putrifying meat and other substances, is that which renders it a fungicide, fungi being the great agents of decay? or at any rate always present as products of decay. But we should like to hear experts like Messrs. Wall and Dixon on the whole question of carbolic acid and its possession or non-possession of the power of destroying fungi by its vapour.

A later memorandum is as follows :—

14th June 1882.

Carbolic acid in an open tin vessel exposed to all weathers lost 1 ounce and 70 grains in weight in six days. The net weight of carbolic acid exposed on 8th June, was 1 lb., 2 oz. and 30 grs.; therefore, about one-sixteenth part disappeared in six days, and so it would have evaporated entirely in 96 days. In another case, a planter who has been using carbolic acid in the way prescribed by Mr. Storck in a nursery has been greatly surprized at the rapidity with which it has acted on the fungus on the coffee leaves. In other cases, from one to five, and even thirty acres are being experimented on. On Warleigh estate, Dikoya, a combination of Messrs. Schrottky's and Storck's methods has been tried with, it is understood, good effect. A proprietor who takes a great interest in carbolic acid experiments writes :—

If you can rely upon the *bona fides* of your Fiji correspondent, "A. J. S.," who tells you, in his last communication, that he thinks so well of the cure that he is putting in hand 20 *acres* at once, we ought also to be stirring in Ceylon. I have read and reread Storck's paper many times and the plan seems to be well worthy of a trial throughout Ceylon. Two months ago, I commenced an acre. My neighbour has now commenced five acres, and many are trying it. I think the liquid has advantages over the dry treatment, but the carriage of water may, on some estates, become a not inconsiderable item. If you hear anything of its success elsewhere, I hope you will let your readers know of it. About a month ago, I saw its effects on a nursery, and it seemed to be acting then, after a week only, like a charm, but until the 12 months are ended we must not say too much. The article (Mr. Storck's) in the *Tropical Agriculturist* is rather long. We want a SHORT SUMMARY in *large print* to be pasted on boards and hung up in the superintendent's office walls, *i.e.*, if the experiments now being made prove

successful. Perhaps "A. J. S." can give us Mr. Storck's promised new idea, *re* the saving, as he says it would probably save considerable trouble and expense."

We shall be much interested in hearing of the result of the various experiments, and, if our correspondent "boils down" Mr. Storck's account of his treatment, so as to give the pith in a small space for the guidance of superintendents, we shall be glad to print placards for him, and give the summary prominence in our columns.

We learn that experiments made with carbolic acid among coffee at the Straits afford good promise of success.

WHAT "CINCHONA" IS DOING FOR THE CEYLON COFFEE PLANTER.

We lately gave several instances of the welcome aid obtained by much-tried coffee planters from the harvesting of cinchona bark; but we think no case then mentioned was, on the whole, so satisfactory as the one now brought to our notice. The owner of 11,000 succirubra trees,—four, five and six years old—growing among coffee about 4,000 feet above sea-level, began "shaving" in March and has since continued the operation at intervals. His first return was 2,000 lb. dry bark, or rather shavings, which have sold for £250 in London; he has since got in about 7,000 lb., for which he is offered as much as ten thousand rupees locally, but which, he thinks, will sell even better if shipped. Altogether his 11,000 trees, without cutting or injuring one of them, will, with twig and branch bark, as well as shavings, bring him in fully R14,000 this year, with the good prospect of a still better harvest next season (provided, of course, the French savant's "substitute for quinine" does not come to the front); and all this, be it remembered, from shavings of the comparatively despised red bark.

PLANTING PROSPECTS IN JOHORE.

To the Editor of the [Straits] "*Daily Times.*"

SIR,—No one who has seen much of Johore can read the letter taken from the *Ceylon Observer* headed "A Devil's Advocate about Johore" without thinking the writer had an object in sending to that paper such a spiteful, and I think, unfair account of one of its districts. The anonymous writer, to give his letter some weight with planters, begins by mentioning the opinion of Mr. Dobree and other planters who have visited Pulai, as being most unfavorable to that district. Mr. Dobree, however, said nothing in his report as to the soil being "sand mixed with sour clay."

I have just returned from a visit to the estates which have been opened at Batu Pahat, and, whilst there, I examined the soil in many places to a depth of 3 feet. I can safely say I found nothing answering the description, "sand mixed with sour clay." I would call it a light, sandy soil. It is a free soil, and all the low and sheltered parts will, I have no doubt whatever, grow cocoa with very satisfactory results. The cocoa and Liberian coffee I saw growing looked very promising. I counted 37 pods on a 2-year old cocoa tree, from which the superintendent had but lately picked 10 ripe pods. The tree was, in addition, covered with blossom. All the trees I saw were perfectly healthy and as fine as any I have seen in Ceylon of their age.

Cocoa, as every planter knows, is a tender plant when young, and the *Ceylon Observer* has more than once mentioned cases where there had been 60% to 70% of failures in the first year's planting. Now, although I do not mention Batu Pahat as having the best soil in Johore, I saw quite 60% of the cocoa looking as well as could be desired.

Liberian coffee could not well grow and crop better than it has done up to the present in Johore, and nobody can deny that it at least is a success in the country. I do not say anything of coffee Arabica, as, perhaps, through Ceylon prejudice, I do not believe in it at low elevations. I think, however, that everything that can be done is being done, in the way of planting shade trees, to make it a success.

In the way of labor, the average cost per man per diem is only 24 cents. Communication with Singapore is, as you know, by water. I believe H. H. the Maharajah's steamer runs once and often twice a month, and the Maharajah is good enough to hold it, free of cost, at the disposal of the superintendent or any visitors wishing to make a special trip. Fresh beef and mutton can be had only when the steamer goes up, but fish, fowls and vegetables can at all times be procured in abundance. There is, in addition, at Batu Pahat a well-stocked store, which can supply planters with all kinds of tinned meat, &c. Water communication goes to within a quarter of a mile of the nearest, and to within about 3 miles of the furthest, point of the range.

When sickness has nearly disappeared and the cost of labor has been reduced 20 per cent; when the difficulties of pioneering have almost been overcome by Mr. Watson after a trying struggle; surely, it is not the time to put faith in a letter written anonymously by a man who presumably left the country disappointed, and having a grudge against his employer. It does not require a planter of great experience to see that the luxurious growth and heavy produce of the Durian, jack and other fruit trees, that the magnificent pepper and gambier plantations, are not the outcome of a soil consisting of "sand mixed with sour clay."—Yours faithfully, W. W. BAILEY.

Singapore, 1st June 1882.

PENANG PLANTING NEWS.

(From the *Straits Times.*)

The *Penang Gazette* of the 29th May gives the following account of a deputation of planters who had an interview with H. E. the Governor in Penang on the 25th May:—

PLANTERS' DEPUTATION TO H. E. THE GOVERNOR.

An important deputation representing planting interests waited on His Excellency the Governor on Thursday last regarding the immigration question. The Hon. G. M. Sandilands, M. L. C., introduced the deputation.

Mr. Morrison, who acted as spokesman, said that an almost total cessation of Indian immigration had been occasioned by the illtreatment of coolies in the Indian Government depôts, as in them the coolies were allowed no liberty; they were herded together, both men and women, and were not even allowed to cook separately. He suggested that, either the planters' agents should be allowed to keep depôts under Government supervision, or that planters or their agents should be allowed free access to Government depôts.

Mr. Roberts assured the Governor that most stringent orders exist to prevent access to the depôts; he spoke from experience.

Mr. Morrison went on to say that immigrants were laxly looked after, and being dissatisfied with their treatment abscond before embarkation. On one occasion, out of 179 who entered the depôt 97 only embarked; the rest absconded.

Mr. Roberts corroborated this from personal inspection of the office books.

The Governor said he heard these statements with surprize. Mr. McGregor, the Protector of Indian immigration, had been sent to India with orders strictly to enquire into the arrangements there in every detail. He was expected to return very shortly, and, if he corroborated these statements, as further explanations were required, he would at once bring the matter forward, and make representations to the Indian Government. Mr. Morrison next brought under consideration the enforcement of the provisions of the law in regard to "cutting" a cooly's pay for short time of work.

The Governor replied that he was not above the law, and that, if the planters wished a change in the law, they must draw up a petition which he would carefully consider; but that they must be aware that there were strong reasons why any "cutting" of wages must be carefully guarded against. Mr. de Mornay then pointed out that, when a cooly wanted a day's leave now, it could not be given him, as there was no power, without troublesome reference, to deduct the day's pay.

Mr. Morrison requested that the new Indian Immigration Act might be pressed forward into law. The Governor said that it was only delayed because the Indian Government had lately pointed out that, according to their law, passage money, and he believed advances also, could not be recovered from immigrants. H. E. said that he had requested that their law might be altered in that respect, as otherwise immigration (other than free immigration) must stop. The gentlemen of the deputation expressed a general assent to this view.

Mr. Morrison called His Excellency's attention to Mr. McGregor's report as misleading in respect to his quoting the profits of Batu Kawan estate as representative of the financial condition of estates in the province generally. He said that, on those he (Mr. Morrison) represented, a capital of £154,000 only yielded a 4 per cent return. His Company could not afford to give increased wages; 16 cents would hardly cover the daily cost of a cooly; other gentlemen remarked that it was nearer 20.

Some conversation here ensued on the Governor remarking that it was unfortunate that higher wages than those now current could not be given in the colony. It was constantly found that men of one race broke their agreement, and left those who had brought them out, to seek higher wages elsewhere, and it could not be expected that a cooly should take a higher view of morality. Labour would like water find its level—it would always flow to higher wages; he did not think that any Government effort could prevent desertion so long as the rate of wages in Province Wellesley was less than in Perak. The Government had in the face of some opposition passed a measure to facilitate the capture of deserters, and Indian immigration to Perak was being pushed forward as rapidly as the necessity for preliminary arrangements would permit, and this would doubtless tend to equalize rates and diminish the temptation to absconders. In regard to offenders, the introduction of the treadmill into the gaols, which was decided on, would enable the authorities to see that punishment was sufficiently deterrent, which is admitted not to have been the case hitherto.

Mr. Morrision lastly brought forward the question of Chinese contracts.

The Governor produced the agreement which, after he himself had, as he believed, come to an understanding with the planters, was drawn up by Mr. Pickering, the Protector of Chinese acting under His Excellency's authority in connection with them. The Governor agreed on principle in favour of periodical rest being allowed to labourers, whether Chinese or others. His views on that point were in no ways altered by the statement that the coolies had not complained in this case; the indulgence was only asked for men who were unwell or needed rest. Indians, well or ill, were allowed 52 days (Sundays) in the year, and were paid for those days of rest, and had not to work them out. Afterwards Government only asked for 30 days for Chinese, who could plead ill-health, and did not ask that wages should be paid to them for those days. The Governor thought this was a very small concession to ask the employers to make. Mr. Morrison said that the planters would be content if 15 out of the 30 days were worked out afterwards. He also pointed out that the printed form differed from the written agreement now produced by the Governor as assented to by Mr. Pickering with His Excellency's authority.

The Governor replied that he would see Mr. Pickering on his arrival here, and draw his attention to this statement which bore upon a point of legal interpretation.

The deputation expressed their thanks to His Excellency for the time and attention he had devoted to them and withdrew.

NEW PRODUCTS IN CEYLON.

LOWCOUNTRY REPORT:

LIBERIAN COFFEE—COCOA—PEPPER VINES—VANILLA—CARDAMOMS.

NEAR HENARATGODA, 12th June 1882.

Excepting the five days that followed the 17th, when it did little but rain, May was a series of alternations of sun and shower.

The coffee has continued to grow, but hardly so rapidly as a few months ago. The oldest plants are ripening a little crop, and the last year's planting is beginning to branch. I planted all the plants that were sufficiently forward under what I considered very favourable circumstances, but within a few days a new enemy appeared on the ground. The new clearing had become fearfully dirty with the fresh crop of batal and other jungle products. This condition of the land seems to have suited the views of a species of moth for reproductive purposes, and the result was an immense army of caterpillars, that, finding the coffee leaves, among other things, to their taste, has reduced some thousands of thriving plants to mere skeletons, showing nothing but the stem and the midribs of the leaves. This is an unlucky chance, and, as it is altogether a new experience to me, I could not provide for it beforehand. I am now rooting and weeding the planted land to the quickest of my possibility, but I think the enemy has now nearly done his worst. The crows and minas had a week's feasting. That the plants will be thrown back and checked in their growth there can be no doubt, but, as the roots are sound, and the summit bud untouched, I have great hopes that nothing very serious will ensue, beyond a little retardation in the growth. All the injured plants, however, that do not make an immediate start after the weeding and rooting I will discard, and replace at my earliest convenience; for a Liberian coffee plant that has encountered a serious check will (however promising it may be for a time,) play its cultivator a dog's trick in the end. The *hemileia vastatrix* invariably feasts on a plant that has been checked in its growth, or has had its constitution weakened by any cause whatever. I have given the best that is in me to the observation of this matter, with the result that a Liberian coffee plant that has once encountered a serious check from any cause is almost certain to become the victim of *hemileia vastatrix* before it ripens a fruit.

I do not see that the fungus has extended to many fresh plants during the month, and those that have it chronic are neither better nor worse. There is, however, much difference in its effect on the different castes. There are certain varieties, every plant of which takes the pest early on every leaf and drops them regularly. Some get covered with pinspots, without seeming to catch much harm; the leaves do not fall, the plants flower freely and ripen their crop, as if nothing were the matter. A third class get a few pinspots, which never get beyond a few, and seem to have no effect of any kind: and a few of the noblest castes repel it entirely, if I may judge from their standing for years in the midst of trees covered with the fungus without contracting a spot.

It seems as if it would take years, added to the years of battle already past, to thoroughly establish cocoa here. On some spots defeat has been acknowledged, and the attempt may yet be abandoned on others, but I am gradually getting the trees out of danger from the enemies of their early youth. My largest tree, now nearly three years old, has been flowering for more than twelve months, but only once, about six months ago, did it attempt to form a few pods, which it dropped before they took form. I have, however, noticed, within the last two days, a better promise on less promising trees, so far as sizegoes.*

I carried out my idea of planting pepper vines, to run on the rocks, but few or none of them have struck, so I must try again.

The rupee's worth of vanilla cuttings I put down, six weeks ago, are getting on, and I would put down more, if I did not grudge a cent an inch for a plant that grows so freely.

I know not on what principle Dr. Trimen regulates his tariff of prices for plants. If it were the commercial principle, the prices would come and go, as supply failed to hit the exact balance of demand; if it were the principle of encouraging experimental cultivation, prices would be according to the rarity of the plant, or the difficulty of producing it. The prices of plants rare and precious may be fairly fixed, by any one having a monopoly, at the very highest that will secure customers; they have a right to make hay while the sun shines, but it is not business-like to go on charging, or offering for sale rather, at 25c. what outside producers offer at 5c., and surely the Government Gardens can find little custom for plants that have become weeds at many centres, and may be had in any quantity for the trouble of taking away—a rupee for a cooly load of cassava sticks, for instance, when its cultivators are only too thankful to those who will take them. As for vanilla cuttings (that led me into this digression), were there any market for them, which there is not, a fortune might be made out of a few hundred plants, by selling cuttings at one cent, instead of eight-and-a-half.

I have now about 300 cardamom plants ready for the field. I think I now know enough of the habits of this plant in infancy to make a better job of the next lot of seed I get.

We have had the true old form of monsoon weather since the 6th instant, and it still continues.

I am feeling the disadvantage of a public road through the property. Above fifty plants have been stolen out of the field after planting.

CULTIVATION OF CINCHONA IN THE UNITED STATES.

Hon. S. J. Randall presented the following in the House of Representatives a few days ago, and it was unanimously adopted:—

Resolved:—That the Commissioner of Agriculture be requested to inform this House whether any portion of the United States is adapted to the growth of cinchona.

Mr. Randall said: The subject is an important one, and I desire to call to it the attention of those who are interested in the growth of this tree in the United States. I have been more directly moved to submit the resolution by a letter, which I hold in my hand, from Professor Alfred L. Kennedy, of the Polytechnic College, Philadelphia." The letter is as follows:—

"Polytechnic College, Philadelphia, April 20th, 1882.

"My Dear Sir,—You are doubtless fully aware that the plantations of cinchona or Peruvian bark, from which the world derives its supply of *quinia*, are in jeopardy, and that Holland and England have, with a wise forecast, already provided against probable contingencies, by establishing in their Asiatic possessions plantations of the tree. It is so evidently the duty of our country to imitate this example, that I beg to suggest the passage by Congress of a resolution requesting the Secretary of the Interior to institute full and careful inquiry, and report to Congress whether any part of the public domain is adapted to the growth of the cinchona, with the view of having that portion reserved from sale until Congress take action on the report.

"The tree grows well up in the slopes of the Andes, in a rare and temperate atmosphere. Its cultivation in Asia has already afforded a bark yielding a higher percentage of the active principle than the bark imported from Peru. There should be no opposition to a resolution of this kind, and, although you are, I know, very much occupied, I trust that you will find time to prepare and present it at an early day.

Very truly your friend, ALFRED L. KENNEDY."

—*Oil and Drug News.*

[We do not believe that cinchona, any more than tea, can be cultivated profitably within the United States.—ED.]

COFFEE AND TEA LEAF-DISEASE.

Our attention has been specially called from Calcutta, to the following article on "Leaf Disease" in the *Statesman*. Briefly it may be said that the writer falls back on the old theory of our chemists —Messrs. Dixon, Schrottky and others—that the disease attributed to *hemileia vastatrix* is much more deepseated than the leaf, that the poison in fact is to be found in the blood, the sap of the tree, and that the remedy must have a renovating power far beyond any topical application. But against this view, once a favorite with many of the planters themselves, we have the results of the investigations by Thwaites, Abbay, Morris, Ward and Trimen, all dead against the sap-disease theory, and we have the fact that Mr. Schrottky although he began with inoculation was fain to revert to topical applications after the example of Morris and more lately Storck. Nor can the cause of the disease given by the *Statesman* writer be accepted without dispute. The artificial culture and especially the pruning of the coffee tree was a matter of fully thirty years' standing in Ceylon before the leaf-fungus made its appearance. As we mentioned yesterday, Mr. R. B. Tytler introduced the practice of coffee pruning from Jamaica before 1840, and the first appearance of the *hemileia* was in 1869, and that not in an old district where the coffee had been arti-

* It does not seem desirable that the trees should mature fruit, until fully four years old.—ED.

ficially treated and pruned for a generation, but in a remote, young district, where the plantations were still in their infancy, and where, since then, they have yielded heavy crops for years without being so much troubled as other and older districts which were visited later on by the dire enemy. Curiously enough, only during the last few weeks, the theory has been revived in Ceylon that in pruning—the free use of the knife—the coffee planter has one of the best means of fighting leaf-disease, and we believe the opinion is very general that for some seasons there has not been enough of pruning and handling owing to different causes, chiefly want of money, on most of our coffee plantations. But apart from this we have the case of a Dimbula proprietor who, in the face of warnings from his neighbours and old planters generally, has systematically gone in for severe pruning (accompanied by liberal cultivation) for five years back, and whose property, in place of being ruined as was prophesied, has steadily given crops much above the average, promising well even in this year of almost universal short crops. So again we have had one of the oldest planters in Uva declaring that he has no fear of leaf-disease if he is allowed the free use of the knife, and there are not a few now who are coming round to a belief in heavier pruning as one means of getting crops from plantations still afflicted with the leaf fungus. Of course, we may be told that the treatment referred to must inevitably wear out the tree sooner or later; but five years of steady cropping is a long period in the middle life of a coffee plantation in these days, and when the trees still continue to look as fresh and vigorous as any in the district, it is hard to gainsay the teachings of experience even when opposed by so logical a theory as that propounded in the following article :—

A discussion is at present going on at home between Mr. E. M. Holmes, F. L. S., and Dr. W. T. Thiselton Dyer, on the "Causes of Coffee Leaf-disease." So far as we can make out from a perusal of the correspondence passing between these two eminent gentlemen, they are both arguing beside the question. It is admitted on all hands that weakly or badly nourished plants are more liable to be attacked than are healthy bushes. This, however, affords no evidence as to the cause of the disease, although it seems to confirm the opinion we have always held, that there is no such thing as leaf-disease at all. If it were a leaf-disease only, all bushes would be similarly liable to attack; but if it is, as we believe, a root-disease, then the comparative immunity from attack enjoyed by the healthy plant is intelligible. Mr. Holmes, while not admitting this, unconsciously brings forward evidence in support of it, when he says that the disease would be much less deadly if all the coffee plants in Ceylon had been newly obtained from a wild source. No doubt, because the causes which we affirm have tended to bring on the disease, would never have affected the "plants newly obtained from a wild source." Mr. Holmes seems to think that the comparative immunity enjoyed by the Liberian coffee, is "because the texture of the leaves is unfavourable to the development of the fungus." There may be some ground for this, but we suspect that the leaves of this variety will be equally affected with the others, after a few years of the same treatment. Dr. Dyer recommends a renewal of the plants on an estate from seed collected after the fashion of pedigree grain. This is equivalent to telling planters to bear with the ills they have, and sacrifice their fortunes for the benefit of their successors. Pedigree wheat can be well selected after ten years, but as the coffee plant does not bear seed during its first year, thirty years would elapse before a carefully selected supply of seed could be obtained, and after all the result would only be problematical. This proposal of Dr. Dyer's also admits the correctness of our theory that the disease is a radical one; else why try to get rid of it by such a thorough-going renewal process?

Regarding the comparative immunity enjoyed by Liberian coffee, Mr. Holmes says :—"I attribute the fact that Liberian coffee is *less subject* to the disease, to the plant having had as yet hardly time to have its vitality lowered by excessive bearing, or by growth in soil deficient in metallic nutrition for the plant." This shows a true understanding of his subject. In this sentence, Mr. Holmes hits the two principal causes of disease—"excessive bearing" and "deficient nutrition." In tea, there are two other causes operating to deteriorate the plant, and these are the cultivation for leaf as opposed to seed, and the excessive pruning to which the bushes are subjected. This difference allowed for, the causes of leaf-disease—so called—in both coffee and tea plants are the same.

We shall now direct attention to these causes somewhat in detail. Nature, in its production of fruits and seeds, works under fixed rules, and these rules we deliberately set aside. In the cultivation of coffee, the financial exigencies of the industry make it imperative that we should, if possible, obtain a heavier crop than would be produced under the ordinary operations of nature. To effect this, we resort to pruning, which has the effect of a stimulant on the plant, constraining the plant to throw out fresh flowers and seed-bearing shoots. There would not, perhaps, be so much harm in this, if we helped the tree by a little nourishing treatment, but herein we fail. When a man has extra work to do, he must be well rested and better fed than usual: otherwise his power to perform that extra work is weakened. This does not seem to have been taken into account in coffee cultivation. Year after year we strive for an extra crop, without exerting ourselves much in the way of feeding the hard-worked plant. This then is the first cause of disease. Next comes what Mr. Holmes calls, "soil deficient in metallic nutrition for the plant." In other words, the artificial forcing of the plant results in depriving the soil of what is commonly known as plant-food. Now, in the cultivation of ordinary crops, the farmer knows that, if he wants a good crop, he must manure his land, and if, from whatever cause, he is not in a position to apply manure, he, as a matter of course, looks for a poor crop. This sort of commonsense does not enter into tea or coffee planting; good crops are expected year after year, and thorough manuring—in fact, manuring at all—is the exception rather than the rule. Judicious pruning may enable this end to be achieved for a time, but a period arrives when nature will not stand this sort of treatment longer; and such results as this disease immediately show themselves.

Now, let us look at the treatment to which the tea plant is subjected. The pruning process seen in the coffee plant is very much aggravated in tea cultivation. During the winter, when the plant is resting, pruning takes place, and it is a much more thorough process than it is in the case of the coffee. There is also this to be said, that each time the bush is plucked, it undergoes a serious pruning, and that too of the most valuable leaves and shoots the struggling plant possesses—viz. the very youngest and the most active in the economy of plant-life. In December, we will say, the plants get their annual heavy pruning, and shortly thereafter growth begins. The very act of pruning compels the plant to make

a violent effort to throw out new leaves—new lungs—to replace those of which it has been so ruthlessly shorn. As this growth progresses, the planter is on the look-out for it, and as soon as it assumes the dignity of a "flush," it is pounced upon by the plucker. This process is repeated, perhaps, a dozen or more times during the tea season; each time the plant puts forth an effort, as surely is that effort nullified by the work of the plucker. Is it to be supposed that a plant so treated can long escape the ravages of disease—the precursor of decay? But there is worse behind. The ravages of blight have been found to be much more severe on gardeners having indigenous or hybrid bushes, than on those with the bushes of the ordinary small-leaved China variety. Now, under ordinary circumstances, this fact would militate against our theory, because the indigenous variety, and the many hybrids produced from a crossing of it with the China bush, have not been cultivated for so long a period as the ordinary China has. But the indigenous and hybrid varieties suffer very much more under the pruning knife. We do not simply mean that, being larger in every way than the China, the hybrid feels the cutting down more. We refer to the habit of the hybrid rendering it more sensitive to pruning. All who know the tea plant thoroughly must have observed that, while the China variety has the habit of a bush, the hybrid is a tree. A China seedling develops laterals almost as soon as it comes above the ground, whereas a hybrid seedling does not throw out these side branches until the main stem has assumed the form of a young tree. In conformity with this difference of habit, the China, if unpruned, would not grow high, while a hybrid, similarly treated, would assume the habit and attain the growth of a forest tree. We speak under correction, but are not aware of a China plant ever having grown to a greater height than seven feet. This is the greatest height we could induce one to attain, although we left it unpruned for several years. Thus it happens that the China variety does not suffer so much from pruning as does the hybrid. The former is a bush, and pruning only keeps it a bush, while the latter being a tree, is, so to speak, compelled by heavy pruning to assume the habit of a bush. This also explains why the blights on tea are of comparatively recent date. With regard to the recent occurrence of disease in connection with coffee, it is accounted for by the fact that only within comparatively recent times has heavy pruning, or pruning of any sort, been resorted to. One more cause of disease in connection with tea, and we are done. The fiat which went forth at the creation, that the fruit-tree should yield fruit after his kind, whose seed was to be in itself, indicates the first law of vegetable nature, that the first object of a plant is to propagate its own species, and hence we find all vegetable life at its best just as becomes fit for reproduction. In this respect the coffee-planter does no violence to nature, except in that he expects the plant to be in a chronic state of making violent efforts to produce a large quantity of seed. With tea it is very different. The planter cares nothing about seed, leaf being the craving of his soul. With this object in view, his whole energies are bent on thwarting nature and preventing the growth of seed. Is it to be supposed that a plant can long remain healthy when its natural instincts are not only interfered with, but directly opposed and crushed? In this we see a sure cause of disease and general debility. The absurdity of regarding such a blight as simple "leaf-disease" will thus be seen. When an eruption breaks out on the human skin, the skilful physician immediately treats it locally, but he does not make the mistake of considering the eruption only a skin disease. He treats it locally to relieve the pain, but he endeavours to remove the eruption itself by acting on the source. This will most probably be the blood. There the disease has its seat, and, if the cure is to be permanent and thorough, the blood must be purified. The eruption on the skin is not a disease but a symptom, which draws the physician's attention to the blood. So with the leaf blight; it is but a symptom of the radical disease in the life-blood of the plant, and can never be cured by topical treatment. It may be mitigated, but we have no hesitation in predicting that mitigation will prove but transient at best.

AN IVORY FAMINE.

Notwithstanding the introduction of "celluloid" and other substitutes for the real article, the demand for ivory increases year by year, and year by year the supply falls off. Not only is the quantity of elephant ivory, both from Asia and Africa, rapidly diminishing, but the teeth or tusks of the walrus, whale, and narwhal, which are so highly prized for many purposes where their fine texture and close grain render them superior to elephant ivory, are similarly growing scarcer every year. If it had not been for the large supplies of fossil mammoth ivory which we have received from Siberia—the relics of a bygone age, when Northern India was the playground of monster tusk-bearing, elephant-like animals whose bodies, suddenly overwhelmed by an avalanche of ice, are still to be met with, kept in a state of perfect preservation by the most powerful and efficient refrigerating machinery of Nature herself—if it had not been, we say, for this extensive, but necessarily limited, source of supply, the price of ivory would be much larger than it even now is, when a plain ivory paper-knife, of ordinary size, after passing through the necessary cutting and polishing operations, is worth half-a-crown an ounce. The *Engineer* reports that the rapid advances in the value of ivory are causing some uneasiness in the market. At the last quarterly sale, which closed on the 28th ultimo, there were only 81 tons offered, as against 122 tons offered in April 1881. The falling-off was mainly owing to the continued scarcity of Cape, and the limited supply of West African ivory, of which altogether only 12 tons were forthcoming. From Zanzibar and Bombay there were 33 tons, 24 tons from Alexandria and 9 tons from Malta. Prices consequently have gone up from 3*l* to 4*l* per cwt. The stores in the docks this year amount to 133 tons, compared with 213 tons for the corresponding period of last year. One importer at Sheffield has received 522 tusks, which, he says, will all be cleared out in a fortnight. These tusks represent 276 elephants, and it is argued that, if one ivory cutter alone can get through so many in so short a time, there is some fear of the elephant being relegated to the lost genera of animals. It is time that some steps were taken for the preservation of this valuable animal in Africa similar to those which have been adopted in India and Ceylon, and the authorities in our West African colonies might turn their attention to the possibility of devising some means to attain this object. In the meantime, cannot some inventive genius discover the means of utilizing the scraps and shreds of ivory which ivory-turners necessarily produce in such quantities, either by reducing them to a pulp, and pressing them into the desired shape, or into powder, which may be afterwards solidified?—*Colonies and India*, 19th May.

COFFEE PULP AS A MANURE.

By JOHN HUGHES (late of Ceylon).

Coffee pulp, as understood by planters, consists of the outer skin of the ripe cherry, together with a portion of the gelatinous, saccharine and somewhat

glutinous material which envelopes the seed or beans.

In the process of pulping the ripe fruit is brought in contact with revolving cylinders, furnished with small holes sufficiently large to allow the beans to be washed through into the fermenting tanks, while the pulp is carried by a stream of water through spouting into an adjacent pit, where it remains usually for some weeks until crop time is over.

It is then customary on most estates to apply this refuse pulp either alone or mixed with lime, or some concentrated manure, as a dressing for the trees; but there appears to be great difference of opinion among planters as to its merits as a fertilizer.

Some say that it is of little use in itself, and is very slowly decomposed in the soil, cases being mentioned where, upon digging up the soil twelve months after application, the pulp has been found in the same state as when removed from the pit (Grigson's pamphlet on *coffee culture*). Others, however, contend that when mixed with a little artificial manure the results, both as regards the production of wood and fruit, are very decided.

This uncertainty respecting the action of pulp as a manure may, I think, be traced to a difference in the treatment previous to application. In the one case it has been allowed to remain for weeks in a heap exposed to heavy rainfall and to the action of waste water from the pulping-house, whereby all the valuable salts of potash and soluble nitrogen compounds have been removed, leaving only a mass of woody fibre or cellulose, which would be of no more use as a manure than ordinary sawdust.

In the other case, the pulp has been regularly removed from the pit and mixed with cattle dung, or at least made into a heap away from the action of the running stream, and subsequently mixed with soil and lime to form a compost. At any rate care has been taken to preserve the valuable salts, and to effect the decomposition of the vegetable tissues previous to being applied to the coffee trees, and the results are consequently said to be satisfactory.

However, in order to form some practical opinion of the real value of coffee pulp when carefully treated, I took the opportunity, during my residence in Colombo, to prepare a sample of this material for future analysis on my return to England.

Some very fine ripe cherries were sent me by post in a tin case from the neighbourhood of Badulla, and were taken in hand and shipped immediately on arrival. Every 100 parts by weight of cherry yielded in round numbers 40 parts of pulp, and this gave on analysis the following results :—

Composition of Fresh Coffee Pulp—

Water	78·310
*Organic vegetable matters ...	19·860
**Mineral matters (Ash) ...	1·830
	100·000
Containing Nitrogen	·330
**Consisting of :—	
Potash	·874
Soda	·031
Lime	·184
Magnesia	·037
Oxide of Iron	·029
Phospheric Acid	·084
Sulphuric Acid	·062
Chlorine	·047
Silica	072
Carbonic Acid	·410
	1·830

From the above results it will be observed that fresh pulp, if *taken direct from the pulper*, is really a very useful and valuable material, and, though inferior to ordinary cattle dung as regards the proportion o phosphoric acid, lime, and nitrogen, it is superior in the quantity of *potash*. Thus, in 100 parts of farmyard manure, we may assume that the above constituents are present in the following proportions :—

Nitrogen	·55
Lime	·70
Phosphoric Acid	·25
Potash...	·50

If, however, pulp be exposed to continued washing, as is generally the case, the agricultural value is certainly less than it would appear to be from the above analysis. For I found by actual experiment that, if 100 parts of pulp were allowed to remain in contact with 10,000 parts of cold water for 24 hours, there were dissolved out the following :—

Organic matters (soluble)	6·543
Mineral matters (soluble)	1·201

In other words, $\frac{1}{3}$ of the organic matters, and $\frac{2}{3}$ of the mineral matters, including the potash salts, were washed out with cold water after saturation for 24 hours.

It is therefore evident that planters would do well to remove the pulp directly from the separator, and not allow it to remain in the pits even for a day, and certainly should not permit the continued action of running water.

At the present time, when crops are short and prices low, it is certainly imperative that planters should lose no opportunity of obtaining from a residuum material like pulp all the possible advantages of a useful manure.

It should also be remembered that properly decomposed vegetable matter must ever be a most valuable application to soils naturally light and porous like the majority of Ceylon, India, and Jamaica coffee estates; for thereby the supply of carbonic acid is increased, and the mineral resources of the soil are more easily rendered available as plant food.

As regards the best method of preparing coffee pulp, I would suggest that, where cattle or pigs are kept, it should be mixed with the manure from the sheds as soon as possible. But in other cases composts should be made of pulp, bones, and any other fertilizers that may be at hadd. If nothing else be available, it should be mixed with a little lime and soil, and remain well protected from rain for a couple of months. When economy is absolutely necessary on all estates, it may be useful to direct attention to the natural advantages of coffee pulp when properly prepared as a manure.

Analytical Laboratory, 79, Mark Lane, London.
—*Planters' Gazette.*

THE "TROPICAL AGRICULTURIST."—A native gentleman writes :—"It will be very useful and accomplish a long-felt want if the London and New York Price Currents are included in the *Tropical Agriculturist.*" We purpose adopting this suggestion, beginning with the July issue, the first of a new year. The June number is now complete, but we have to add to it a full index for the yearly volume, which can then be bound up. The index is in hand. A Nawalapitiya planter writes :—"The T. A. is a special comfort to me and I am looking forward to this month's No."

EXACUM MACRANTHUM is a native of the mountains of Ceylon, where it is found at an elevation of about 6,000 feet above sea-level. It is a fine ornamental plant, belonging to an order—Gentianaceæ—which furnishes our gardens with by no means a few showy things. It grows about a couple of feet in height, has large, glabrous, glossy leaves, gradually becoming smaller as the terminal corymbs of handsome dark rich purple blossoms are reached; these measure about 2 inches in diameter, the yellow eye and large yellow stamens forming a striking contrast with the purple of the corolla. Now in flower in No. 8 house at Kew.
—*Gardeners' Chronicle*, May 26th.

Correspondence.

To the Editor of the Ceylon Observer.

THE BORER IN COCONUT TREES.

Johore, 22nd May 1882.

DEAR SIR,—I reply to "Sigma"'s letter, I have to state :—

1—Salt should be applied to every tree twice a year.

2—The seasons for applying it are at the beginning and end of dry seasons.

3—The natives think it is of use applying salt to attacked trees, but I doubt it, as I have placed a "borer" in salt, and it did *not* kill it.—Yours truly,

E. E. A.

THE ALOE FIBRE ENTERPRIZE IN MAURITIUS: WHAT IS TO BE DONE IN CEYLON.

Colombo, 10th June 1882.

DEAR SIR,—I enclose two cuttings from the *Mauritius Merchants and Planters' Gazette*, shewing that planters there, are also turning their attention to new products, to remedy the drawbacks attendant on having all one's eggs in one basket :—"We have to record the formation of another New Hemp Estate Company, viz : The *Vale* and *Black River Hemp Estates* (to include the estates : 1°. The *Vale*, 1,300 acres, partly under aloe ; 2°. The *Carreaux*, 200 acres, under aloe ; 3°. The *Salines*, 700 acres, nearly all covered with aloes ; 4°. *Petite Rivière Noire* and *Belle Vue*, 1,600 acres in lease.) Nominal capital, R500,000." The product which is now being extensively cultivated there is *aloe fibre*. There are already five Companies established for its cultivation, the aggregate capital of which is R800,000, and now another has been formed to work 4 hemp estates with a Nominal capital of R500,000. The shares of these nompanies are mostly at a fair premium, and it appears that a new gratense" has been invented, which greatly improves the quality of the fibre, with an enormous saving in time and expense. Mauritius hemp ranks next to Italian, and is worth £30 to £40 per ton in London. Now, as every variety of the "aloe" grows well in Ceylon, why, may I ask, is its cultivation in our lowcountry to be neglected ?

If we had a Government worth its salt, we should have large prizes offered for the successful cultivation of say 100 acres. Government should offer a prize of R10,000 to any planter who could prove that he had successfully cultivated a large area over a period of three years. If twenty planters each claimed and received the reward, it would be revenue well invested.—Yours truly,

C. S.

P. S.—Of course the only drawback to its cultivation upcountry is the cost of carriage of so bulky an article. Probably the yield of fibre might counteract this :—

MORE OLD LEDGER TREES RICH IN QUININE, IN DIMBULA.

Galkandewatte, Lindula, June 10th, 1882.

DEAR SIR,—I send you copy of analyses made by Dr. B. H. Paul of samples of bark taken in January last from five of the calisaya trees growing on Ardneven estate at an elevation of about 5,200 feet. These calisayas are from seed sent by the late Mr. Melvor to Mr. H. Humphreys in August 1875, and were planted out in September 1876:—

	Crystallized quinine sulphate.	Crystallized cinchonidine sulphate.	Cinchonidine (alkaloid).
No. 1	8·40	trace	—
,, 2	9·03	0·30	trace
,, 3	8·24	trace	trace
,, 4	9·10	trace	trace
,, 5	9·75	0·70	trace

Dr. Paul remarks:—"The samples received from you are very good : much above the average quality of bark. From the analysis, I should say that they are all from the Ledgeriana varieties of calisaya which is the best of all the cinchonas."—Yours faithfully,

JOHN TILLY.

[We congratulate the proprietors of these fine trees, which are undoubtedly of the Ledger variety, the analysis practically shewing quinine only.—ED.]

THE FERMENTING OF COCOA.

Pallekelly, Kandy, 12th June 1882.

DEAR SIR,—In response to "Aberdonensis" I may state that cocoa usually takes eight or nine days to ferment.—Yours faithfully, FRED. H. GIBBS.

PLANTING NEWS FROM THE PEAK VALLEY, CEYLON.

Maskeliya, June 12.

SIR,—What has become of the monsoon? Have you got it in Colombo? As a proof of the mildness of the weather here, I noticed yesterday that my neighbour on the opposite side had a large amount of bark out drying on his barbacue. He and I often differ as to whether the sun has an injurious effect upon shavings ; he evidently is not yet a convert to commonsense, as I observed he had covered his bark with mats, to protect it from the rays of old Sol, who was as brilliant as if we were still basking in the brightness of February ; and this proves (if any proof were wanting) the correctness of your views as to the unseasonableness of our seasons recently. No man who comes to take an unprejudiced view can doubt that our short crops during the last five years arise chiefly from this cause.

By the bye, do you think the blessing of God can follow the labours of those who persist in working on the sabbath ? There is surely time enough during the week to have one's cinchona bark dried, without hurting the feelings of such as from youth upwards have been led to look upon the sabbath as a day of meditation.

We are deeply indebted to the writer who lately, in a series of able letters from this valley, defended our district from the ungrateful detractors, who think it their duty to go about the country repeating, in season and out of season, all the hard things they can imagine on the subject of our soil, climate, and prospects. Without being a sanguine man, I think I can honestly say that, from the church upwards, for at least two miles, one can see as fine a sheet of coffee, and as promising growth of young cinchona, as any at present in the island.* Then this coffee has had the benefit of careful treatment and judicious cultivation, and it would be folly to expect that without these, coffee, debilitated by leaf-disease, can go on year by year bearing the fine crops, which the owner of these estates assures me he has gathered from them.

Have you heard of the sale of a share of Kelaniya estate to the wealthy gentleman who recently visited our shores in his own yacht? I feel confident it will

* And no finer cinchonas could be wished for than on many of the estates "from the Church downward"—ED.

turn out a good investment for him; at the same time I congratulate the vendor on the good price he obtained for his really valuable property.

To anyone who has not visited this district for the last few years, it would be a pleasant surprize to see the flourishing fields of cinchona which are cropping up on all directions. We are not here tied to any one variety. Near the foot of the plain we have some of the most valuable ledgers in the island; on the opposite side of the valley, the calisayas, which it was once the fashion to decry, are slowly but steadily winning their way to general favour; officinalis flourish on steep slopes at the higher altitudes; and succirubras grow well everywhere. Talking of ledgers and calisayas, it has struck me that these fine varieties differ somewhat in their habits from the coarser but less delicate kinds. I have noticed that they have a tendency to drop their leaves, and assume the appearance of wintering, just as a friend tells me the Ceara rubber do in the lowcountry. In this connection I heard a good story the other day of one of our omniscient visiting agents. He, when reporting on an estate on which there were many rubbers, set them down as three-fourths dead. A month after, he had again occasion to visit the same part of the country, and, seeing all the supposed dead trees covered with healthy foliage, he soundly abused the superintendent for trying to sell him by sticking, as he said, jungle leaves on the dried Ceara stems!! Yet such are the men who undertake to teach us our work.

Long live the "old rag" to be the friend and encourager of the steady, the industrious, and the honest, but the scourge of the lazy, the bigoted, and the fanatic. The hard times are making us nearly all teetotalers.—Yours &c., J. S. W.

COFFEE CROPS IN DIMBULA, CEYLON.

Tillicoultry, Lindula, June 13th, 1882.

Dear Sir,—I think it only right that anyone honestly able to say a word of hope and encouragement for the unhappy coffee (Arabica) proprietors and their scarcely less unhappy mortgagees, should do so. The hope I have is that the big blossom out in this district from April 10th to 16th has not failed to nearly the extent some gentlemen insisted it had done. For myself I was almost coming to their way of thinking, but within the last few days the not excessive rain and occasional sunshine has started the berries in swelling, and, although these have remained dormant for two months, I think there is every chance of their finding their way down to Colombo. There are I know many estates in this district which have blossomed well, and I believe—in fact I know—that such has been the case in other high districts, and the hope is that in all such estates prospects have equally improved as here. The cause of the want of growth in the berries I attribute to the unusually long continuation of the dry winds and great heat after the middle of April. I have had experience of Dimbula since 1867, and have never yet heard of a blossom failing from drought.

The coffee enterprize I fully believe has suffered as much damage by croakers and wreckers whom we find amongst our fellow-colonists as by all the leaf-disease and grub we have had. These pessimists (the croakers, etc.) have by their groanings and advice done much to discourage the proper cultivation of estates at the very time it was most required, thus immensely aiding our insect and fungoid enemies.—Yours faithfully, PHILIP M. ANSTRUTHER.

[Tillicoultry is the estate we had in view the other day when referring to the best crop, probably, of the coming season; and yet the laird of Mattakelly, less than a score of years ago, dissuaded a Colombo V. A. from investing in the jungle at R20 per acre. Coffee was down then, and it is *down* now: is it not to revive in crops as well as prices? There is a good deal in what Mr. Anstruther says about the neglect of cultivation in pruning and manuring especially.—Ed.]

CINCHONA BARK *VS.* SHAVINGS.

14th June 1882.

Dear Sir,—I have just read your very interesting article on hybridization and *C. robusta*. The analysis given for renewed *C. robusta* is said to have been obtained from "bark." I conclude therefore "shavings" were not intended, but still, these terms being often applied in rather an indefinite sort of way, I would suggest that, until we get fairly into the way of using them, the designations "bark" and "shavings" be italicized in order that no doubts may exist in the minds of your readers. This is very important.

ROBUSTA.

P.S.—Can you give us any figures for renewed *shavings* of *C. robusta*?

[The Dimbula proprietor concerned will oblige us by saying if he shaved the second time: at nine months, the renewed bark could not be much more than a shaving.—Ed.]

HOW CINCHONA BARK IS SOMETIMES THROWN AWAY BY LONDON BROKERS: A REMEDY WANTED.

June 14th, 1882.

Dear Sir,—A few hints from your able pen would be of immense value to the unfortunate growers of cinchona, who have large clearings of this dying out, and who are in consequence greatly in need of money. Would you, therefore, greatly oblige me, by showing me the most profitable way of selling my bark, as it is heartrending to know that the middlemen sitting in their chairs all day should be reaping all the profits, men who have never risked a farthing in the speculation of cinchona cultivation?

That the following should have actually happened in the 19th century will hardly be credited:—A parcel of bark was sent to the London market, of which 60 lb. were taken out and given to a doctor friend to dispose of. The parcel was sold for 3s per lb, whereas the doctor got 13s a lb for his, and this was even resold again for 17s a lb. I have read in your paper for many years with considerable interest the various London brokers' reports on the cinchona market, and I have gathered from them that the intending purchasers do not have the bark analyzed unless it is a large parcel, and then the wastage in distributing samples is considerable, and probably samples are only given to the favored few.

A person who was connected with the largest sugar business in London told me that in the sugar trade two samples were taken from each shipment of sugar and sent to the two highest authorities to be analyzed, and the shipment was then sold by the mean average analysis of the two. Now, sir, would it be advisable when sending home a parcel of bark to get it analyzed by two of the leading authorities in analyzing bark, and then selling it by the mean analysis, and giving a guarantee as well? By this means the smaller chemists would buy with confidence whatever they required, as one chemist at the time might require a red bark giving a large proportion of cinchonidine, and another might require one giving a quantity of quinidine. Whereas now they have to pay very high prices from the purchasers to obtain these, and they were unable to buy at the rate, not knowing what the bark contained, never having received any from the broker for analysis, nor been told by them what it con-

tained. My trees having been shaved I shall have no bark to ship which could be sold by its appearance for show purposes.—Yours faithfully,

LIVE AND LET LIVE.

[We suspect the remedy must be provided in local sales for shipment to the Continent of Europe and to America. We heard the other day of the very fair arrangement under which Messrs. Volkart Brothers buy, on analysis, for the Continent. This house has shipped an enormous proportion of the season's exports, and, considering the magnitude of London charges and of the American differential duty, we think there can be little doubt that local sales *ought* to be the most profitable to the Ceylon bark cultivator. At the same time, complaints are not wanting in respect of local sales: the way in which good twig bark and shavings are sometimes sacrificed for 'an old song' in Colombo, while again parcels of decidedly inferior stuff, according to age and planting notions, realize a price beyond expectations, is unaccountable.—ED.]

CINCHONA CLEARINGS.

SIR,—The failures in a cinchona clearing are usually attributed to unsuitable soil, want of drainage, or to bad planting, but may there not be another and unthought-of element in the matter? May not the rays of the sun on the young TENDER STEM of the plants have something to do with the numerous failures experienced by I may say every planter without exception. Would it not therefore be worth while to try sheltering the young plants by wrapping some suitable material: moss, coconut fibre, newspaper, old gunny stuff: or anything else, loosey. round the stem when being planted out? The method might also be adopted for coffee supplies, I am aware that young plants are generally sheltered by twigs with leaves upon them or by pieces of bark, but in such cases the young leaves of the plants are smothered up and deprived of the influence of the sun in causing the flow of sap.

Useful or useless, I offer the suggestion for the consideration of planters of CINCHONA.

LOCAL ANALYSES AND SALES OF CINCHONA BARK.

June 16th, 1882.

DEAR SIR,—I duly read your footnote to my letter, suggesting that the remedy might be by selling the bark in Ceylon on analysis, but the least said about a local analysis the better. These analyzers differ as much as chalk does from cheese, all giving a result well under a London analyzer's. Their object in doing this, and the reason why they are defended by the brokers, I leave to more competent hands than my own to dispose of.

I have given the local market a fair trial, and you can judge for yourself whether it is a fair one, even presuming the analysis was reliable. My experience of Colombo sales was that I could only get 20c. a lb. for branch and twig, and, on writing to the broker about this unsatisfactory price, and requesting him to have a subsequent batch analyzed, his reply was that it would do no good, as there was no sale for this on analysis. (Now, when my stem bark contains over 2 per cent of quinine, it is rather unreasonable to expect us to believe the branch and twig would only contain ·33 per cent.)

I see by last mail that Howard's quinine was quoted at 10s 6d per ounce, the equivalent being R6 in Ceylon. Now supposing red bark by Ceylon analysis contains only 1 per cent of quinine, and 5 per cent of other alkaloids (all valuable), it would take 100 oz. or 6 lb. to make 1 oz. of quinine, and, considering the alkaloids are so good, we might expect at the least R1 per lb. for this (the quinine value alone being that), but I regret to say only 50c. a lb. can be obtained for this bark locally.—Yours faithfully, LIVE AND LET LIVE.

[It is a pity that the medical officers in the planting districts are not qualified analysts to help the cinchona industry.—ED.]

HYBRIDS AND CROSSES.

June 15th, 1882.

DEAR SIR,—In your issue of the 9th instant, I notice Mr. Gammie takes me to task for having, in a previous letter, represented him to have said that hybridization amongst cinchonas never took place. I have not his former letter at hand to refer to, but suffice it that he points out the mistake, and I trust he will now allow me to apologize to him for it. He will, however, kindly remember that my former letter (written in joke rather than earnest) was in joint reply to another communication in your paper on the same subject. And I would here add that I most sincerely trust that nothing I did say in it may have caused *even a shade* of annoyance either to himself or to Mr. W. Smith: for to no two men is the unbounded respect I feel for them more absolutely due, for their intelligent and successful exertions in the development of the cinchona enterprize, and in turning the same to effectual account, to the benefit of multitudes. Truly has Mr. Gammie accomplished the latter in his successful attempts to produce a reliable febrifuge, and *yea even* quinine itself at a sufficiently cheap rate; and proud and happy may we well feel over it all. Still there is one point I must yet dare venture to join issue with him; and, I fear I must add, with yourself in your excellent and interesting review of the subject of his letter. I maintain, though on other grounds quite, that there cannot be such a thing as hybridization amongst the true cinchonas. And as to my remarks thereon in my previous letter, I see that Mr. Gammie passes them over unnoticed! He mentions that the two varieties of tea are said to have a common origin, and that, as it takes two *distinct* species to produce a "hybrid," the term is in this case a *misnomer*! This I am quite willing to grant; but I say that there is quite as little actual proof that the varieties of tea are of common descent as there is to the contrary in the case of the cinchonas, and that some sounder basis of argument than mere surmise is required in either case, even supposing the question really hinged on this point only or at all. Marked differences, granted, there are, both in outward appearance and habit, between the different varieties of cinchona, but none greater are there betwixt *officinalis* in all its forms, *succirubra*, and the numerous, *so-defined*, *calisayas*, than between a Shetland pony, a cart-horse, and the indigenous wild horse of Thibet—more like an ass in appearance than it is to either of the former, still it is a true "horse," and said to be the origina. stock a disputed question) from which all the different domesticated breeds of horses are descended, *outward appearance going for nothing*! Why? Because *structural difference* ranks it among "horses" instead of "asses"! And here the needful difference occurs to originate a "hybrid." Now, as regards all the hitherto cultivated varieties of cinchona, if I am *right* in my belief that there are no material structural differences between any of them—in fact, that they are one and all *true* cinchonas—then I say that the term "*hybrid*" may be a *convenient*, but is nevertheless an *incorrect*, term to apply to the crosses in any case produced amongst themselves; that they are mere *crosses*; and that to obtain a *bonâ fide* "*hybrid*" it is necessary to go farther, though not necessarily beyond the same

family. And I again revert to my former illustration: a cross between a true "cinchona," and *say* a "cuprea bark" tree. The latter I believe I am right in saying belongs to a group nearly allied to the true cinchonas, but possessing *structural* differences that separate its members unmistakably from the former, as do corresponding differences the *horse* from the *ass*, the *rabbit* from the *hare*, the *dog* from the *fox*, the *goldfinch* from the *canary*, or a *man* from an *ape*, not to mention in the latter case the God-bestowed, God-likening, *non-structural* gift *to man* of reason, or rather *soul* (for animals possess reasoning powers *of a kind*—who can doubt it?—and that they can be increased by culture!) forming as it does a barrier that an endless system of evolution can never overcome. Let *scientists* say what they like and outrage our instinct, that I take it, if the truth were known, clings to every clever man among them to the grave, and to their increasing discomfort, as they find themselves more nearly approaching it, causing them at the end to wonder despondently whether, or not, after all, their mighty intellects have not misled them into being spuriously rationalists under the deception of *materialism*. They want to find out what they are told they are not to know on this side of the *grave*, and because *they* can't do so *profess scepticism* in conceit engendered by dazzling discoveries. We may, for ought I know, have been "apes" in the first instance, but as "apes" only should we have remained to the end of the world but for that one gift *divinely* added—possibly when our animal sagacity had become sufficiently developed under an improving system of evolution, though I don't know that it has been shewn that monkeys are better monkeys now than in *the beginning—at least*, one friend of mine would speak feelingly to the contrary just at present!

But to return to cinchonas: I say again, cross any true cinchona with any member of an allied group or separate family (if this be possible) and the produce will be, in the true sense of the word, a "hybrid," but not otherwise. I may be wrong, and, in venturing the assertion, but suggest a point for men of science *obligingly* to explain.

To Mr. Gammie's queries, and those also of a former writer, as to the correctness of my statement with regard to the "hare" and "rabbit" having been known to interbreed "in" or "out" of confinement; the latter gave another equally good instance in the case of the "dog" and "fox," but he does not follow it to its conclusion, as to whether the offspring are fertile. On the other hand, I would add a more curious fact in the case of the "hare" and "rabbit": that the offspring at each succeeding generation *between themselves* gradually revert to the "rabbit," at least in appearance, and thus, may it not be presumed, the result of the cross would ultimately become obliterated, rather than a new species established (as scientists might prefer!)?

I may add another equally interesting (though irrelevant) occurrence in connection with the hare, and I think also the rabbit, that may not have come under your former correspondent's or Mr. Gammie's notice. I allude to superfecundity. A freak or feat of nature, rare though it be, it has been on more than one occasion verified beyond a possible doubt.

By the bye, I noticed in the papers that Jumbo is to have chosen out for him a wife from amongst the daughters of Asia. Now, supposing, as a result of the union, a young Jumbo puts in an appearance to delight the public and further enrich Barnum, how would it pay best to 'placard' him: as a hybrid "robusta," or the first elephant "mule"? For I am much mistaken if he would not have an undoubted right to either appellation on the score of anatomical differences existing between the Asiatic and African elephant that place them as two positively distinct species—differences as important as between a horse and a donkey, to go no further. Read all Sir L. B. has to say on the 'front' shot! X.

[The argument regarding the so-called two species of tea, is that a cross between them having become at once and permanently fertile, we are justified in regarding the parents, not as distinct species, but as well-marked varieties. When we have the same form of evidence in regard to the various species or so-called species of cinchona, then we can arrive at a similar conclusion to that which seems justified on scientific as well as popular grounds in the case of tea plants, Assam indigenous, China cultivated, and the resulting so-called "*hybrid* Assam." Species, after all, if the development theory be admitted, are merely forms or varieties which have, under certain conditions and in long lapses of time, assumed distinct and permanent characteristics. If two plants, however different in habit and foliage, will readily intercross and yield permanently fertile offspring, then we have good grounds to say of the parent plants that they are not strictly species, but forms, races, or varieties. What we want in regard to the cinchonas is a series of carefully conducted experiments and the results.—ED.]

CINCHONAS ON FLAT LAND.

DEAR SIR,—Can you inform me whether cinchona will, or will not, grow on flattish land? A planter told me the other day I was simply wasting valuable plants in planting them in some 15 acres of flat land—very little slope—that I want to put into cinchona succirubra.—Yours truly, CINCHONA.

[Dr. King lays it down in his manual that cinchonas absolutely refuse to grow on flat land, and that is generally our experience. We saw a marked exception in Java, however, a grove of magnificent succirubras, near Junghuhn's grave, growing on a perfect flat. But the soil was deep, free volcanic matter, though moisture easily percolated. The question, therefore, here, will be one of a subsoil so constituted as to allow of perfect natural drainage. If the subsoil is clayey and stiff, we fear disappointment will follow planting.—ED.]

COFFEE ROBBERIES?—Can anything *unusually wrong* be going on of late in the Uva districts? We all know that coffee-stripping goes on there, as elsewhere, but it has generally been supposed that it is carried on only to an infinitesimal extent. Today, however, we hear that buyers and curers of so-called Badulla chetty estates' parchment are alike simply astonished at the character of the berries now reaching them through natives. The beans turn out so large and fine and the outturn is so exceptionally good that many have come to the conclusion they must be derived from high and finely cultivated estates under European management! As this matter has lately been much discussed down here, we consider that we ought to put our Uva friends in possession of the facts, pointing, as they seem to do, to either thefts on the estate, or changing and mixing of coffee on the way down. Again we say "Oh. for a railway!" Until the railway is available, no trouble ought to be spared in securing the best form of a bushel sealed sample bag to accompany each dispatch. A common gunny bag *sealed* is next to worthless, for cannot the sides be cut open and re-sown, or cannot bamboos be inserted, whereby inferior coffee can easily be inserted to make up for those abstracted, and so made to agree with the bulk already tampered with? The weight of a sample bag is no safeguard, of course, for the addition of a little water can soon be made to compensate for the difference in weight and bulk created by the introduction of light and inferior coffee.

CINCHONA.—At a recent small auction of a mixed assortment of bark, held by Mr. John, prices generally went lower than at the previous sale. Some useful "succirubra" quill sold at R1·05. Twigs averaged from 17 to 25 cents.—"C. Times."

A GOOD GALL SOAP is obtained, according to the *Seifenfabricant*, by the following method: 15 lb. gallnuts are mixed with 250 lb. molten coconut oil, and the oil is then soaped cold with 125 lb. soda lye (38° B.). The soap is colored with 8½ lb. ultramarine, and perfumed with 12 oz. lavender oil and 12 oz. kümmel oil. —*Oil and Drug News.*

HARVESTING OF CINCHONA.—Mr. Frater of the firm of Walker & Greig here has invented the *simplest and cheapest* cinchona barking machine, that I have seen yet. It is simply two iron bars, set in a square iron frame, the bars revelving on their axis. The cinchona twigs or branches are pushed between the bars, and are crushed, which enables the bark to be easily removed. Cost of machine R15 only.—*Badulla Cor.*

THE CURRICULUM OF THE AGRICULTURAL EDUCATION course (under Mr. Robertson of the Madras Government Farm) embraces scientific and practical agriculture, chemistry, veterinary medicine and surgery, botany, geology, land-surveying and mensuration, book keeping and arithmetic. The course of training extends over three years. Besides attending lectures on the subjects just mentioned, the students undergo practical training out-of-doors in surveying, practical training in the laboratory in analysis, in the veterinary hospital in the treatment of cattle-disoase, in the botanical gardens in horticultural pursuits; while, on the farm, they are taught to perform the various operations of husbandry. Each student keeps a farm book, or a cultivation book, in which he enters the daily work of the farm, the cost of cultivation, the yield and value of the crops, &c. Every student must pass the ploughing examinations, of which there are three standards, increasing in difficulty with the progress of the training. We have, at present, forty-two names on the roll of the College. Of these students, twenty-two come from Bombay, Bengal, Central India, Mysore and Ceylon. Looking back over a period of now nearly fourteen years engaged in active efforts for improving husbandry in this part of India, I am of the opinion that the results of the last three or four years' efforts have been incomparably more encouraging than those obtained in the first ten years of the period, which I must attribute entirely to the influences set in operation by the work done in the School of Agriculture. The institution being the first of the kind established in India, and indeed the first ever established where caste prejudices had to be encountered, we had no choice but to begin on lines of a somewhat experimental character, though these were based on what has been established by long experience in Germany, France, the United States and other countries, where the State has long engaged largely in efforts for promoting agricultural education. We must, therefore, expect that the organization of the institution will need to be modified considerably as our experience in working it shows this to be necessary. One important modification now being introduced is in the direction of connecting the institution more immediately with the land administration of the Presidency, Government having just approved of a scheme, the basis of which is that the institution shall be utilized for educating and training in scientific agriculture a number of subordinate land revenue officials. When it is remembered that the Government of this Presidency employs many hundreds of subordinate officials in land administrative duties, not one of whom has hitherto had any means of undergoing a suitable training for his duties, the importance of the step just taken will be duly appreciated.—*Madras Mail.*

CEYLON TEA.—An English editor writes:—"I have tried your Ceylon tea. The sample you sent me had a perfectly unique flavour, which at first taste is not unlike *hay* tea, and I found most persons objected to it. But for myself I liked it very much, as a good, sound body, and it improved on acquaintance."

SUGAR ESTATE COMPANIES in Mauritius are paying 28·17 per cent profit!—and yet we travelled home in 1878 with a leading Mauritius estate proprietor who declared that the sugar prospects in that island were well-nigh hopeless, and that it was next to impossible for the Ceylon Company Limited to realize their property.

CINCHONA CULTIVATION IN NORTHERN AUSTRALIA.—A planter writes:—"You make no comments on that part of Poett's prospectus relating to cinchona, though you criticize fairly enough some other portions of the document:—'At the end of the fourth year the cinchona trees, of which there would be many thousands, would be ready for barking, yielding from 2 lb. to 3 lb. of bark per annum and of the value in the first year of four shillings a pound.' It occurs to the writer that Poett has stolen a march on us, and has the famous 'Verde' growing in those nurseries of his in that 'Rumjungle' (what's in a name?) plantation. It is just possible, however, that it may be the shareholders who are *verde.*"

YATIYANTOTA, 17th June.—The weather since Sunday the 11th has been very favorable for planting, although there have been strong gales, and I am nowplanting out tea as quickly as I can, and I hope to have finished the new clearings ere 1st of July. Tea and Liberian coffee look as well as ever, and the Governor, when coming to the new and rising district, should visit Dunedin and Mipitiakande, on his way to Yatiyantota, and see in them both in splendid condition, tea and Liberian coffee—tea at Dunedin and tea and Liberian at Mipitiakande. He might take choice samples from here now of Liberian parchment, finest tea and cocoas, all from trees planted late in 1880! The chief surveyor is up here. I hope this portends more land being cut out and more estates. No floods this year yet, and the district very healthy and coolies in fair supply.

RAINFALL AND ROADS IN SAN PAULO BRAZIL.—The *South American Missionary Magazine* contains information which shews that if railways are going ahead in the great coffee district of which Santos is the port, the roads in rainy weather (a rainfall about equal to that of Nawalapitiya, characterizing the mountain up which the railway trains are drawn) are next to impassable:—

From San Paulo the Rev. T. J. Scott gives a pleasing description of the kindness and hospitality of the people of that province, and, speaking of the weather, he says:—The weather here is quite cool, thermometer for last two months averaging about 72 deg. It is true we have had a great deal of rain. The weather generally is awful at this time of the year —rain, rain, rain; and not such rain as we have in England, but sheets of water! The rainfall at the sierra (top of the mountain up which the train is drawn) was last year 169 inches. When you consider that the rainfall in England is somewhere about 80 inches, you will be able to appreciate the difference. The rain here not only keeps the air cool, but cleans the dirty streets, which is much needed. There has not been any fever this year at Santos; Rio also has been healthy this year. The rains made the roads and streets impassable; the roads at any time are dreadful, even worse than they are in Spain. I went out for a ride last Saturday in an ordinary lane, and I nearly got "bogged." The horse sank down to about the middle of his body, and I got my legs in up to between the knee and ankle. I was just going to spring off and try to pull the horse out by the bridle, when he made a great plunge, and got on to *terra firma* again.

AGRICULTURAL EXHIBITIONS.—It has been decided that the most suitable sites for district exhibitions are those situated in the vicinity of the line of railway, and if possible, places of pilgrimage, such as Srirangam, Thirunamalai, Bellary, &c., and that the most opportune time would be when fairs and feasts are held, which annually draw a large concourse of people together.—*Madras Times.*

PROGRESS IN JOHORE.—Mr. Walter F. Garland head of the Johore Government Survey, was a passenger by the "Nizam," and went on by the "Rosetta" this evening. Mr. Garland is likely to lay out the first railway in Johore—a light line of some 20 miles on the metre gauge, which will probably be constructed and equipped for a sum under £4,000 per mile. It seems that the ex-Chief Engineer of the Ceylon Staff, Mr. Macnair, was lately out reporting on proposed railways in Johore and the Straits Settlements, his services being secured, we suppose, through the influence of his cousin, Major Macnair. Be that as may, Mr. Macnair made his report and then disappeared.

CEYLON COFFEE: THE LATE BLOSSOMING SEASON AND THE WEATHER.—A proprietor with good means of information in reference to estates north as well as south of Kandy and Nuwara Eliya writes with regard to the discussion on this question:—"Extraordinary heavy rain during December no doubt interfered with January blossoms (especially would they do this, if the bulk fell in the latter part of that month). But this would not have been of much account, if blazing, hot, *favorable*, 'simply splendid,' weather had followed in the following three months. Such unfortunately was not our experience; nor was it that of ———, who has been resident in the Kandy districts since December last. I learn he agrees with my theory that most extraordinary weather prevailed. Favorable weather not prevailing in January, February, March, it follows, as a matter of course, that the heavy rain in December under such circumstances is to be equally deplored with the rest, for we were cut off from getting good January blossoms at the lower elevations. Of course, a good deal would depend on *how* the rain fell."

SILK WORMS AND MULBERRIES.—We are glad to note a renewed interest in silk culture, and trust that it may not run into an excitement. Until silk culture becomes a home industry and carried on by those members of the family whose services cannot be otherwise profitably employed, it will not be a success. Inquiries continue to come for eggs. The first step in silk culture is to secure a supply of food for the worms. This must be some kind of White Mulberry or the leaves of Osage Orange. In many States there are hedges of Osage Orange which can supply food. Prof. Riley, who has experimented with this food, says, if, when the worms get large, they are not fed with the tender succulent leaves, but only the firmer ones, there will be no appreciable difference in the silk from this food as compared with that from Mulberry. Those who have no hedges of Osage Orange must turn their attention to establishing a plantation of some kind of White Mulberry. There is scarcely anything to add to what was said in March. In all the older States there are trees, mostly relics of the "Multicaulis mania," from which cuttings may be procured. We have before referred to the "Women's Silk Cultural Association" of Philadelphia, which we understand is free from any speculative motives, but it to act as a medium between the widely scattered silk raisers and the buyers, their chief object being to advice and instructs. The Corresponding Secretary writes that in the first year of their operations they sent trees to 20 States and eggs into 25 States, and that they received cocoons from 21 States. We cannot do better by our inquirers than to refer them to this Association. —*American Agriculturist*, June.

TEA GROWING IN SOUTH CAROLINA.—China's monopoly of tea production bids fair to be broken in upon from unexpected quarters. The tea crop on the experimental farm near Georgetown has been gathered and cured. It is pronounced superior in appearance, quality, and flavour to the tea ordinarily imported into this country from China, Japan and India.—*Public Opinion.*

LONDON COFFEE.—At the instigation of a Mincing Lane merchant Messrs. Wigner & Harland have purchased from shops in and near London 37 samples of so-called coffee, and have tested them. One sample was sold as taraxacum coffee, and contained no coffee; a sample of dandelion coffee contained 10 per cent., and a sample of date coffee 57 per cent of coffee. The other 34 samples were served in response to a request for "coffee," and of these two were composed of 100 per cent of genuine coffee, and 32 were composed of coffee varying from 7 to 68 per cent, mixed with chicory, "tiuings," dates, dandelion, and other vegetable matters. Of these mixtures 15 out of the 32 were labelled "a mixture of chicory and coffee," but 10 of them contained other matters in addition to chicory. Fourteen were sold without any label, and of the remaining three one was labelled "specially-prepared French coffee" (this contained 34 per cent of coffee), and the others bore a label announcing that they were "mixtures," but not saying of what. Of the 32 samples of adulterated coffee one contained over 60 per cent of coffee, four contained between 50 and 60 per cent, four contained between 40 and 50 per cent, 10 contained between 30 and 40 per cent, six contained between 20 and 30 per cent, six contained 10 per cent, and one less than 10 per cent. —*Chemist and Druggist.*

CINCHONA ANALYSIS.—A correspondent writes:—"I have heard complaints upcountry of the varying results of analyses of the same bark in different hands. It is difficult to sell small lots, none of which will pay to be analyzed, and the consequence is *very low* prices are offered for bark, even though over 4 years old. It is proposed that local analysts be asked to check for themselves:—Now the plan I would propose would be this: make every analyst out here check himself. Whenever a planter or a merchant wished to obtain an analysis of bark he should call in the assistance of a brother-planter or merchant, and (the bark being ready before them) they would proceed to divide it into two unequal parcels, exercising every care, however, that the subdivision of each piece of bark was precisely what it ought to be, in order that, if the analyst did his work properly, the same figures identically almost would be produced in each case. If the figures differed widely, I opine that, under such circumstances, no fees whatever would be demanded or paid. If the figures closely approximated then the double fee incurred would, until one's confidence was restored, be money well spent. A few trials on this basis, carefully conducted, might soon prove which of our analysts could be most trusted. The parcels of course would reach the analyst through different channels and probably at different times, so that he would not know that any connection existed between them, nor (which is very important) would he ever know when he was being cross-examined. A guinea is surely ample to pay for any analysis; yet we often hear of much higher fees. Parcels consisting of less than 1,000 lb. would scarcely bear this charge. Then what can be done with numerous small lots of bark (good, bad and indifferent) which often, generally owing to their smallness, realize very low prices? I would say put all these through a rapid machine, cutting or smashing them into small pieces of about the size of your finger nail; then draw as ample. The analyst, reducing this to still smaller pieces, would again draw his sample, and so make an analysis, showing what the bulk of mixtures was really worth."

FODDER PLANTS.

Tagasaste (Cytisus proliferus), Adelaide.

Dr. Schomburgh reports:—"The seeds have grown uncommonly well, the plant reaching a height of four to five feet. There is not the slightest doubt that this plant delights, not alone in our climate, but in any kind of soil and situation. . . . . I do not doubt a moment that this shrub, if sown on the sheep-runs, naturally well covered with soil, will soon become acclimatised, and will stock the runs with a new fodder plant."

Brisbane.—In these gardens the seed germinates freely in the open air, but makes but little progress in its subsequent growth.

Teosinte (Euchlæna luxurians), Adelaide.—Dr. Schomburgh reports:—"I have now cultivated it for the last three years, and no doubt it is one of the most prolific fodder plants. Notwithstanding the prevailing dryness of the two last summers, the hot winds did not injure it, the plants not showing the slightest effect on their leaves, which preserved their healthy green, while the blades of the other grasses suffered materially. The habit of throwing out young shoots is remarkable, to the number, in some plants, especially such as stand in a moist situation, of 50 to 60, with a height of five to six feet. There is one drawback. The plant, as I have already remarked, being essentially tropical in its habits, the ripening of the seed-crop will be problematical with us, as early frosts will kill the plant."

Jamaica.—Mr Morris reports:—Treated as a garden plant, the *Euchlæna* has grown well at Castleton gardens, but sufficient experience has not yet been obtained to express an opinion whether it will prove generally suitable as a fodder-plant. A good crop of seed has been harvested and widely distributed for experimental purposes in different parts of the island."

Madras.—The Agri-Horticultural Society report:—"*Euchlæna* (*Reana*) *luxurians* continues to grow luxuriantly, seed, and reproduce itself, with so little care and watering as to confirm the opinion expressed in last annual report, that it may be considered a success. It is particularly worthy of growth in private gardens, a few stalks of it giving a green bite to horses in the long dry weather, when change of food is so hard to get. . . . . As a single crop, with a given quantity of water and moderately good soil, the *Reana* will produce, in hot weather, a much greater bulk of green fodder than either lucerne or guinea-grass, which are most commonly grown in Madras for the purpose.'—*Journal of the Society of Arts.*

LOSSES OF NITROGEN BY NITRIFICATION IN SOILS.

According to Mr. Lawes, the amount of nitrogen carried through the soil by the rainfall, or rather washed out of it and discharged through the drain pipes, is very great. The extent to which the evil is considered to work will be readily seen by the perusal of a lecture of Mr. Warington which was inserted in *The Field* of the 25th ult.—one which will attract all the more attention from the fact that Mr. Warington is associated with Mr. Lawes and Dr. Gilbert in making those particular experiments at Rothamsted on which the conclusion has been founded.

Mr. Warington read a paper on the subject at a meeting of the Society of Arts on the 23rd ult., and after alluding to the evidence of the drain-gauge, which was clearly shown by a large diagram appended to the wall, stated that the field at Rothamsted, which is laid out in experimental plots, has a drain pipe at 2 ft. deep under every plot, and that an examination of the drainage water from these pipes not only confirmed the evidence derived from drain gauges, but showed that when salts of ammonia are applied as a dressing in the autumn, the process of nitrification in the soil has the effect of rapidly converting the ammonia into nitrates, to be washed out by the first heavy rains. In one case he said a distinct increase of nitric acid in the drainage water was traced to the ammonium salts within forty hours after their application, and he thought that the whole of the ammonia contained in them might be nitrified and become lost within a month after application.

In the discussion which took place after the lecture at the meeting of the Society of Arts, Mr. Darby called attention to the fact that this conclusion was diametrically opposed to the views taken, some twenty years since, by Professor Way, who made the discovery that the silicates in the soil have the power of arresting and absorbing ammonia whenever coming in contact with it. Nor was this all that he considered he had ascertained; for in one of his papers in the "Royal Agricultural Society's Journal" he seemed very positive that the silicates would retain with a very tight grasp the ammonia thus attracted. Mr. Darby thought the Rothamsted experiment, on which the speedy conversion of ammonia into nitric acid had been based, would have been more conclusive if the depth of the drains from which the discharge had been tested had been three feet instead of two feet; and stated that the clear, pure appearance of drainage water, when discharged from deep drains, had hitherto prevented the opinion being held that it contained nitrogen in considerable quantity; and further, he asked if it were not possible that the principle of nitrification had more powerful action in the land at Rothamsted than it would have in soils in general.

Dr. Gilbert, who was in the chair, alluded to these several points, but gave most prominence to the apparent purity of drainage water to the eye being no evidence, as it had been proved that when most clear and sparkling it contains a large quantity of nitric acid. As to the character of the Rothamsted soil he considered it neither very fertile nor very poor naturally, and rather heavy than light; consequently he thought it must be considered of a fair average for test purposes. The silicates he considered would be very likely to attract ammonia by decomposing its base, but the experiments at Rothamsted proved that they retained it but a short time.

Mr. Warington, in his reply, admitted that the drains in the experimental field at Rothamsted would have been better for the test of the drainage water had they been placed 3ft. deep; but said that the draining was effected as far back as 1849, when the system of shallow draining, introduced by Mr. Smith, of Deanston, was commonly practised. It may be remarked as rather singular that neither Dr. Gilbert nor Mr. Warington alluded to the point which had been raised as to the possibility of the Rothamsted soil having the nitrifying principle in excess, as on it seems to turn the pivot of the entire inquiry.

The following extracts from Professor Way's writings, to be found in Vols. 11 and 13 of the "Royal Agricultural Society's Journal" show plainly enough what his opinions were. He says:—

It has been shown that ordinary soils possess the power of separating from solution and retaining for the purposes of vegetation the bases of the different alkaline salts and certain animal and vegetable substances, and that this power extends to all those substances to which we attach the most value as manure.

In Vol. 13 of the "Royal Journal" the same view is still more fully enlarged upon as follows:—

It has long been known that soils acquire fertility by exposure to the influences of the atmosphere—hence one of the uses of fallows. It has also been

generally understood that clay possesses a power of absorbing ammonia from the air, but only through the influence of rain or dews to bring down the volatile carbonate. This latter condition, however, is not at all necessary. I find that clay is so greedy of ammonia that, if air charged with carbonate of ammonia, so as to be highly pungent, is passed through a tube filled with small fragments of dry clay, every particle of the gas is arrested. In the same way, if into a bottle filled with air similarly impregnated a little dry soil is thrown, and the bottle is then shaken once or twice, all ammoniacal smell is destroyed. The double silicate of alumina and lime is in these cases the cause of the absorption.

While the principle of ready absorption is not disputed by Mr. Lawes, Dr. Gilbert, and Mr. Warington, that of retention is entirely disallowed; the theory of these gentlemen, as founded on their experiments at Rothamsted, being that ammonia, however powerfully grasped by the silicates, is extremely liable to be again washed away by being converted into nitric acid by the nitrifying plant, the action of which, under favourable circumstances of heat and aeration, they consider to be very great. Even if this theory be admitted, the question arises, as Mr. Darby put it at the meeting, "Is it no possible that the land at Rothamsted may have this nitrifying ferment in a state of more active working than the generality of soils?"

A considerable portion of Mr. Warington's lecture was devoted to the consideration whether India might not be made an extensive nitrate-producing country, owing to its high range of temperature being favourable to the working of this nitrifying principle. It was very conclusively pointed out by him that nitrification proceeds in English soils far more actively in summer than in winter; and also that active operation only proceeds when the soil is sufficiently aerified. The subjoined extract from Mr. Lawes's pamphlet on "Fertility" also teaches very plainly that, to proceed actively in the soil, nitrification requires certain mineral constituents to be present in sufficient force. Mr. Lawes says:—

A short time ago Schlösing proved that nitrification was due to the action of a minute organism which abounds in our soils. Under favourable conditions of temperature and moisture, nitric acid is produced with great rapidity. It has been proved, in regard to the yeast plant (which converts sugar into alcohol and carbonic acid), that, like our ordinary crops, its growth depends upon a supply of mineral food. We know the nitrifying plant cannot carry on its work unless it is furnished with alkaline substances to to neutralise the nitric acid formed. If, as may be the case, it requires alkalies and phosphates, we can explain why it is that the water passing through peaty soils does not contain nitric acid.

From all this it not only seems possible, but very probable, that this principle of nitrifying would not proceed so actively in a great many soils as it has been found to do in that of Rothamsted. At any rate, before conclusions so very startling as those propounded by Mr. Lawes, Dr. Gilbert, and Mr. Warington are accepted as forming the new gospel of chemistry, they ought to be confirmed by careful analysis of a dozen or more different soils, especially as they seem to overturn at one fell sweep all the early teachings of the sages.

The solution of the problem appears to be of the very utmost importance to agriculture, because, if this nitrifying principle have only gentle and slow action—while it may prove a blessing by preparing plant food for crops—in the form brought to light by the Rothamsted experiments it appears as a devastating angel indeed, slumbering beneath the surface of the soil, only to be awakened by the very agencies which the farmer employs in the vain endeavour to increase the earth's fertility, inasmuch as the treasures of earth and air would only be brought together by tillage to be a prey for the spoiler's hand. Even the magicians who have conjured up this phantom seem half afraid of it; for Dr. Gilbert, speaking at the meeting of the Society of Arts, assured those present that ammonia furnished to the soil in a vegetable form would not be liable to the same risk of loss. But although this may relieve anxiety slightly in respect to farmyard dung, I fear that no similar exemption could candidly be made by him for the large amount of ammonia which must be contained in the urine of sheep that, before consuming green crops, have been highly fed on oilcake.

A case for more inquiry is certainly then disclosed, the necessity of which appears all the more urgent because the natural inferences to be drawn from the Rothamsted theory, as it now stands, cannot be considered at all favourable to farming enterprise, but as rather calculated to deter everybody from undertaking the task of exciting in the soil a fertility which, in addition to the labour and expense required to produce it, is stated to be extremely liable at any time to be washed out of the soil into the drains.

AGRICOLA.

[We quite agree with our correspondent as to the desirability of carrying out experiments of the same character on different soils; but, until this is done, we see no reason for concluding that there is anything abnormal in the soil hitherto experimented on. No doubt it is easy to answer in the affirmative the question as to the *possibility* of the Rothamsted soil having a more powerful nitrifying action than soils in general; but the same answer could equally well be given were the question put as to the possibility of the action being *less* instead of more. In either direction there is a possibility, but the probability seems no greater on the one hand than on the other; and little harm can be done by assuming the Rothamsted soil to be of an ordinary character, until there is evidence to prove the contrary. As to Professor Way's writings, we do not look on them as so diametrically opposed to Mr. Warington's statements as our correspondent considers them to be; but, even if they were, it is no reproach to Professor Way to say that he could not know twenty years ago what has been subsequently discovered. Professor Way's views, as above quoted, merely indicate that nitrogen would not escape through the soil in the form of ammonia; but he also showed that, although the amount of nitrogen passing off in the form of ammonia is trifling, perfectly oxidised nitrogen (nitric acid) is carried off in large quantities in drainage waters. Mr. Warington's investigations go to show how readily ammonia is converted into nitric acid while in the soil; and in estimating the actual amount of nitric acid carried off by the water, he has had recourse to a method of analysis which was not elaborated till long after Professor Way wrote. But the discovery of the fact that, under certain circumstances, nitric acid is carried off more rapidly than has hitherto been supposed, need not lead us to consider the action of the soil as that of a "devastating angel." Mr. Warington showed, in the lecture we published a fortnight ago—(1) that nitrates were being continually produced; (2) that they were easily lost; and (3) that that loss may be prevented by a crop. No more nitrates are likely to be carried off in the future than have been carried off in the past, because it is ascertained that the loss is much greater under some conditions than under others. On the contrary, by availing ourselves of the knowledge now gained, and learning how and when to apply manures with the greatest advantage, we may hope to save much of the waste that has hitherto gone on undetected.—ED.]—*Field.*

TREE PRUNING.

(Translated from the French of A. des Cars, by Charles S. Sargent, Professor of Arboriculture in Harvard College, U. S.)

Aim and Method of Pruning.—The object of pruning, economically considered, is to make it possible to raise on a given surface, say on one hundred acres of sprout land, the greatest number of full-grown trees, and to make them attain the greatest value in the shortest time without injury to the young trees beneath them. This may be accomplished by increasing the vigour of the reserve trees and by lengthening, without diminishing in diameter, their trunks. Treated in this manner the reserve trees do not interfere with the circulation of air and light necessary to the development of the undergrowth; and many serious accidents caused to trees by wind, frost, and snow breaking the larger branches may be avoided by keeping their heads symmetrical and upright.

The perfect forest tree has a straight, single trunk, without protuberances or wounds, and carrying up the same diameter to the first branches, which should be placed at a distance from the ground equal to one-third or one-half of the total height of the tree. The head should be rounded, regular, and set upright on the trunk. The wood, owing to the healthy growth of the tree, is straight-grained, compact, and suitable for construction. Such trees have a high value; and, in order to grow them, a method of pruning is adopted similar to that practised by gardeners in forming pyramidal fruit trees, with the difference, however, that the gardener favours the development of the lower branches, which are necessary for his purpose, while the aim of the forester is to increase foliage at the top of the tree by diminishing the vigour of the lower branches; and to obtain by successive suppressions of branches the necessary length of trunk.

There are two distinct operations in pruning: the removal of some branches, the shortening of others. The shape of a tree must depend somewhat, of course, upon its age, the nature of its surroundings, and the character of the soil, &c. Where pruning is not practised, the reserve trees approach the proper form in proportion to the length of time the coppice beneath them is allowed to grow. In forests, where thirty or more years are allowed to elapse between the cuttings, the undergrowth serves to prune the permanent trees by checking the development of their lower branches, and thus determining the height of their trunks. Sprout land is, however, often cut over every ten years; and this practice prevents the production of fine trees by permitting the growth of their lower branches. These, of course, interfere with the growth of the reserve trees themselves as well as with the young trees between them. Judicious pruning can obviate this difficulty.

Classification of Forest Trees according to Age.—The technical names by which reserve trees are known vary in different regions. For our purpose it will be best to divide the life of a forest tree into four principal periods, designated as follows:—

1. Young, up to about forty years.
2. Middle-aged, from forty to eighty years.
3. Old, from eighty to one hundred and fifty years.
4. Very old trees, whose number is rapidly diminishing may be called veterans.*

* The technical terms employed in France to designate trees of the four classes into which forest trees are generally divided, *Baliveau, Moderne, Ancien, and Vieilles écorces*, have no equivalent as yet, and are not well translated into English. The term "Baliveau" is also sometimes applied to reserve trees of any age left after the first cutting off of a plantation, and such trees are then called "Modernes," or "Anciens," according as they have been allowed to remain after a second or third cutting of the coppice.—C. S. S.

These divisions are not, of course, absolute, as it is often difficult to determine, even approximately, the age of a standing tree; and the forester must use considerable judgment in the application of the following rules:—

1. The head of the young tree should be egg-shaped or elongated oval, and well balanced on the trunk, which should not exceed a third of the entire height of the tree. The lower branches should be sufficiently shortened to check their excessive growth at the expense of the leader, without, however, being so reduced as to impair the vigour of growth of the tree.

2. The head of the middle-aged tree should form an oval less elongated than that necessary for trees of the first class. The height of the trunk should equal one-third to two-fifths of the height of the tree.

3. The head of the old tree should be gradually rounded in outline; the trunk may, in some cases, be made to reach a height equal to half the height of the tree, which has now probably ceased to grow upwards.

4. *Veterans.*—Trees classed as veterans have generally ceased to increase in size. They gradually become flat-headed, and spread out, without, however, greatly injuring the adjoining coppices and plantations destined to take their places.

The proper method of pruning trees in each of these four divisions will be considered hereafter.

It is well to remember that the forms recommended are those nature gives the most perfect and most beautiful trees; although it is the most economic and not the picturesque aspect of trees which is here under consideration.

Tools used in Pruning.—The most convenient tool for pruning is a straight-bladed cleaving knife. Success in all operations of pruning depends on the neatness of the cut, and this cannot be attained with the common billhook used in many parts of France. The best tool for the purpose is one which has been used for many years in Holland, and which has lately been improved by de Courval. It weighs from 2 lb. 12 oz. to 3 lb. 6 oz., or more, according to the strength of the workman. The blade is reinforced in the middle to increase its strength and concentrate the weight. In the north of France this tool is generally hung to an iron hook attached to a leather strap buckled round the workman's waist, who is thus left perfectly free in his movements.

In pruning tall trees, or trees otherwise difficult to climb, the leather belt may with advantage be passed over the shoulder, thus bringing the pruning knife under the arm in a position from which it cannot easily be dislodged in climbing. To ensure greater safety in climbing tall trees, a stout cord attached to the workman's man's waist may be fastened round the trunk in such a manner as to prevent, in case of accident, a dangerous fall. A hatchet is useful, and facilitates the operation of pruning; it may be used with one or both hands, and serves to lop off large branches, protuberances on the trunk, or the dead stumps of branches, which from their hardness would soon dull the edge of the best pruning knife. A saw, too, is very useful in cutting large branches, but it requires so much practice to use this tool skilfully that it cannot be generally recommended.

Ladders.—Each labourer should be equipped with a light ladder, proportionate to the height of the tree on which he is to operate, and broader at the base than at the top. De Courval recommends that the feet of ladders intended for this purpose should be pointed to prevent them from slipping. This is a good plan, although hardly sufficient to prevent accident, and the top of the ladder should be fastened with a strong rope to the trunk of the tree to prevent it from being thrown down by falling branches.

Hooks or Spurs.—Except in very exceptional cases, or where very large trees are to be operated on, the climbing spurs sometimes used by professional pruners should not be allowed. These men, paid according to the number of trees operated on or the quantity of wood

cut, have no idea in pruning beyond cutting the largest amount of wood in the shortest time. Climbing spurs should never be used by good workmen even, in pruning young trees, whose bark is not sufficiently thick to resist the wounds caused by the sharp iron teeth of this tool. Wounds made in this way encourage the growth of injurious side shoots on the trunk, and leave defects in the wood which never disappear, and diminish its value.

The future value of a tree depends upon the manner in which the operation of pruning has been performed; and the persons to whom this work is entrusted should fully understand its importance. Unskilful or injudicious pruning may completely ruin a tree, and the difficulty of obtaining labour capable of doing such work intelligently causes, no doubt, many arboriculturists to completely neglect pruning of every kind.

The Dendroscope.—The tree requiring pruning should be carefully studied from the ground, that the operator may be able to judge intelligently which branches should be removed or shortened in order to reduce it to the desired shape. This may at first seem difficult to beginners in the art of pruning; and a dendroscope, the name suggested for a simple little contrivance, may be here used with advantage. A dendroscope may be made from a piece of thin board or cardboard (a playing-card answers the purpose), in which a hole of the shape it is desired to reduce the tree to has been cut. Across the middle of the hole, from top to bottom, a piece of fine wire is stretched to serve as a guide to the eye.

Holding the dendroscope at the level of the eye, with the wire opposite the centre of the trunk of the tree to be studied, the operator approaches the tree until the bottom of the cut falls on the trunk at the ground line. It is easy to see at a glance with the aid of this contrivance what operations should be performed in order to reduce the tree to the desired shape.

Remembering that under ordinary circumstances a vigorous, handsome tree must have a straight, vertical trunk and an evenly-balanced head, the first object of pruning should be to produce these conditions. The head, as has already been explained, should be oval in form; the height of this, however, must depend on the size of the trunk and the age of the tree when first subjected to the operations of pruning.

Selection of the Leader.—The branch most nearly perpendicular on the trunk of the tree should be selected to form the leader; and it may be stated as an absolute rule that *whenever a branch near the top of the tree stands vertically on the trunk, or even on any part of the trunk, it should be preserved for the leader.*

And it is wrong to suppose that only the original leader can be used. Its place may be often supplied by one of the lateral branches even: and by shortening the other branches to stimulate the growth of the new leader, the tree will, in a few years, straighten up in a manner which will appear astonishing to persons unfamiliar with the results which may be obtained from a sensible system of pruning.

If none of the branches near the top of the tree naturally approach a vertical position, two or three or several branches should be preserved to form a compact head. If the tree so treated is young, it is desirable, if possible, to establish the fork at a distance from the ground equal to at least one-third of the height which the tree may be expected to attain at maturity.

Shortening Main Branches.—Starting from the top of the tree, where the operation of pruning should always begin, the leader is first formed with the branch selected for this purpose; the head is made with a single leader: or, in case of necessity with several leaders. The principal branches, if too long, should then be shortened, especially those inclined to assume a vertical position or to grow with too great vigour at the expense of the leader; such branches are called gourmands. It will be seen that the right point at which to shorten these vertical branches is the point where they begin to assume an upright growth.

In shortening branches, the cut should, if possible, be made above the point of development of one or several secondary ascending branches; these in turn should also be cut just above one of their secondary branches. In this way the direction of the main branch may be entirely changed, and its disproportionate vigour checked to the benefit of the leader and the whole tree.

Sap Lifters.—The name sap lifter *(Branche d'appel)* may, for want of a better term, be given to the branch or branches retained at the end of the shortened main branch. The name indicates the object for which such branches are left; namely, to attract and elaborate, by means of their leaves, a sufficient flow of sap to ensure the growth of the branch. Sometimes the main branches are so long that it is impossible for the operator to reach the ends where the sap-lifting branchlets should, of course, be left. In the case of the oak, such branches, except for the appearance of the tree, are of little importance; and provided the main branch retained is of a certain length (ten or twelve feet), and if it is large and on a large healthy tree, a sufficient number of new shoots to ensure vigorous growth will soon appear. With the beech, however, and some other trees which do not develop shoots from dormant buds as freely as the oak, it is necessary to cut the branch just above the forking of another branch or branchlet large enough to attract sufficient sap to ensure a healthy growth.

Double or Forking Branches.—In the case of a double branch, or of a branch forking close to the trunk of the tree, one of these branches should always be removed, that the base of the branch may not become disproportionately large. If, however, such double branches are objectionable near the trunk of the tree, they are of great importance at the extremities of main branches; and whenever it is possible branches should be shortened in such a manner as to secure forking branchlets at their ends. These give to the tree a more natural appearance, and by dividing the flow of sap prevent the growth of too vigorous shoots, which might in time develop into supplementary leaders, to the injury of the tree. For this reason it is necessary to remove all branches or branchlets assuming a vertical growth or inserted on the upper side of a shortened branch, in order to check the tendency of such branches to grow too vigorously at the expense of the leader.

Although essential in pruning young trees, this is less important in the case of older trees with large full heads, which in themselves have a tendency to check an unnaturally strong growth of any individual branch; and in operating on old trees the preservation of vigour in the shortened branch is the principal object to be attained. It is almost unnecessary to add that only main branches directed towards the outside of the tree should be preserved, and that branches which from any cause have turned back towards the trunk should be headed in, as well as branches with too great a tendency to droop unnaturally; generally, it will only be necessary to shorten such branches to induce them to reassume a natural direction of growth.

When several branches have been developed from one node, forming what botanists call a whorl, they should not all be cut away at the same time, lest the circulation of sap be checked by the destruction of bark (and consequently of cambium layer) over too large a surface.

All dead and dying wood should be removed by the workmen in descending the tree; lichens, and other parasites which interfere with the growth of young trees, should be knocked off with the back of the pruning knife; and the mistletoe, the most destructive of all parasites to tree life, should be carefully removed by cutting off the branch bearing it.

The necessity of commencing the operation of pruning at the top of the tree must be insisted on; in no other way can the form proper to the tree be estab-

lished or the safety of the operator preserved. The disregard of this rule was followed not long ago by what might have been a severe accident. An excellent workman was about finishing the pruning of a beech tree; two long, slender branches remained to be operated on. He cut the lower of the two branches first; the twigs on the ends of the branches had become interlocked, and the branch B, in falling, pulled down the branch A. This broke under the weight of the first, and, striking the operator on the head, inflicted a severe wound, causing his fall to the ground, a distance of twenty or thirty feet.

The Amputation of Large Branches.—Many of the lower branches previously shortened must afterwards be removed, from time to time, until the necessary height of trunk has been attained. The number of branches to be removed must, of course, depend on the height of the tree, the nature of the soil in which it grows, and its age when first operated on. Great caution should be observed in amputating large branches; small branches can, of course, be lopped off at any time without danger to the tree. We agree with de Conrval that at least three medium-sized branches may be safely removed from a tree in one year, although if the branches are very large, not more than one, or perhaps two, should be cut at one time. It is always desirable, however not to unnecessarily increase by the removal of living branches the wounds left on the trunk by the cutting off of dead branches or other excrescences. Whenever it is necessary to amputate a large or long branch, it should be cut first in such a manner as to leave a stump two or three feet long before the final operation of cutting it close to the trunk is undertaken. In this way the danger of tearing away by the weight of the falling branch portions of the bark of the trunk may be avoided. This will prevent, too, the serious accidents which often occur when a large branch is cut at first close to the trunk, when the end striking the ground may cause the butt to fly up and throw down the workman. It is an indispensable condition of the prompt healing over and perfect circulation of sap that all wounds should be evenly cut and shaped as nearly as possible to the trunk of the tree. In order to secure this condition, the operation of amputating a branch should be commenced by making a notch on its lower side. This notch should reach the middle of the branch; a second notch should then be made on the upper side of the branch, but further from the trunk of the tree than the cut. By adopting this method all danger, too, of injury to the trunk from the weight of the falling branch tearing away the bark will be avoided.

The operation of amputating a branch will not be complete, whatever method is employed, until the wound is made perfectly smooth. The workman may do this with his hatchet, used as a plane, the handle being held in one hand and the point of the blade in the other.

Use of Coal Tar in Dressing Wounds.—All wounds made on the tree in pruning should be covered with a coat of coal tar applied with an ordinary painter's brush.

The importance of observing the directions which have been given, however trivial or unimportant they may seem, will be apparent when it is understood that the entire success of the operation of pruning, and of the future production of timber, depends on the proper application of these rules.

It should always be borne in mind that a cut perfectly smooth, and as closely following the line of the trunk as circumstances will permit, is soon re-covered with healthy straight-grained wood. In this connection it is well to quote from de Conrval, who speaks with the authority of experience, and who has shown with many varieties of trees the correctness of his statements. "A casual examination," he says, "will show that between the surface, which has been cut smooth and treated with coal tar, and the new tissues which soon cover it, there is only the thinnest crack or fissure analogous to the natural cracks or openings which always appear in wood in seasoning, and which, as is well known, do not diminish its strength, elasticity, or value for all industrial purposes."

In the preceding pages the general rules which should be followed in pruning forest trees have been given; the special methods applicable to each of the four classes in which trees have been placed according to their age will now be briefly explained.—*Journal of Forestry.*

Correspondence.

To the Editor of the Tropical Agriculturist.

ORANGE CULTIVATION.

Coonoor, Madras, April 15th, 1882.

DEAR SIR,—Information regarding the cultivation of oranges would be valued by more than one planter here: the sorts to grow, the way to grow them, with the probable profits if any. Trusting you may be able to find space in your paper for improving our education on this subject.—I am, yours faithfully,

W. RHODES JAMES.

[We copy the following from the *Gardeners' Dictionary*, edited by G. W. Johnson:—

CI'TRUS. Orange-tree. (Derivation of doubtful origin; supposed to refer to *Citron*, a town in Judæa. Nat. ord., *Citronworts* [Aurantiaceæ], Linn., 18. *Polyadelphia 2-Polyandria.*)

Greenhouse evergreen trees.

Common Orange (C. aurantia'eum).—The following are esteemed varieties:—the China, Blood-red, Sweet-skinned, the Ribbed, Pear-shaped, Tiny-fruited, Fingered, St. Michael's, and Mandarin. The Mandarin and St. Michael's, are far superior to the rest for cultivation. The Mandarin is cultivated extensively at Malta, although originally from China; it has a thin rind, and is of very superior flavour. The St. Michael's is also a small orange, but the skin is of a pale yellow; the rind, also, very thin, and the pulp remarkably sweet. The fruit is generally without seed, and the tree is a great bearer.

The Lime (C. lime'tta) approaches the lemon; but the juice is flat, and somewhat bitter.

The Shaddock (C. decuma'na) has a large and round fruit; skin yellow, with a white, spongy rind; the pulp sweet and juicy. This has been successfully cultivated, in Devonshire, on the open walls, with protection in winter, but no artificial heat.

The Lemon (C. limo'num).—The Continental growers are content to raise these from seed; hence the great difference in quality of the imported fruit.

The Citron (C. me'dica) has a rind thick, spongy, and very fragrant; pulp, sub-acid.

Propagation.—All the kinds will propagate freely by *cuttings*, either of the young shoots, or of those riper in character. They are prepared in the usual way, and inserted in pots of sand. A close frame, with a bottom-heat of 75°, is necessary, and they must be plunged. They may be made at any period, excepting whilst the plants are growing. Some cultivators put out long, straight pieces of the Citron (which is easiest to propagate), of two or three years' growth; and, as soon as they are rooted, they graft them.

Layers root with facility, but do not make such fine plants.

Grafting.—There are various ways of performing this operation, dependent much on the size and character of the stock. Some graft the young seedlings which were sown in early spring: these, by bottom-heat and high culture, are rendered fit for this operation in about four or five months. No clay is used in this delicate operation, but a little fine moss. Some cut off the head of the stock and crown-graft; others attach the graft to the growing shoot, as in ordinary whip-grafting. *Budding* is also practised by some cultivators.

Inarching has sometimes been practised by inarching several plants on one large stock, in order to form a head speedily.

Stocks.—The Citron has been mostly preferred; the Shaddock, however, makes a robust stock. M'Intosh seems to recommend sowing any ordinary seeds—from such fruit, indeed, as have rotted in the warehouses, from which he has had complete success.

Seeds.—The mode of rearing them thus is simple enough. A light, rich soil and a lively bottom-heat, with a somewhat close atmosphere, will produce plants eighteen inches high in a few months.

Soil and Culture.—All the family love a generous soil. One half a free, yet rich loam, and the other half composed of leaf-mould, old cow-manure, and sandy heath-soil, will grow them in high perfection, adding a little sand and some charred materials. Care must be taken to use the turfy loam in lumps, and to drain well; indeed, all the materials should be somewhat coarse. They require liberal watering; and it must, when given, penetrate the whole mass of soil. They enjoy liquid-manure occasionally. They are not only grown in pots or tubs, but planted out as trees, and against walls and trellises; and they are equally adapted for all these modes of culture. Span-roofed houses would be highly eligible for them as standards; and the sides and ends, being portable, might be removed in summer. The Citron family are impatient of intense sunshine, being, for the most part, natives of woods. A slight amount of shading, therefore, becomes occasionally necessary. The temperature during winter—especially in houses with opaque roofs—must be very moderate: 48° to 50°, by means of fire-heat, is quite sufficient. As light increases with a returning spring, the thermometer may be permitted to advance a little. In light houses, a thermometer of 50° to 55° will do no injury. Here, however, shading will, at times, be requisite.

Fruit, Uses, &c.—Besides forming, in its natural state, one of the adjuncts of the modern dessert, these fruits are used in a variety of forms, both in confectionery, sweetmeats, and liqueurs. Thus, the *Seville*, Bizarade, or Bitter Orange, having a very bitter rind, is used for marmalade, bitter tinctures, candied peel, and for flavouring curacoa. The Bizarades are the kinds used principally for the production of cut blossoms by the French gardeners. The *Bergamot* has a pear-like fragrance: from this the perfumer obtains his bergamot essences. The *Lime* is used in flavouring punch and confectionery. The *Shaddock* has a cooling and refreshing juice; and the fruit is a splendid addition, in appearance, to the dessert. The *Lemon* is too well known to need comment. The *Citron* is used for sweetmeats, lemonade, and to flavour negus and punch.

Diseases.—We are not aware of anything which may be strictly termed a disease of this genus. A *black fungus* is frequently found on the leaf, having the appearance of soot, and perhaps arguing a corrupt atmosphere, through a too close confinement. This must be cleaned away, by a sponge, with warm water.

Insects.—The *aphis* and the *scale* (coccus) are amongst its principal enemies. The former may at all times be readily destroyed by fumigation; the latter may be rubbed off by means of sponge bound on a stick, frequently dipping the sponge in a liquor consisting of two ounces of soft soap beat up in a gallon of water.—ED.]

Pricking off.—This is a term used by gardeners for the process of transplanting small seedlings as soon as they are fit to handle, and replanting them closely together, preparatory to being planted in pot or in the open ground. It is distinguished from planting proper, inasmuch as the "pricking off" process is always preparatory to the final planting. For example, when tomatoes come up thickly in the seed bed, they must be pricked off at a distance of an inch or so apart in a hot-bed, again to be planted, either wider or in the open air. If this is not done, as soon as they are fit to handle, the plants will spindle and get weak, and often will die off altogether from damping.

Propagation by Seeds.—The most natural way of increasing plants is by seeds; and, whenever it is practicable to do so, it is preferable to all others, so that, in our own practice, any plant of which we can procure the seed, we rarely increase in any other way, unless, in cases where particular varieties are wanted that we know will not reproduce themselves from seed, so as to be certain of color or form; but in all cases where seed taken from a variety or species will reproduce itself exactly, or in cases where a general variety is wanted, the propagation by seed is invariably practiced. As propagation by seed refers more usually to ornamental plants cultivated under glass, we will briefly relate our own practice, which we have greatly improved during the past few years, and in which we have attained almost unfailing satisfactory results. We have found that seeds sown in shallow boxes, from one and a half to two inches deep, can be given a far more uniform degree of moisture than when sown in earthen seed pans made specially for that purpose. Those boxes are made from the ordinary soap-box, from four to five being made from each, with the bottom boards so put on as to allow free escape of moisture, though of course, not so wide apart as to allow the soil to wash through. These boxes are filled with finely sifted soil, such as has been run through a sieve fine as mosquito netting. This surface is then made perfectly level and smooth, and the seeds sown on it as evenly as possible, and in thickness corresponding to the variety sowed, though it must be here remembered that "in union there is strength" and that, if sown too thin, weak seeds may fail to press up the soil, if isolated too much. After the seeds are sown, and before they are covered, they are pressed down by a smooth board into the soil, so that the surface is again smooth and level.

The seed box is now ready for its covering. For the past year we have used finely-sifted moss (sphagnum) exclusively for covering. To prepare this it is rubbed through a mosquito wire sieve when dry and sifted over the seed only thick enough to cover it, usually about one-sixteenth part of an inch. In the absence of moss, dry refuse hops, coconut fiber, or leaves will answer, prepared in the same manner, the great object being to use a material light in weight, having non-conducting properties, and that will thus hold the moisture uniformly. Of all these, we think moss the best, and now use nothing else, as its sponge-like character keeps just the right degree of moisture wanted. These seed boxes should be placed in the open sunlight, in the windows of the dwelling-groom, in the hotbed or greenhouse, and never shaded, in a temperature running from 55 degrees to 65 degrees at night, with 10 degrees during the day; and, if a proper degree of moisture is applied, say a light sprinkling once a week, if there is life in the seed, germination is certain. As soon as the seeds have grown so as to attain the first true leaves (that is the first leaves that show after the seed-leaves) they must be "pricked off" (which see) carefully in soft, light soil, similar to that used for the seeds, at from one to two inches apart, according to the kind. This will not only prevent them from damping off, as many of them are very apt to do, but they will be much stronger and suffer less when put into flower pots or replanted in the open ground. We prefer to replant the seedlings in the shallow boxes already described. And here we again find that, if the soil is mixed with half its bulk of sifted sphagnum, we get a far better development of fibrous roots. They are more portable thus than if planted again in the soil of the hotbed, or bench of the greenhouse, though, of course, after planting in the boxes, these are put again in the hotbed or greenhouse. After the seedlings have been planted in these boxes, lightly water them and shade for two or three days.

To such as have not the convenience of a hotbed or greenhouse, vegetable or flower seeds may be sown in the shallow boxes above mentioned, and placed in the window of a south or east room, where the thermometer does not average less than 70 degrees. Success would be more complete, however, if panes of glass were placed over the seeds, resting on the edge of the box an inch or so from the soil. This would prevent evaporation, and render watering less necessary.

Propagation of Plants by Cuttings.—As now understood, this is a simple matter. Formerly no operation in horticulture was more befogged by ignorant pretenders, who, in writing or speaking on the subject, warped the operation with troublesome conditions as to discourage not only amateurs in horticulture but inexperienced professional gardeners as well.

One of the first necessary conditions in the propagation of plants by cuttings is that the plant from which the cutting or slip is taken must be in vigorous health. If weak or tainted by disease, failure is almost certain to result. If, for example, we wish to root cuttings of greenhouse or bedding plants, such as *Bouvardias*, *Chrysanthemums*, *Fuchsias*, *Geraniums*, *Heliotropes*, *Salvias*, *Verbenas*, etc., one of the best guides to the *proper condition* is when the cutting breaks or snaps clean off instead of bending or kneeing; if it snaps off so as to break, then it is in the condition to root freely; if it bends, it is too old, and, though it will root, it will root much slower, and make a weaker plant than the slip that snaps off on being bent. With exceptions so few, and those of so little importance that it is hardly worth while to allude to them, cuttings of all kinds root freely from slips taken from the *young wood*, that is, the succulent growth, before it gets hardened, and when in the condition indicated by the "snapping test," as it is called. We believe we were the first to call attention to this valuable test of the condition of the cutting (snapping) in our work, "Practical Floriculture," first published in 1868. A very general idea is current that cuttings must be cut at or below an eye or joint. The practice of this system leads undoubtedly to many cases of failure; not that the cutting at or below a joint either hinders or assists the formation of roots; but from the fact that, when a slip is cut at a joint, the shoot often has become too hard at that point, while half an inch higher up or *above* the joint the proper condition will be found. We know that it will root even when in the too hard condition, but the roots emitted will be hard and slender, and, as a consequence, will not be likely to make a plant of the same vigor as that made from the cutting in the proper state; besides, as the hard cutting takes double the time to root, its chances of damping off from unfavorable atmospheric conditions are thus increased. With these instructions for the proper state of the cutting, we now proceed to describe the medium wherein it is to be placed, and the conditions of temperature, moisture, etc. If these are strictly followed, failure is an impossibility; for the laws governing the root of a slip aas certain as those governing the germination of a seed. In our own practice, when these conditions are strictly followed, failure is unknown.

The most proper condition of temperature to root cuttings of the great majority of greenhouse and bedding plants is 65 degrees of bottom heat, indicated by a thermometer plunged in the sand of the bench, and an atmospheric temperature of 15 degrees less. A range of 10 degrees may be allowed, that is, 5 degrees lower or 5 degrees higher, but the nearer the heat of the sand can be kept to 65 degrees, and that of the rest of the house to 50 degrees, the more perfect the success will be.

Sand is the best medium in which to place cuttings; color or texture is of no special importance. What we use is the ordinary sand used by builders; this is laid on the hotbed or bench of the greenhouse to the depth of about three inches and firmly packed down. When "bottom heat" is wanted, the flue or pipes under the bench of the greenhouse are boarded in, so that the heat strikes the bottom of the bench, thus raising the temperature in the sand.

From the time the cuttings are inserted in the sand until they are rooted, they should never be allowed to get dry: in fact, our practice is to keep the sand soaked with water, the cutting bench being watered copiously every morning, and often, when the atmosphere is dry, again in the evening. Kept thus saturated, there is less chance of the cutting getting wilted, either by heat from the sun or from fire heat; for, if a cutting once gets wilted, its juices are expended, and it becomes in the condition of a hard cutting, in the condition in which, when bent, it will not snap nor break, which has already been described. To avoid this wilting or flagging of the cutting, every means that will suggest itself to the propagator is to be used. Our practice is to shade and ventilate in the propagating house or hotbed just as soon in the forenoon as the action of the sun's rays on the glass raises the temperature of the house to 65 degrees or 70 degrees. This practice of ventilating the propagating house or hotbed is, we are aware, not in very common use; many contending that the place where the propagating is done should at all times be kept close. We have tried both methods long enough and extensively enough to satisfy us beyond all question, that ventilating and propagating at a low temperature is capable of producing a larger number of plants during the season than at a high temperature and in a close atmosphere. There need be no failures, and it has the important advantage of producing *healthy* stock, which the close or high temperature system would fail to do in the case of many plants. We have often heard propagators boasting of rooting cuttings in five days. We are well aware that this may be done, but we are also aware that it is often done in damp and cloudy weather at the risk of the whole crop, and it must be done at a high temperature, which at all times causes the plants to draw up slender, and thus impairs their vigor.

Permitting a moderate circulation of air in the propagating house tends to prevent the germination of that spider-web-like substance, which, for want of a better term, is known among gardeners as the "fungus of the cutting bench." Everyone who has had any experience in propagating knows the baneful effects of this: how that, in one night, it will often sweep off thousands of cuttings that a few hours before were in healthful vigor. But this dangerous enemy of the propagator requires, like vegetation of higher grades, conditions suitable to its development, which evidently are a calm atmosphere and a temperature above 55 or 60 degrees. Hence, to avoid this pest, we make every effort, by shading, airing, and regulation of fire heat, to keep the atmosphere of the house so that it shall not exceed 60 degrees. This, of course, is not practicable when the outside temperature in the shade is above 60 degrees; but the temperature can be reduced considerably by dashing water on the pathways and other parts of the house. It is rarely, however, that the outside temperature ever exceeds 60 degrees in the shade for any length of time in the district of New York before the middle of May, and all propagating had better be finished previous to that time, unless of tropical plants. In the fall months, about the middle of September, operations in propagating may again begin.

The temperature is prevented from rising in the house in various ways, some using canvas, or bast-matting, or painting the glass with lime or whitewash. We find the best and most convenient shading to be that formed by flexible screens made of common lath, planed and attached together like Venetian blinds, the laths being an inch or so apart; these can be quickly rolled or unrolled, and give an ever-varying modified shape, sufficiently cooling to the house, yet not darkening the cutting enough to impair its vigor. These are not unrolled in the morning until the temperature inside indicates it to be necessary, and are rolled up in the afternoon as soon as the sun ceases to shine on the glass, for it is of the utmost importance that the cuttings receive as much light as they will bear without becoming wilted. The time required by cuttings to root varies from eight to twenty days, according to the variety, condition of the cutting, and temperature. Verbenas, Fuchsias, or Heliotropes, put in in proper condition, and kept without ever being allowed to wilt, will root, in an average bottom heat of 65 degrees, in eight days, while roses, pelargoniums, or petunias, will take at least double that time under the same conditions.

It is best to pot off the cuttings at once when rooted, no matter how small the roots may be; half an inch is a much better length for them to be when potted than two inches, and the operation is much quicker performed when the roots are short than when long. But the main evils of delaying the potting off of cuttings are that, when left too long, the cuttings grow up weak and spindling, the roots become hard, and do not take as quickly to the pot. The same care is required in shading and watering after potting, nearly, as in the cutting bench; for no matter how care-

fully taken up, in the operation of potting the delicate roots are nearly as liable to wilt as the unrooted cuttings. Cuttings should always be placed in small pots, the best size being from two to two and a half inches wide and deep; if placed in larger pots the soil dries out too slowly, and the tender root, imbedded too long in a mass of wet soil, rots and the plant dies. Though we generally prefer soil to be unsifted in potting large plants yet for newly potted cuttings it is better to be sifted fine, not only that it is more congenial thus to the young roots, but also that the operation is quicker done with finely-sifted soil. After potting, the cuttings are placed on benches covered with an inch or so of sand, watered freely with a fine rose watering-pot, and shaded for four or five days; by that time they will have begun to root, when no further shading is necessary. These methods of propagating by cuttings are such as are now practised by commercial florists, but for amateurs in horticulture, or gardeners who have charge of private greenhouses, there is usually no necessity for a regular propagating house, unless the requirements for plants are unusually large, as the "*Saucer System*" of propagation will answer every purpose, and it is the safest of all methods in inexperienced hands. We were, we believe, the first to introduce this system some twenty years ago, and here repeat the directions first given in one of the horticultural journals at that time. "Common saucers or plates are used to hold the sand in which the cuttings are placed. This sand is put in to the depth of an inch or so, and the cuttings inserted in it close enough to touch each other. The sand is then watered until it becomes in the condition of mud, and placed on the shelf of the greenhouse, or on the window-sill of the sitting-room or parlor, fully exposed to the sun, and never shaded. But one condition is essential to success: until the cuttings become rooted *the sand must be kept continually saturated, and kept in the condition of mud*; if once allowed to dry up, exposed to the sun as they are, the cuttings will quickly wilt, and the whole operation will be defeated. The rules previously laid down for the proper condition of the cuttings are the same in this case, and those for the temperature nearly so; although, by the saucer system, a higher temperature can be maintained without injury, as the cuttings are in reality placed in water, and will not droop at the same temperature as if the sand was kept in the regular condition of moisture maintained in the propagating bench. Still, the detached slip, until rooted, will not endure a continuation of excessive heat, so that we advise, as we do in the regular method of propagating, that the attempt should not be made to root cuttings in this way, in this latitude, in the months of June, July, or August, unless with plants of a tropical nature. When the cuttings are rooted, they should be potted in small pots, and treated carefully by shading and watering for a few days, as previously directed."

Propagation by Layering.—Although layering may be done with the ripened wood of vines or shrubs of the growth of the previous season, yet it is preferable to use the shoot of the present year in its half green state: for example, a rose or flowering shrub is pruned in the usual way in spring; by June or July it will have made strong shoots one, two or three feet in length from or near the base of the plant. Take the shoot then in the left hand (after having stripped it of its leaves for a few inches on each side of where it is to be cut), keep the fingers under the shoot, and make a clean cut on the *upper part*, an inch or so in length, and to about half the thickness of the shoot, then slightly twist the "toogue" or cut part to one side. Having opened a shallow trench, fasten the branch down with a hooked peg, and cover with earth. It is a good plan to place a flat stone over the layer to prevent the soil from drying out. This plan of cutting the shoot on the *upper* side we have never seen in illustrations showing the manner of layering, it being usually either on the side or under; but we have found in practice that it is much the safest plan, as the "tongue," when cut on the top part of the shoot, has far less chance to be broken off.

Propagation by layering in pots is the process of layering shoots or runners of plants in pots, so that, when the root forms in the pot, the plant can be detached without injury to it, as the roots are confined exclusively to the soil in the pot. Layering plants in pots can be done with roses, vines, or shrubs of any kind, with always more certainty of making a plant quicker than by the ordinary way of layering the shoot in the soil. This system of propagating strawberries has been largely practised during the past ten years in the United States, and is now a favorite method. For details, see *Strawberry*, p. 221.

Propagation by Layering in the Air.—About twenty years ago we published a method of propagating geraniums, that, we believe, originated with us, and which we called, for want of a better term, "Layering in the Air." It consists in tonguing the shoot to be used as a cutting half through with a knife, as in the ordinary layering; the shoot so treated formed granulations, or "callus," on the cut surface, and was in a condition to form roots immediately on being detached and put into the earth. A year or two ago we bethought ourselves of our long-forgotten plan of "layering in the air," but this time we improved upon the former way of doing it. Instead of tonguing the shoot to be used for a cutting, as before, it was merely snapped short off at a point where the condition of the shoot or slip would make it hang on to the plant by the merest shred of bark. Slight as this strip of bark is, it is sufficient to sustain the cutting, without any material injury from wilting, until it forms the "callus," or granulated condition, which precedes the formation of roots. The cutting, or slip may be detached in from ten to twelve days after it has been broken in the manner described, and then potted in two or three inch pots. If watered and shaded rather less than required by ordinary cuttings, it will form roots in ten or twelve days more, and not more than two per per cent. will fail. Plants of the tricolor geraniums, which all know are difficult to root under the ordinary modes of propagation, particularly in hot weather, do excellently by this plan.

The advantage of this method is not only that the slips root with far greater facility, but the injury to the stock or mother plants is far less than if the slips had been cut clean off instead of being only partly detached. Many other plants can be thus propagated with safety, notably *Begonias*, *Petunias*, *Poinsettias*, and such plants, the cuttings of which have a tendency to damp in hot weather.

CHARRED BRAN FOR PRESERVING FRUIT.—The *Scientific American* writes:—"The use of charred bran for preserving delicate fruit while on the road to market, bids fair to solve the problem which has so long perplexed our millers. Converted into charcoal, the light and slippery product of the mills ceases to be unmanageable; and it is quite likely that a large local demand for charred bran will arise in the vicinity of most mills for packing not only quickly perishable fruits like peaches, plums, and grapes, but also apples and others firmer fruits, for storage as well as for transportation." It is probable that charred bran would answer equally well for packing tea seed. The experiment would certainly be worth the trial.—*Indian Tea Gazette.*

COCOA PLANTS FOR EASTERN COLONIES.—In an official report on the subject, Mr. Prestoe, the Government Botanist at Trinidad, remarks:—"The best kinds are by no means well-known. Indeed, with the majority of growers here they are not known at all, and they never notice a difference in the character of the trees nor that of the sample of produce, except in respect of *Calabacillo*, or 'wild' cocoa, and this they very rarely eliminate. In the whole range of varieties, however, there is a difference in the value-yield of at least one to five. Under these circumstances, the value of the cocoa plants now forwarded should be regarded as of rather a botanical or scientific nature, than as an agricultural or economic one, for immediate effect, for the varieties being separated and described, as far as it is practical, to have them, there is a base for experiments, and tests as to what are their real characters, and what may be done with them in the way of improvement."—*Journal of the Society of Arts.*

THE ORIGIN OF TEA-DRINKING.

As a specimen of destructive criticism, the following article from the *North China Herald* is simply perfect. But we wish the evidently well informed writer had given us some idea of the earliest well-authenticated mention of tea by a Chinese writer. It is beyond measure strange that Marco Polo, while mentioning not only silk, sugar, and camphor, but even ginger, should have left tea utterly unnoticed. This case shews the danger of arguing from negative testimony even more than that of the non-mention of cinnamon in the sacred and historical books of Ceylon. On the negative testimony of these records, the German savants (some of them) expressed doubts as to cinnamon being indigenous to Ceylon, and a great controversy was the consequence. The sufficient explanation in this case seems to be that the Sinhalese writers had too exclusively in view the glorification of Buddhism and of the kings who favoured it and built irrigation tanks, to trouble themselves about a plant which was not used in the Buddhist services and which did not require irrigation. But Marco Polo was a traveller who professed to record all the notable things he saw in his wanderings, and for him to omit tea-drinking in China is as strange as would be a similar omission in regard to whiskey in Scotland and Ireland and beer in England, by a traveller from a foreign land, professing to note and record the manners and customs, dress and food of the people. According to the *North China Herald* the Muhammadan travellers in China who preceded Marco Polo by half-a-dozen centuries were as mysteriously silent in regard to tea as was the mediæval Christian traveller. But it seems beyond question that tea was in use by the Chinese, centuries before the Muhammadan travellers visited China. The general belief is that the plant and the value of its leaves were known so early as the fourth century of our era, while Baildon, in his recently published book on Indian tea, broaches the theory that for the introduction of the plant and a knowledge of its varieties, China is indebted to an Indian Prince who visited the celestial empire in the early years of the sixth century. The Shanghai writer might be able to speak with some authority on this point. The tone, however, in which he notices Baron Richthofen's theory of how the use of tea in correcting bad water was discovered would seem to shew that he believes tea to be indigenous to China, while the period at which its virtues became known is uncertain. We have just had experience of a neglect apparently as curious as that of Marco Polo. His editor, Col. Yule, being the author of the article "China" in the new edition of the *Encyclopædia Britannica*, we referred to that article, never doubting that under the heading "TEA" we should find embodied all that was known or surmised on the subject. But, except as an article entering into the commerce of certain provinces, tea is not mentioned in Col. Yule's account of China. We suppose Col. Yule was instructed to hold his hand because all the information available regarding tea in China would be embodied in the special article "TEA." That would explain a brief treatment of tea amongst other vegetable productions, but in Col. Yule's otherwise elaborate and valuable article on China there is absolutely no such section as "vegetable productions": they are simply mentioned, a few of them, incidentally!

The last inaccuracy concerning China which has fallen under our observation (reproduced in another column) is in itself of a very trivial nature, and is worthy of mention only as a specimen of a class. A gentleman who writes in *Once a Week* has been burrowing into antique manuscripts in the British Museum and has there discovered a paper, prepared by one Thos. Povery, Esq., 20th October 1686, in which is noted a list of twenty "Qualities and Operations," which he says characterize "The Herb called Tea or Chee." With the qualities and operations of this "innutritious plant"—as its foe, R. Montgomery Martin, Esq., of Voluminous Colonial Statistical memory was wont to call it—we have nothing to do, not being at present in the tea-trade. At the close of the list, however, the transcriber volunteers the information that "the Chinese believed implicitly in the virtues of the herb as summarized above," of which, he says, "we have evidence in the records of the travels of two Arab merchants, who visited China in the years A. D. 851 and 867. From this we learn that tea, under the name of Tcha, was universally drunk, and was supposed to be a cure for every disease." As the copyist does not mention the name of the Arabs whom he cites, we are left to guess who they may have been. That they make the statement which is credited to them we take the liberty to doubt. We shall see in moment that, when it comes to quotation, the authority of our hebdomadal friend is exactly nil. The Chinese have long been in the habit of using tea. When or how it came into use is probably not known. The conjecture of Baron Richthofen is, perhaps, as good as any other. According to his hypothesis, the water of the swampy and malarious rice-fields of the south was found to be, in its natural state, unhealthful; and it was therefore boiled. To correct the insipidity which resulted, an infusion of the leaves of plants was tried. Of the leaves so experimented with those of one particular kind of plant were found to be much superior to all others. Hence the use of tea. That the Chinese are strongly attached to their tea is unquestionable. So are the population of England, and of the United States. But that the Chinese believe that the tea-leaf is a "cure for every disease" we shall again be obliged to doubt, until it is supported by some stronger evidence than the quotations of our hebdomadal writer. Else what means the common proverb, which has quite a different look: 'Tea does an hundred mischiefs, and only one good—it lightens the eye,' which last statement corresponds to Mr. Povery's virtue No. 9 Excessive tea-drinking is said to interfere with the all-important Ch'i as is seen in the fact that tea-drinkers cannot walk without panting and puffing In short, all the five viscera are injured by tea. This, however, by the way.

We are next informed that "Marco Polo, the famous mediæval traveller, also distinctly mentions tea in his travels in the East." Our hebdomadal friend is good at copying rare manuscript, but, as we have remarked, he does not shine in quotation. He appears indeed to have confined himself to the manuscript department of the British Museum. It is well known, however, that there is an enormous library in that respectable institution, full of books for reference and consultation. If he had taken the trouble to stroll round to the librarian, and ask for "The Book of Ser Marco Polo the Venetian, newly translated and edited with notes by Colonel Henry Yule, C. B." (the

last and incomparably the best edition of Polo that has ever been published) and had turned to P. CXXXX of the compendious introduction, he would have found the following passage :—"In no respect is his book so defective as in regard to the Chinese manners and peculiarities. The use of tea, though he travelled through the tea districts of Fokien, is never mentioned." Three Chapters (LXXX—LXXXII) are devoted to the "Kingdom of Fuju" [Foochow] and its cities ; yet, though we have notices of ginger, sugar, and camphor, of silk, cotton and spices, there is neither here nor elsewhere, anything said, or hinted, about tea. We have not the slightest idea that anything that we can say will discourage this style of quotation. We know London newspaper people too well for that. If we were not opposed, on grounds of political economy, to betting, we should be willing to lay a wager that the very next time one of the English or American newspapers launches into an essay upon the antiquity, virtues, and so forth of this plant, we shall meet again the calm affirmation that "Marco Polo the famous mediæval traveller also distinctly mentions the tea-plant in his travels in the East."

PLANTING EXPERIENCES IN JAVA.

(Extracts from a letter written by an ex-Ceylon planter, who lately proceeded to Java.)

The climate here is fearfully damp, and we have had rain nearly every day for the last three months : in fact, I should say the place was better adapted for tea than for coffee ; no one seems to know when we ought to get the hot weather !

The Javanese lingo is something awful ; the coolies speak high Javanese to you, and you have to talk to them in the low. There are different races of coolies in different parts of the island, who speak Malay, Sundanese, Madurese, &c., &c. So that, if you change to another district, you very probably have to learn another language, although you can generally get on with Malay by working Malay mandors, who take the place of Ceylon kanganies.

Chinese are by far the best workers we have here, but Government will not allow them to work in the interior. The Javanese are the laziest lot of scamps I ever saw, and do only about a third of a good Tamil cooly ; they are very much like the Sinhalese in one respect and fight shy of a shower of rain. If it lasts for about an hour, off they go to their huts. They get 40c per day, and we have to give them curry and rice, and cook and carry it to the gentlemen in the field. Each of these aristocrats has his cigarette case, cigarettes, and box of matches, which he always takes with him to the field and smokes at all hours of the day : *they always buy their cigarettes ready-made.* It 's rather amusing to see them after their lunch at 11-30 a. m., pull out their cigarette cases, and discuss, probably, politics : how I should like to have a hundred Ramaswamies here.

The bungalows are built solely of bamboo, split bamboo for the roof, and plaited bamboo for the walls; so that, when there is a breeze, it blows through all your rooms, which is not particularly pleasant. The bungalows are all on the groundfloor and are always damp. When it rains, your floor is all over small puddles, for the roof is anything but watertight.

Coolies are mustered at daybreak and go on working until dark. The day's routine here is very different from that of Ceylon : we rise at 6 a. m., have coffee and read the papers, have a bath and breakfast about 9-30, go out to work and come in at 12, have rice table and a nap, then coffee and go out again about 2, and work until dark. Dinner at any time up to 9 o'clock. I live chiefly on curry and rice. No meat at all, for it takes two days coming here, and by the time it arrives is always tainted and unfit for food.

The coolies are paid three times a month, 10th, 20th, and last of the month, on which days there is no work, and these three days are the only holidays we have, for we work on Sundays also.

The mosquitoes here are something awful, and the coffee swarms with them, and, unless you keep on smoking like a chimney, you get worried to death. I believe the reason is that the place is one mass of weeds, and only gets hacked over with a mamotie or sickle every two months. So the animals have plenty of time to increase and multiply.

The ordinary coffee borer has been attacking cinchona lately ; I do not think I ever heard of this in Ceylon.

COFFEE LEAF-DISEASE.

Last night Mr. Marshall Ward lectured before the Linnæan Society on coffee leaf-disease. Your agents having been requested by me to send a shorthand reporter to attend the meeting, you may possibly be furnished with his extended report by this mail; but, as the transcript of his notes may not be ready, it will, perhaps, be as well to give you my own recollection of Mr. Ward's address. He did not read the whole of his paper, which is a lengthy one, and will, of course, be eventually published in the *Journal of Transactions*. Mr. Ward contented himself with sketching the life-history of the disease, illustrating his subject by chalk sketches on the black-board. He proceeded to describe how the spore of the fungus adhered to the leaf, and, germinating, threw out its sucker, which, piercing the leaf, formed the *mycelium* within it. Then he showed how from these *mycelia* the red rust was formed on the lower side of the leaf, which in its turn proceeded to produce fresh spores. It was remarkable, he said, how accurately it was possible to determine the time from the settlement of the spore to the development of the rust. He narrated the result of his experiments with coffee plants from Jamaica, and how soon they took and developed the disease ; both when planted out or artificially inoculated. He concluded by saying that, although he could not pronounce the discovery of any cure, he had at least succeeded in establishing the life-history of the disease. Mr. Ward only spoke for about twenty minutes and then sat down. Mr. Thiselton Dyer said that he felt the most entire confidence in Mr. Ward's experiments and the results he had deduced from them. The information obtained was of a most important character, and might do something to stay the great falling-off in coffee exports from Ceylon, as to which he quoted figures. He said Mr. Ward's task had been a most difficult one, for he had to overcome and dispose of all sorts of previously conceived theories, such as that the disease was constitutional and took its rise from the very roots of the tree. He must say, however, that, as regards the approximation to any system of cure, he much feared the question was pretty much where it rested before Mr. Ward went out to Ceylon. From Mr. Ward's investigations it was evident that the development of the disease, from the lodgment of the spore to the completion of the evil, was exceedingly rapid. Too much so, he feared, to enable remedial measures to have any effect, and he could not but dread that a cure would be as undiscoverable as has been one for the potato-disease. It was possible, he thought, that screens of thickly planted trees against the direction of prevailing winds might be serviceable in arresting the carriage of spores by their agency, or at all events might considerably filter them off. He said Dr. Trimen's efficient and cordial aid to Mr. Ward should be acknowledged, Mr. Carruthers, of the British Museum, then rose, and said that he considered Mr. Ward had done much towards filling up the gap in their knowledge of this

disease, but he must agree with Mr. Dyer in his fear that a cure would remain as undiscovered as in the case of the potato disease. There was one point of hope, however, and that was that, although the development of the coffee leaf-disease was rapid, it was as nothing as compared to that of the potato-disease. The development in the latter case took only as many hours as days were occupied in the former. He should like to know if the much-talked of Liberian coffee resisted the disease, as it was evident the Jamaica coffee experimented upon had failed to do so. Mr. Ward, in reply to Mr. Carruthers, said that he could claim no immunity for Liberian coffee, but it seemed to him that, owing to the large amount of leaf carried by this variety, and the great size and thickness of its leaves, it was able to support the attack of the disease, and yet yield heavy crops of berries at the same time. The President, Mr. Thomas Crisp, then thanked Mr. Ward for his paper, and the meeting proceeded to the discussion of other topics. I was glad to welcome Mr. Ward back to England, and to observe that he showed but few signs of having suffered from his temporary expatriation.—*London Cor.*

THE SPICE TRADE IN THE UNITED STATES.

Here, in America, as in other advanced countries, modern habits of living are developing a taste for more highly-flavoured foods, and from this comes an increased use of spices. This is easily shown by the statistics of imports of these pungent products of tropical climes. The result has been that of late years a large trade has been built up in importing, grinding and packing spices for table use. New York city leads in this direction. In addition to numbers of firms located at this port, who bring these products into the country, there are in New York alone twenty spice mills. The important products forming the bulk of the trade are pepper, ginger, nutmeg, cinnamon, allspice, cloves, mustard, mace, cassia buds and curry powder. The first four named constitute the largest quantity sold, and in the order named. London is the spice market of the world, quarterly sales being held there which determine prices for all localities. The bulk of the spices used are raised in English and East Indian colonies deriving their supplies largely from Great Britain. These are paid for by return shipments of pepper, nutmegs, cinnamon, etc. For this reason, London has heretofore monopolized the trade in the best grades. Of late, however, importations to the United States have been made of high-class spices, and the time appears not far distant when this country will do her purchasing of these commodities direct from first hands to a large extent.

The growth of the trade in the United States is said by good authorities to have been at least 10 per cent. during the two years past. Since 1870 it has increased in a marked degree. Some statistics drawn from government reports will illustrate this. During December 1880, the value of the imports of spices amounted to $154,135; in December the following year the total was $196,176. Again in January 1881, the month following the first given above, the value of the spice imports was $87,830, against $154,776 in January 1882. During the seven months ending January 31st, 1881, the value was $1,216,233, and in the corresponding seven months ending January 31st, 1882, the total was $1,937,944. During the calendar year 1880 the value of spice imports into the United States was $2,241,156, and in the twelve months of 1881 it was $2,355,032. The last totals given show the growth of the trade in the last half of 1881 when the total for the fiscal year ending June 30th, 1881, is recalled—$1,700,267.

The intricacies of the spice trade are due to the numerous grades and the methods of packing, which to the uninformed are the cause of doubt whether they represent different qualities of the same product, or like products from different localities simply. Broadly speaking, the latter is true. Thus, the four varieties of cinnamon are known by the country where grown, China, Saigon (French E. I.), Java and Ceylon; cloves, Amboyna, Bencoolen and Penang; ginger, three grades from Jamaica, Cochin, African and Race. Mace is from Penang, where nutmegs are grown, the former surrounding the latter, which grows somewhat similar in appearance to the walnut. Black pepper, which grows in a berry form, upon vines which cling to trees, is procured at Singapore, Sumatra and Batavia. White pepper is prepared from the black, and is obtained in perfection from Tellicherry; while red pepper, which grows in pods upon bushes, is imported from Bombay and Natal, that obtained from the latter place being the finest. Curry powder, from the East Indies, long in use in England, has only recently received extended favor in the United States. The special prominence given to the spice trade of late has been due somewhat to the controversy going on among dealers relative to adulteration. It used to be readily admitted by grocers that ground spices sold by them were adulterated with harmless ingredients. It was claimed that absolutely pure spices would not prove acceptable to consumers owing to their great strength. In this way a popular acceptance of the notion justified or permitted a very large amount of adulteration. Recent efforts toward reformation by grinding and selling absolute pure spices have not only excited, as stated, considerable feeling, but appear to have gone far toward showing that pure spices are as necessary as pure food, and far in advance of the adulterated article in the matter of flavor.—*Bradstreet's.*

THE PIASSAVA: OR ROPE-BEARING PALM.

(From "Notes on New Industries." By ARTHUR ROBOTTOM.)

Although this article has been before the British public for nearly 40 years, very few persons know its origin, where it comes from, or how it grows. Being one of the first to introduce it to the trade throughout Great Britain, Germany, France, Belgium, and Denmark, and having travelled through the forests in Brazil where it is collected, a few remarks from me may be of interest. The word piassava means a rope-bearing palm, and the districts where the trees thrive are Una, Taperoa Cammamu, Ileous, Canaverious Marayu, Morro San Paulo, Boypepa, Porto Seguro, Rio de Contas, Belmonte Santa Cruz, and Cammandatuba, all situated in the Province of Bahia, Brazil. The first-named district is about 80 miles south of the town of Bahia and the forests extend to the Rio Pardo. The fibre grows from the beard of the leaf to the length of 10 to 14 feet. The natives climb the trees, which are from 30 to 40 feet high, and make a nick in the first leaf which bends so that the man can stand on it with safety; the piassava is then cut down, each tree giving from 20 to 30 lb. The natives have a great objection to cutting it during rainy weather, as in the wet season the venomous snakes are known to conceal themselves within the trees for shelter. After being cut down the piassava is taken to the nearest village and cleaned in a rough way by fixing pieces of sticks in the ground with sharp points, and the piassava is drawn through this rude cleansing apparatus, so as to remove the flossy fibre, the bulk of which is sold for consumption in Brazil for making ropes to tie poles together, or for making fences, &c., and in several native villages that I have visited I found the huts were made entirely of poles fastened together by this piassava rope, and covered with leaves from the piassava tree. The fine and flossy part, which is

useless in this country, is much esteemed in some parts of Brazil, for I noticed that many of the mules going up to Farer St. Anna, a district situated a long way from where the piassava is grown, were loaded with this flossy piassava. After being cleaned the piassava is taken to the sheds which are generally erected by the side of the rivers, to be pressed; it is then packed in bales and bundles and put on board the lauches to be taken to Bahia from whence it is shipped to Europe and elsewhere. During my visit I stayed for a short time at a native hut in the district. My food consisted of mandioca, mixed with a few eggs and water, and baked on burnt clay, and sometimes dried fish (young shark) was included in the baked dish. I never saw any bread all the time I was in the district; an old dark woman performed the office of cook, mixing the food with her hands which somewhat resembled the paws of a monkey. At night I slept upon a long board cut from the rosewood tree, and which virtually was my bed. The native hut was completely covered and protected with the leaves of the piassava. The piassava is sent principally to London, Liverpool, Hamburg, Antwerp, Havre, and some small quantity to Portugal, and sold to the bass dressers, who employ men to cut it into lengths from five to fourteen inches; it is then sold in this state to the brush makers who manufacture it into brooms (called "bass" brooms) for sweeping yards, stables, roads, streets, &c. The brooms used by the sweepers of the London streets and of many provincial towns are made of this material, and I notice these brooms already in use in the convenience erected by the Duke of Bedford, for the use of the market people. Such places supplied with such brooms ought to be largely multiplied in London. In some parts of England the brooms are miscalled "whalebone" brooms; on shipboard they are called "coir," while in Yorkshire they are known as "weed" brooms. I was told in Bahia that the name "bass" brooms was given to the piassava owing to the dealers in the early days of the trade having paid for it in "Bass's" pale ale. Piassava was first introduced into this country in the form of long ropes, and the "fenders" now so well known and used for placing down by the side of vessels when passing through the docks, or when coming in contact with other ships. Shortly after its introduction a portion of one of the fenders got into the hands of a working brushmaker, he made a broom which answered well. About this time the bulk of the sugar which was shipped from Bahia was packed in cases of about 16 cwt. each, and small quantities of piassava were used as dunnage, and lots of 2 to 3 tons would come forward principally to Liverpool. At the period of time I speak of I had business relations with Mr. Richard Dean, of Birmingham, a manufacturer of broom stocks. I induced him to begin to keep the piassava and retail it in small quantities to poor Irishmen who work principally in garrets. These men would buy from 14 lb to 1 cwt. on the Monday, and with the stocks and a little pitch make up the brooms and hawk them about at the end of the week, many of the brush-makers refusing in toto to enter into competition with the besom-makers (who were principally gipsies), the Irishmen began to make money by their work, and before long the brush-makers gradually began to get into the trade.

As the business is likely to increase it is necessary that some movement should be made to induce the people in the country where the piassava trees grow, to plant fresh trees and make regular plantations in the same way as already has been done in the cases of coffee, sugar, cotton, and cocoa plantations. It is clearly evident that we cannot depend on the future supply by the present natural, though precarious mode of planting, which is entirely due to small animals and birds carrying the coquilla nuts (the fruit of the tree) from one part of the forest to another, leaving the nut on the ground, which, in the course of a little time, springs up into a piassava tree. On the top of the piassava tree a large bunch of these coquilla nuts grow, they are used in some parts of Germany for making the bowls of tobacco pipes, small tops, and other fancy articles. While I was in the forests I had one of the piassava trees cut down, with the piassava and coquilla nuts in full growth, and when the tree was in its full beauty. I had it sent up to Bahia as a specimen, for although the district where the trees grow is so near to this large city, many of those who deal in this product have never seen it grow in the forest. Although I have travelled over a considerable part of North, South, and Central America and other parts of the world, there is no sight more beautiful to my fancy than a forest of piassava trees. My only drawback in travelling in this part of Brazil was the want of a proper lodging-house, or place to sleep in. If I could only have been sure of getting a bed or accommodation equal to what our casuals get in our workhouses in England, and free from lizards, centipedes, snakes, musquitoes, and a hundred other lively companions, my happiness would have been complete.

I have tried to introduce the trade of making bass brooms into Naples, Rome, Genoa, and other parts of Italy. In Naples the streets are swept with small boughs of trees tied together, and few sticks made into a bundle. Although I have completely failed to get small manufacturers to start the business in Italy, I am quite convinced in my own mind that, if any one started the bass room making, they would soon find a ready sale in every city in that improving country. The export of piassava from Bahia to Europe in 1881 has been 336,288 packages, 507,157 arrobas, equal to 7,245 tons English; of this quantity nearly 6,000 tons was imported into England.

Para piassava or monkey bass is obtained from trees of the same family of palms as the Bahia piassava. The trees grow by the side of the White River and other streams that flow into the Oronoco and the Barra de Rio Negro, and are sent down to Para for shipment to England. This kind of piassava, which is of a finer quality than the Bahia piassava, realizes considerably more, and is used in making small brushes for cleaning cloth, &c.

Bass brooms were introduced into Dublin by Mrs. E. Wilson, the owner of the "Favourite" omnibuses in London, that lady going over herself to Ireland and finding out the necessity for such reform as can be brought about by the free use of these brooms. She accordingly sent over a new omnibus full of the new brooms to Dublin, starting the trade in Ireland in this way.

Before piassava became such an important item of commerce from Brazil, the natives in the districts where it is collected lived a very indolent, useless existence; they employed their time to a limited extent in hunting, and their food consisted mainly of the mandaoca mentioned above. Very different, however, is the state of things today. The collecting of the piassava from the trees now finds work for hundreds of men, while as many are required to clean and press it. Labour is also in great demand for transporting, it and placing it in the Trepech or warehouse in Bahia, and from the Trepeche to the vessels for shipment to England. From this point the English labour commences: sailors to bring it to England, dock labourers to discharge the cargo and warehouse it in our docks, subsequently carters and lightermen to remove the piassava from the docks to the works, porters and railwaymen to carry it to the works and place it inside, men to steam it, men to cut it, men and boys to comb it, packers to pack it for home and

foreign consumption, men and boys to bore the holes in the stocks to receive the piassava, and men, boys and women to make up and turn out the finished article. Nor should we forget, in conclusion, the large number of men employed in the metropolis, and elsewhere, in sweeping the streets with these very piassava brooms. The traders in piassava may be classed as agents, merchants, brokers, and dealers. The dealer buys it from the presser and consigns or carries it to Bahia to the agents. Merchants buy it and ship it to the merchant sin England. The English merchants employ brokers to sell it. The dealers in this country buy and sell it to "bass" dressers who manufacture it and sell it to the brushmakers. It should here be remarked that the labour performed in the cutting and bailing of the material must necessarily be executed by natives owing to the conditions of climate and habits of life. The improvement in the condition of the natives, and the general progress of civilization since the opening up of the piassava trade is very marked.—*Labour News.*

HEMP CULTIVATION IN MEXICO.

The hemp industry in Mexico has, within the lats ten or twelve years, attained considerable proportions, and one of the chief articles of trade in Yucatan is the fibre extracted from the hemp plant, or American aloe, commonly called by the Indian name of "henequen." Consul Lespinasse states that the plant is found in profusion throughout Yucatan, and forms the nucleus whence all the present hemp plantations have been formed. The hemp tracks are divided into "mecates," which is a Mexican measnre of twenty-four yards square. After all the shrubs and weeds have been burned during the previous dry season, the Indian laborers proceed to dig small pits, in a straight line, from six to eight feet apart, and between each line of pits, a path about nine feet wide is left clear, in order to give the laborers sufficient room to cut the leaves when they have attained their full growth. As soon as the required quantity of land is thus laid out, the young plants are cut close to the grennd, and, without any process, are simply placed in the pits prepared for them, with a little loose earth, and are left to take care of themselves. Each "meccate" contains about 96 plants. Twice a year the ground is cleared of the underwood. As the plant grows, a stem shoots out from the centre, and the leaves gradually detach themselves from it in a spear-like form with sharp prickles along the edges, and a strong, black, sharp needle-like thorn at the point. The plant requires from five to seven years to attain its full growth. At the end of this period, the leaves have an average length of four feet. A hemp plant will flour sh from ten to fifteen yeares. Each plant has about twenty-six leaves during the year, sixteen in the rainy season, and ten in the dry; each leaf, four feet long, produces about three-quarters of an ounce of fibre; it requires, therefore, from seven to eight thousand leaves to make a bale, weighing four hundred pounds. As soon as the plant has attained its full growth, the leaves are cut from the trunk commencing from the bottom upwards, only those being cut which are well developed. From the hemp beds they are carried to the scraping machine, which consists of a strong fly-wheel, on which six or eight blunt brass knives are placed transversely. The leaves are placed one by one on a curred lever, which is raised or or lowered in such a manuer that the knives on the wheel only strike the pulp and lay bare the fibre. First, one end of the leaf is presented to the wheel, and, as soon as it is scraped, the other end is presented. Each time one end is introduced, the other is secured by a strong pair of iron pliers, which are attached to the machine. Each machine employs four men, one to place the leaves near the machine, one to attend the lever, one to introduce the leaves into the machine, and the fourth to carry away the pulp and refuse matter. As a rule, the machines are worked by steam-power, and can clean about four hundred pounds of fibre in one day. When the fibre is extracted from the leaf, it is taken to the drying yard and hung on slender poles, which are stretched on wooden frames about three feet from the ground, and left to dry and bleach in the sun. If the weather is fine, it will become dry in four or five hours. While drying, the fibre loses its natural greenish hue, and assumes a white, glosey appearance. It is then placed in hydraulic presses, and compressed into bales of the required size, which generally weigh three hundred and fifty, four hundred, and five hundred pounds. The fibre is then ready for shipment.—*Fiji Times.*

EXHIBITION OF BRAZILIAN COFFEE:—INAUGURAL DINNER AT THE CRYSTAL PALACE.

An incidental reference to coffee as a public beverage, made by the Prime Minister in his last Budget speech, has naturally attracted more than usual attention to this subject, it is therefore at a moment especially auspicious that the first exhibition of Brazilian coffee in this country is now open to view at the Crystal Palace, and practical means adopted to supply the English public with reliable information as to the quality and other merits of this important product of the great South American Empire. It will doubtless be a surprize to many to learn that the total amount of coffee grown in Brazil during the year 1881 amounted to about 5,000,000 bags of 120 lb each, being equivalent to one-half the whole estimated consumption of the world. Of this prodigious quantity, in the same period, 2,241,976 bags were exported to America and 2,135,442 bags to Europe, England receiving 266,756 cwt. of the latter, and yet to the vast majority of people Brazilian coffee is quite unknown. From its superior and delicious flavour, it, indeed, enters into consumption as a component part of many of those execrable mixtures which have done so much to discredit and limit amongst us the use of the aromatic berry, but is seldom if ever sold in our grocers' shops in its own name and in its native purity. The "Central Association of Agriculture and Commerce of Rio de Janeiro," under the auspices of the Imperial Brazilian Government, have—and not too soon—resolved to put an end to this unsatisfactory and anomalous state of things by opening exhibitions in the principal cities of Europe and by otherwise popularizing the Brazilian product by the diffusion of statistical and authoritative data with respect thereto.

It would be difficult to exaggerate the valne to Brazil of this new departure, and the friends of the Empire are to be sincerely congratulated on the very effective display of its coffee submitted to public inspection at the Crystal Palace. To Commendador J. L. C. de Salles, the Consul-General for Brazil, upon whom has devolved the arduous task of making all the preparations for this interesting exhibition, and and who has evidently spared neither labour, thought, nor money to render it complete, the merit of achieved success must be frankly awarded, and it cannot be disputed that the position selected for this unique display in the Crystal Palace has been well and judiciously determined.

While all the arrangements manifest a careful regard to the practical objects in immediate contemplation, artistic effects have not been neglected, and the scene which strikes the eye of the spectator on entering the central avenue of the Palace, where the exhibition is located, is calculated to at once arrest attention. Than this central avenue no more

advantageous position could have been secured, the aspect of the building at that point being most impressive, while in no part is it more frequented or more accessible to the crowds of visitors who constantly throng its galleries and corridors, at present illuminated with all the splendours of the electric light. There, neatly assorted, are a large number of small sacks lined with blue cloth, containing different samples of Brazilian coffee, from the principal "fazendas" of the provinces of Minas, Rio de Janeiro, San Paulo, and Espirito Santo, and the necessary explanatory particulars are conspicuously provided in documents prepared and printed for the purpose by the Consul-General. We also noticed a map of the world, on which the various coffee producing regions are marked, and which, more eloquently than words could do, must impress every beholder with the great fact that, in comparison with the coffee-growing surface of Brazil, all other countries shrink into palpable insignificance. The *tout ensemble* is also much improved by a number of fine views of the most picturesque and attractive points of Brazilian scenery, the whole display being loyally surmounted by the Imperial arms of Brazil.

It was only fitting that this useful Exhibition should have been inaugurated with some degree of observance, and we are pleased to record that, on Saturday, the 13th inst., with this object, Commendador J. L. C. de Salles, to whom we have already alluded, entertained at dinner, in the Crystal Palace, a distinguished and brilliant company of ladies and gentlemen connected with and otherwise interested in Brazil. * * *

The Chairman, in responding to the toast, which was drunk with enthusiasm, expressed his high sense of the honour the company had done him in drinking his health with so much cordiality, and this token of the approbation of so many influential friends of his country encouraged him to persevere in the grand work which they had that day assembled to inaugurate. (Hear.) His Excellency the Baron de Penedo could testify that he had many difficulties to overcome, but these he had surmounted, he trusted, in a manner not altogether discreditable to himself nor unworthy of Brazil. (Applause.) He had endeavoured to obtain the use of the Kensington Museum for the purposes of their exhibition, being anxious to secure a place in the centre of London capable of accommodating a large gathering of people, to taste of the produce of Brazil in its pure and unadulterated state, but the authorities, though agreeable to assist, could not see their way clear, as their doing so would establish a precedent which might be of much inconvenience to that great national establishment; and he could not find fault with them, when he considered that England, possessing her own coffee-producing colonies, might not be over-anxious to promote the objects of a Brazilian Coffee Exhibition. (Laughter.)* He had finally determined upon engaging accommodation for six months or a year for their exhibition in the splendid building within whose walls they were now assembled, and with the result they had, he confessed, many reasons for congratulation. (Hear.) Of one thing he felt confident: that when the people had an opportunity of drinking Brazilian coffee in its purity they would learn to prefer it to the produce of any other country, as no better coffee grew in any part of the world, and of late years, he was glad to say, the attention of the growers had been very successfully directed towards a more careful preparation of the coffee produce of their great plantations, to meet and to merit an increased demand. (Applause.) He was also glad to know that this had been corroborated by a considerable number of persons who were excellent judges. The importance of the objects of the exhibition to Brazil would be evident from the fact that its Exchequer derived a large portion of its revenue from this source, while a considerable part of the native capital was employed in the cultivation of coffee, and he hoped that the influential committee of gentlemen at Rio de Janeiro, who had so ably and patriotically originated and conducted this great movement, would soon reap for their country the expected results of their arduous and beneficent labours. (Hear, hear.) In common with every friend of Brazil, he was much pleased to note the reference made to coffee in the last Budget speech of Mr. Gladstone, in which he announced the future intention of the Government to allow of the admixture of no other substance with coffee save chicory, so that the public might be protected against the vile compounds at present sold to them as coffee. This was a step in the right direction, and would materially promote the honest objects of their exhibition. (Applause) All that they wanted for Brazilian coffees was fair play, and no favour. In conclusion, he had no doubt that the efforts they were now making would tend to greatly increase the consumption of Brazilian coffee, which had only to be known for what it really was to be universally appreciated, bestowing not only a benefit upon the producing country, but also upon the consumers. (Applause.)

Before their departure, the guests adjourned to the adjoining reception room, where they partook of Brazilian coffee, prepared in such a manner as preserved in perfection all its aromatic fragrance. Served in cups of superb Sevres porcelain, specially made to grace this inaugural ceremony, with little golden spoons very artistically and elegantly chased, this delicious beverage elicited the unanimous award that Brazil was not only first in point of production, but also as to quality deserved to be called the King of Coffee.—*South American Journal.*

* A piece of silly impertinence. The refusal was given on good grounds of inconvenient precedent. If this request were granted how could the request of the American Government to exhibit wheat, the Buenos Ayres Government to exhibit dried beef, and so on, be refused?—ED.

PLANTING PROSPECTS IN CEYLON.

Special attention has been called to the case of hard working proprietor-superintendents of estates, of proved probity and steady industry, on whom mortgagees may be inclined to press hardly during this year of scarce and dear money and financial distrust generally. The hope is expressed that foreclosures in such a season, may be few and far between—an abatement of interest being a wise concession in such a year of difficulty with planters who have good prospects in the new products which are fast coming to their aid.

The utmost activity prevails throughout our planting districts, notwithstanding the woefully short coffee crop on the trees. The planting season is now fully on, and advantage is being taken of it to add to the area under cinchona, tea and other products. Cinchona plants are being put out among the coffee, along paths and drains and in separate clearings with much more care than was the case, as a rule, in past years. The fact is now generally recognized that to too hasty planting, or rather to the throwing-in of plants, is due a large proportion of the failures since 1878. Immature seed will account for a large share of the balance. Henceforward, however, plants from selfsown seedlings will be making a show in many districts, and alto-

gether there can be no doubt that a year hence the wealth of the colony in cinchona will be much increased. This result will be greatly helped by the attention paid to the selection of the more valuable kinds —whether in Ledgeriana or the less-approved species. Some trees of the "hybrid" (*C. robusta*, which is so vigorous in growth) have already produced a bark giving nearly 10 per cent of sulphate of quinine. It

At the same time, it is evident that our planters have been remiss in not experimenting for themselves as to the requirements of their soils and so supporting the trees against the attacks of the fungus. There are individual plantations in the country, in this year of pre-eminently short crops, which are doing exceedingly well, but which ought to be no better than their neighbours, if the ordinary view of leaf disease was the correct one. How, for instance, is the case of Yoxford estate, Dimbula, to be explained? In most other instances where a good crop is spoken of, the answer is:—"Oh, what did that place do last year or the year before? Nothing at all. It is now getting a fillip as it was bound to do after successive bad crops." But Yoxford, we are glad to say, gave a good crop last year, a satisfactory one the year before, and now we have what is, for these times, a big crop upon a big crop. A great deal of the area planted is fourteen years old: the elevation, soil and lay of land are no doubt well suited for coffee; but there are probably many hundreds, if not thousands, of acres which show similar natural advantages, and yet do not bear crop in the same way. The reason for the difference here and in one or two other instances which have come under our notice, is well worthy of enquiry. The proprietor of Yoxford is surely justified in attributing his success to the careful experiments he has carried out to discover the fertilizing substances best suited to his plantation. Mr. Bosanquet was, in England, a pupil of Mr. Lawes, and his action has been often the well-known example of Messrs. Lawes and Gilbert and also of M. Ville. He has, for instance, experimentally proved beyond all dispute, as we consider, that nitrogenous manure (and since this characterizes three-fourths of the manures applied to plantations hitherto, must cease) is worse than thrown away on the higher portion of Yoxford. Instead of blossoms and berries, an excess of wood is the result, and Mr. Bosanquet has quite settled that castor cake or other nitrogenous manure is not required, at least for the upper portion of his property. A few experiments probably not costing more than £50 ought to determine after a more satisfactory manner than the best analysis of soil, what the planter should apply to his different fields. But so far, systematic attempts, after the fashion adopted on Yoxford, have been few and far between. To this complexion howeverit must come, and the sooner systematic scientific cultivation is carried out on all plantations fairly suitable for coffee, the better. Meantime, in this year of doubt and depression—when coffee is spoken of by one and another as doomed—we are justified in asking how the good crop on Yoxford or on Balmoral is to be accounted for. The latter is usually referred to as an exceptionally fine piece of land; but it cannot be said that Yoxford is specially favoured beyond other places along the side of Great Western, from Medacumbra up to Galkandewattie. Let critical Visiting Agents explain the difference before they begin to cry down the coffee enterprize.

In Liberian coffee, cocoa, cardamoms and India-rubber, the prospects are good and the extension of cultivation is steadily going on. In connection with the last-named we have just published a manual (on 'India-rubber and Gutta Percha") after the pattern of those issued from our office on cardamoms, cinchona, Liberian coffee, &c., from which we trust intending planters will derive much useful information.

NEW INDUSTRIES: DYES.

We take the following extract from Mr. O'Conor's very interesting report on the foreign trade of India for 1880-81:—

"Aniline dyes, cochineal, and saffron are the three principal items under this head *(Dyeing and Colouring Materials)*, the importation of aniline dyes increasing from year to year in a way which causes apprehension to those who are interested in the continued use of the Indian vegetable dyes, superior as these are to the aniline colours, both in richness and variety of tint and permanence. Aniline dyes are cheap and easily worked, and it seems likely that their use will extend to the detriment of Indian dyes. The imports in 1878-79 amounted to 1,145,208 ounces, in 1879-80 to 2,507,794 ounces and last year to 3,555,310 ounces. They are apparently not only affecting the foreign markets for Indian dyes, but threatening to supersede the latter in India itself. The art of dyeing in India, though probably the oldest industry in the country, may be said to be in its infancy as regards the process employed. It is carried on by the people in the smallest way with the roughest apparatus, and by the most tedious processes, without the aid either of capital or machinery, and unless the business is taken up by European or native capitalists, and conducted on a large scale, with the aid of the latest developments known to European skill, it is quite probable that it will not long compete with the cheaper, quicker, and easier processes used for dyeing with aniline colours. Both in an artistic and in a commercial point of view this result will be very regretable, and it is to be hoped that the prospect of gain may induce capital to take the business up. It is one in which handsome profits may be certainly looked for."

We have quoted this passage, in the first place, in order to bring a very important matter to the notice of enterprizing capitalists; and, in the next place, for the information of those who, with the *Hindoo Patriot*, contend that the import duties had no protective tendency. The foreign aniline dyes used to pay an import duty of 5 per cent, and, though it was not sufficiently protective to enable the native dyes to hold their own, still it is evident that it must have been protective in a degree, and it is probable that its removal will very considerably hasten the consummation predicted by Mr. O'Conor, if capital continue to neglect this decaying industry —*Friend of India.*

HILL GARDENING AND CINCHONA IN WESTERN INDIA.

MAHABLESHWUR, May 5th.—There are at present three or four Chinese living at the station, one of whom owns a large garden near the lake. The English gentlemen, who founded this sanitarium, took a great

deal of interest in the gardens; their ladies especially took pains in teaching the gardeners the best mode of raising various crops of vegetables, often supplying them with seeds brought from Europe and from other parts. If the ladies of the present generation would only show equal interest, I am sure they would contribute much to improve the products of the gardens, which certainly need improvement. The natives do not read, and are therefore ignorant of the new methods of raising better crops of vegetables and fruits. They invariably, from year to year, follow the same method once taught them, never taking the trouble of selecting good seeds or stock. The potato of Mahableshwur was at one time highly esteemed and reckoned the best in the Presidency; but the old stock has degenerated. What the cause of this degeneration is it is not easy to ascertain. *Varii varia dicunt.* Some say the degeneration is due to the owners having taken up the tubers too early; others attribute it to the crop being grown in successive seasons on the same spot. The latter is, I believe, the true cause of the degeneration; experience has proved that the potato plant does not thrive well when raised in successive years in the same place. Although an intelligent gentleman informed me that he had heard that the potato tubers became black some time after being dug up, I am led to believe from inquiries made that the fungus *Peronospora infestans*, which frequently appears in Europe in an epidemic form, has not as yet shown itself on this hill, sacred to Shiv and Krishnabai.

Last year Dr. McConaghy, the energetic Superintendent, brought tubers from Mussoorie and other parts of India and distributed them among the gardeners here. The crop raised is said to have been good. Major Affleck also brought some stock from England, but failed to raise a good crop.

Raspberries and strawberries are cultivated here. These fruits, with which Europeans are familiar, are susceptible of improvement both in size and flavour. *Rubus lasiocarpus* is the species of raspberry grown on this hill. It is a large, very variable, straggling kind of bramble with compressed prickles: indigenous to Neilgherry, Himalaya, Murree, Cashmere, and other higher ghauts of India and Ceylon. It thrives well here, flowers in February, and fruits in March and April. It delights in rich soil, which is better renewed every year. We read in the Bombay Flora that *Rubus idocus* (the common raspberry of Europe) is successfully cultivated at Phunda Ghaut, south of Kolhapur.

The kind of strawberry cultivated here is *Fragaria Nilgerensis; F. elatior* of the Bombay Flora. It is indigenous to the Neilgherries and Kassia. The Bombay Flora says:—"It is successfully cultivated above ghauts and extensively near Poona for sale in camp. The strawberries of Kolhapur and its vicinity appear to be the best in the Deccan." It is now in fruit here. Abundant water is necessary for raising a good crop of it. *Fragaria vesca*, which is, perhaps, a form of the Neilgherry strawberry, is said to be raised at Saharanpore and Meerut. Supplies of other fruits, such as figs, grapes, plantains, mangoes, &c, are drawn from Poona, Dapoli, Wai and Satara. It appears to me that cardamom *(Elatteria Cardamomum)* could be introduced on the shady places of this hill. Whether an attempt has ever been made, I have not been able to ascertain. The elevation of the Travancore forest, where cardamom is indigenous and cultivated, is from 3,000 to 5,000 feet; the mean rainfall, 121 inches, and the mean temperature 72° F.

Lingmala is a place worth seeing; the distance from the garden is about two miles, and the road leading to it from the latter place is very good; the one ramifying from the Satara road not being in good order. Lingmala is situated on the right bank of the Yenna river, and was the site selected for the cinchona plantations. It appears that about 20,000 young plants, brought from the Neilgherries, were planted here, but four years afterwards, being attacked with *canker*, almost all of them died, and there are at present only a few plants of stunted growth from about three to five feet high, to bear witness to the experiment. There are also here some pear and guava trees, which were, I believe, planted at the same time. They flower and yield fruit, which is small, and I am told not of good flavour. Government abandoned the cinchona plantations in 1875, after spending about R60,000 in the attempt to introduce in this Presidency these useful American plants. The spot selected was not appropriate, being exposed during the greater part of the year to the dry hot winds of the Deccan.* The jambul, hirda and other plants, which become large trees elsewhere on the hill, are at Lingmala bushy. Should Government ever again attempt the experiment, they would do well to select some other spot: perhaps the valley, known to bazaar people as *Concubag*, where formerly a Chinaman tried to raise tea-plants, would be appropriate. *Cinchona succirubra* and *C. Cordifolia* ought not to be thought of again; instead *Ledgeriana* should have a trial.

About a quarter of a mile below the cinchona plantation is the romantic valley to which many people go to see the Yenna waterfall. This is enjoyed best at the end of the rains and during the cold season, when the volume of water is said to be large and the sight magnificent. Here in this valley on the left bank of Yenna, as well as in Wai, there are very handsome trees of *Elococarpus Oblongus*, known here as *Kassou*, which, when in full bloom are very beautiful. They are now beginning to flower; the flowers being arranged in simple drooping racemes; calyx reddish brown and petals white, beautifully fringed. This tree is closely allied to *rudrach* (*Rudrach ganitrus*) also found here, the nuts of which are elegantly tubercled and used as necklaces by Brahmins and fakeers. The nuts of a euphorbiaceous plant, *Putrangiva Roxburghii* are used in the same manner; being strung up into rosaries and put by fond mothers round the necks of their children, on the supposition that they have the virtue of warding off evil spirits and keeping the little ones in health, whence the name, *putra jiva*, "life of the child."—*Times of India.*

APPROCHING VISIT OF MR. STORCK TO CEYLON.

We are glad to learn through the letters in another place that the discoverer of the carbolic acid vapour treatment of the coffee leaf fungus is about to visit Ceylon, and we think the thanks of our planting community are due to Mr. Dobree for acting with so much promptitude and public spirit as he has done in this matter. We have always endeavoured to place the "Coffee Leaf Disease" literature of Ceylon within the reach of every savant or experimentalist interested in the question, and however great may be the doubt entertained of the success of a further set of experiments—after our prolonged disappointing experience—every one must be pleased to see Mr. Storck himself on the spot to watch the effect of his treatment. Should Mr. Storck be instrumental to any extent, in dissipating the present dark clouds which surround our coffee enterprize, he will indeed deserve well of the planters of Ceylon; but at first he must expect uphill work, for so much

* We should have thought that they rather suffered, canker being specified as the cause of failure, from the excessive rainfall of the Bombay sanatarium.—ED.

labour and money have been expended to little purpose in sulphur and lime, carbolate of lime and other mixtures, and experiments, and so little money is now available, that at first he must be contented to prove a success on a limited area to inspire due faith in the utility of more general treatment. One old Ceylon planter writing to us by last mail says :—"Be prepared for Ceylon coffee in February next blossoming out at a rate not seen for a good many years; it wanted rest and it has got it!" Now it is possible that some may be inclined to say coffee is bound to do well next year, whether treated for leaf-disease or not; but this argument will not do for the majority who hold out no such prospect. Besides, Mr. Storck should arrive here in the midst of the usual July-August attack of leaf fungus, and, unlike Mr. Schrottky, as we understand the matter, Mr. Storck can go to work with his cure and shew its effect on the pest at once, without waiting for a particular season.

COFFEE LEAF FUNGUS:—MR. STORCK ABOUT TO VISIT CEYLON.

Udugama, June 23rd.

DEAR SIR,—I send you enclosed a letter I received from Mr. Storck. This was in reply to a letter from me, in which I offered to give Mr. Storck R2,000 on the condition that he did, by his treatment, and at the cost he stated, viz. £2-10s. an acre, keep both a Liberian and an Arabian coffee estate free from leaf-disease for a year. If the experiment succeeded, the expenses of treatment were to be borne by me; if it failed, by Mr. Storck. There can be no doubt that Mr. Storck himself has every confidence in his cure, or he would not come all the way from Fiji to experiment. As I believe his system is being carried out on several estates in the island, we ought soon to know if it is doing any good.—I remain, yours faithfully, T. S. DOBREE.

Belmont, Upper Rewa, Fiji, April 3rd, 1882.

T. S. Dobree, Esq.

Dear Sir,—Yours of Jan. 28th is just to hand, and I am glad to notice some degree of confidence in my treatment expressed therein. It is just possible that, by the time this reaches you, a publication in the *Gardeners' Chronicle* may have appeared in Ceylon, giving an account of the manipulation, etc., of the system; but since writing it I have somewhat changed my tactics, and the thing had better be left untried, until I come myself.

I shall try and get away from here in about two months, so as to be in good time for a campaign in the N. E. monsoon, and we may then arrange about the experiments you speak of.

Should you give publicity to this note, I would be glad of the opportunity of conveying any thanks to the Editor of the *Observer* for his graceful act of attention in sending me Mr. M. Ward's third paper on *H. V.* which reached me since writing to him last.—I remain, dear sir, yours faithfully, JACOB P. STORCK.

THE CEYLON AGRICULTURAL ASSOCIATION.

A public meeting was held at Mr. C. H. de Soy-a's spacious office today (June 24th) in order to establish the Association mentioned above. As will be seen by a reference to the names of some of those present, the Sinhalese, Tamil, and Burgher communities were fairly well represented, the wealthiest of the Sinhalese being specially well represented.

Mr. C. BRITO had much pleasure in proposing that Mr. C. H. de Soyza take the chair. No one had a larger interest in the agricultural enterprize of this island, he felt sure, than Mr. de Soyza.

Mr. BARTON GRINDROD (of the firm of Grindrod, Jenkins & Co.) seconded the motion.

Mr. C. H. DE SOYZA thereupon took the chair. He said :—Gentlemen, before proceeding to the business of the day, I would like to express to you my gratitude for so readily attending here, to make a beginning of such a useful work. The necessity for an institution of this kind has long been felt here, and, seeing the depression in prices at the present time, I thought it my duty to lose no time to call such a meeting, and I would ask your kind help and encouragement. However anxious I might be, I need not say that I would be helpless without your united and individual support. I am extremely thankful for your readiness in agreeing to work, together and this augors well for the success of the proposed Association, which, if properly carried out, will, without doubt, be a boon to our country. Now, gentlemen, I will not take up your time any further but proceed to the business of the day.

The HON. P. RAMA NATHAN then rose and said the chief object of that meeting was embodied in the resolution which had been put into his hands by the Chairman. That object was to promote the interest of those engaged in the cultivation and sale of Ceylon products. He considered that the time chosen by the Chairman for calling that meeting to be very opportune. Any common misfortune would weld together opposing forces, and at the present time of depression he had no doubt that men of varied opinions would unite in the formation of this Association, and contribute heartily to the success and prosperity of that institution. (Hear, hear). There could be no doubt that the institution proposed would be of great use to this colony and to the natives especially. If the Europeans who were so well able to look after their own affairs—who had their newspaper presses, their influential friends in England and their wealth to back up their opinions, think it, or thought it, necessary some 30 years ago to establish an Association to support their agricultural industries he had no doubt they could agree with him that arguments still greater would be found for establishing an Association amongst themselves similar to the Planters' Association. They did not intend to be in opposition to the Planters' Association, but rather to work conjointly with them in so good a cause as the agricultural interest of this country—working unitedly, so as to serve one and the same interest. He asked them to consider with him for a time the interests at stake, so far as the natives were considered, in the agricultural enterprise of the colony. If they turned to "Ferguson's Directory" (a book replete with information upon agricultural questions) they would find that there are about 30,000 acres of land under coconut cultivation and about the same number of acres of land in coffee plantations. Now they would agree with him in his statement that most of the coconut plantations were in the hands of natives, and, as regards coffee the export returns shewed that as much as one-fifth or one-sixth of the produce was native coffee; besides this there was a great deal of plantation coffee raised by the energy of the natives. As regarded cinnamon, 30,000 acres were under cultivation, and almost the whole of it was in the hands of the natives. If interests of such value, amounting to severals million of pounds, were in their hands, he did not see why an Association such as the Planters' Association should not be initiated and worked by them. They had wealth in their midst; they had intelligence and energy in their midst. What then was wanting on their part to do that which Europeans had

succeeded so eminently in doing? He sincerely hoped that all natives, of all classes, would unite in making that institution a success. (Hear, hear.) The cultivation and sale of those products, viz., of coconut, coffee, cinnamon and the new products which had come into existence were—it passed without saying—of vital importance to the people of this island. The natives had now to complete with the trained intelligence and ability of Europeans. Every year which passed made the competition more keen, and unless they moved and asserted themselves they would go more and more to the wall. An Association of the kind now proposed would be very useful in many respects. He would like to point out to them the various benefits which it would confer. In the first place, by means of such an Association useful knowledge might be diffused regarding the nature of soils, the influence of climate upon the produce raised on them, the easiest and most paying and practical methods of cultivation, the implements, machinery and manures to be used, &c. When once a common ground had been established for the purpose of meeting and discussing questions connected with these operations, it was easy to get and disseminate information. Then there were other objects with which that Association might be able to deal. When once produce has been raised it must be sold. As regards sales, it might consider the best methods of selling the produce in the best markets. It might also communicate with the Government on matters of transport, taxation, &c. Undoubtedly their united representation would carry far more weight with the Government than the representation of any one man. There was another object which was of equal importance with the other objects already mentioned. The establishment of that Association would lead the Government to confer with the natives as a body on agricultural and other questions. They knew the importance of the Planters' Association now in existence; its privileges and powers were so thoroughly appreciated by the Government that the Governor willingly asks the Planters' Association to nominate one of its members to represent their interest in the Legislative Council. For a number of years it had been the custom for Governors to appoint the gentleman nominated by the Planters' Association. They would thus see how gradually an institution might be worked into power so as to make itself felt by even Government. He therefore thought that an institution of a similar kind would prove of the utmost benefit to the agricultural enterprize of this colony. All that, as he had already said, was achieved only by union. They must have the force of example and the sympathy of numbers: without it nothing could be done; and he would appeal to all classes of gentlemen of whatever class or creed to lay aside their prejudices and unite together and make that institution a success. He had therefore much pleasure in moving:—

That this meeting considers it desirable that an Association should be established to promote the interests of those engaged in the cultivation and sale of Ceylon produce.

Mr. D. M. Aresecullerathe (Proctor), seconded. The resolution was put and carried unanimously.

Mr. Advocate Dharmaratne, in a rather long speech, considered the idea of a native Association, such as that proposed, an excellent idea. He was very glad such a movement had been started, as it had been his misfortune both here and in Europe to hear so much about native apathy that it was indeed a source of grief to him. But here he saw the twilight that would dispel the obloquy which had been thrown upon natives. The idea should have originated 25 years ago. He then referred to the blessings of English rule, and said the natives had bee slow to take advantage of the opportunities offered b close contact with educated Europeans. They had been content with their jak and coconut and never thought of moving out of the island. Among the Sinhalese and Tamils the idea of leaving the island was dreaded. Such being the case, the obloquy was deserved. He was especially gratified to hear that the natives were to take fresh steps with regard to the *sale* of their produce. He then gave some hints as to a scheme for establishing branches of their new Association in London, Paris and Berlin, which would dispose of produce forwarded by the Association. "What an amount of profit the Association would derive from the sale of coffee, cinnamon, and other products in London, Berlin and Paris." Those branches, in the hands of natives, could undertake to supply all that the natives required to be sent from Europe. Wines for instance. What a boon it would be to get their port wine, for instance, at half price; wine was bought at Paris now and shipped to London and then sent here. Why not buy it at Paris themselves, and ship it here direct from Marseilles? The natives were indebted to the European planter for much of their knowledge. But the European planter had fallen, or partly so. That being the case, it was commonsense that the natives should do their best to find other sources of income. For instances there was ebony. Why should not they make a lot of furniture and sell it in America, London and Paris? He urged then to lose no time in organizing the Association. He moved:—

That the following rules be adopted by this meeting as the rules of this Association, viz:—

Rules and Constitution of the Ceylon Agricultural Association.

I. That this Association be called "the Ceylon Agricultural Association."

II. That a suitable office be secured in the Fort of Colombo where the meetings of this Association shall be held.

III. That a Chairman for each year be elected.

IV. That a Secretary be appointed annually whose salary may be hereafter determined by the Committee.

V. That every person who is the owner of, either in his own right or as lessee, agent, superintendent or tenant, property in cultivation of the extent of 20 acres and upwards, shall be entitled to be elected a member.

VI. That each member do pay an annual subscription of ten rupees in advance.

VII. That a Committee be appointed (of whom *five* shall form a quorum) such Committee to be appointed yearly.

VIII. That the meetings of the Committee shall be convened by the Secretary with the Chairman's sanction or that of three members of the Committee.

IX. That a general meeting may be convened by the Committee or five of its members, or ten members of the Association, on ten days' notice being given, and the business to be brought forward shall be stated in such notice.

X. That the annual general meeting of this Association be held on the 1st of July of each year, on which day the Chairman, Secretary and Committee shall be appointed.

XI. That any member wishing to bring forward a motion or subject for discussion at any general meeting shall give ten days' notice of his intention to the Secretary.

XII. That every member possessed of more than 20 acres is entitled to give more than one vote, and the votes are to be regulated according to the cultivated acreage belonging to each member.

Mr. Jacob de Mel seconded, and the resolution was carried unanimously.

Mr. John de Silva Mudaliyar proposed, and Mr. C. W. Ferdinands Proctor seconded:—

That those present at this meeting and qualified in terms of the fifth rule be considered as original members of the Association on their signing their names to the list now lying on the table.

This was adopted *nem. con.*

Mr. Brito briefly proposed:—

That C. H. de Soyza, Esq., be appointed the Chairman

and Treasurer of this Association for the ensuing year, dating from 1st proximo.

It was admitted that there is a general depression in the country both as to the value of articles produced here and also as to the stability of mercantile interests especially as connected with native agriculture. Various reasons had been given, among them that the sale of cinnamon chips lowered the value of cinnamon and that the middlemen in Mincing Lane had a hand in beating down prices. With this association, and with the co-operation of Mr. de Soysa, whose wealth, and connections in Europe were so well known they would, he thought, be able to arrive at the true cause of the present depression and be able to find some remedy. Apart from those considerations, new products would form an important feature in their transactions, as they must find some new cultivation whereby they should be able to obtain an adequate return for their invested capital in the maritime provinces.

Mr. H. VAN CUYLENBURG seconded and the resolution was passed.

Mr. H. VAN CUYLENBURG proposed and Mr. GABRIEL DE CROOS of Negombo seconded :—

That S. Peter de Soyza, Esq., be appointed Secretary of this Association for the ensuing year dating from 1st proximo.

This was unanimously carried.

Mr. J. MARTIN of Chilaw proposed and Mr. A. O. JOSEPH seconded :—

That the following gentlemen do form the Committee of this Association for the ensuing year with power to take such action as may be conducive to the interests of this Association, viz :—S. Rajapakse, Esq., S. R. De Fonseka, Esq., Jeronis Pieris, Esq., Francis Beven, Esq., S. Tambeyah, Esq., Jacob De Mell, Esq., F. Schrader, Esq., J. F. Drieberg, Esq.,G. W. Stork, Esq., Dr. W. G. Vandort, C. Brito, Esq., P. Coomara Swamy, Esq., Hector Van Cuylenburg, Esq., F. C. Loos, Esq., C. E. De Bread, Esq., Dr. P. H. VanCuylenburg, Simon Perera, Esq., John Clovis De Silva, Esq., S. C. Fernando, Esq., A. de Lowe, Esq., Gate Mudaliyar, Arnolis Dias, Esq., J. Wright, Esq., Louis Pieris, Esq., S. R. Fonseka, Esq., Jr., Juan De Silva, Esq., Mudaliyar, Gabriel Croos, Esq., Jusey De Silva, Esq., and Simon Fernando, Esq.

This was unanimously adopted.

Mr. S. R. DE FONSEKA, in moving the resolution VIII., spoke as follows :—Mr. Chairman and Gentlemen,—I have great pleasure in moving the Resolution VIII. As a cinnamon grower on a small scale, I also have shared, with those like our worthy Chairman and others, the losses consequent on a fall in the prices of cinnamon which, as you are aware, now hardly leaves a profit on the outlay. I have been regularly shipping for some years past my cinnamon to my agents in London, Messrs. Blyth, Green Jordin & Co., and they, in communicating to me the result of the February sales of my consignments, wrote as follows :—"We regret to report that, with a large quantity of cinnamon brought forward, the market was dull, and prices somewhat lower." Again in informing me of the result of the May sales, they wrote as follows :—"At this sale we had to compete with a large quantity of cinnamon, and prices were lower in consequence." I am inclined to think that the large quantity of cinnamon here referred to, is meant to be chips. A friend of mine, whose absence on this occasion is unavoidable, writes :—"I am afraid I shall not be able to attend the meeting on Saturday next, much as I should wish to be present. I have felt, how little we Ceylonese recognize the truth that unity is strength, and I hail the formation of a Low-country Products Association, as a first step towards combined action in the protection of our common interests." This gentleman has been at some pains to point out, how the trade in chips has contributed towards the fall in the prices of cinnamon, and I must candidly admit that the perusal of his recent appeal to all cinnamon planters, which appeared in the press, some time ago, induced me and the worthy chairman too, to rouse ourselves from the carelessness of our own individual interests, and to work up a course in which the will of all concerned to co-operate with each other may at once be set on foot, and for which purpose this Association is intended. I am exceedingly glad to see such a crowded house, indicating as it does that the natives of this island, although improperly characterized, in a certain quarter, as apathetic, are sufficiently alive to their interests, and are not backward in anything of importance to themselves and their country ; and, now that we have such a willing and powerful leader as our worthy Chairman, we cannot fail to succeed in the steps which are to be initiated this day, to avert the losses which attend our trade; I hope therefore, gentlemen, that one and all of you, who are interested in the cultivation and sale of cinnamon, will gladly adopt the resolution :—

That the Committee appointed today do take into consideration the question of the large exportation of chips that is now being made and which this meeting believes has materially contributed to the fall in prices of cinnamon and report on this subject to a general meeting of this Association on a day hereafter to be named. That the wages now paid to peelers and other kindred subjects do also form the subject of this report.

Mr. J. F. DRIEBERG seconded.

Mr. H. L. DANIEL moved, and Mr. R. SCHRADER seconded :—

That the thanks of this meeting be given to the Chairman for his obliging conduct in the chair.

This was cordially adopted, and the meeting terminated.

TEA IN AUSTRALIA: THE DUTY OF 3D. PER LB. IN VICTORIA TO BE ABOLISHED.

In publishing the following letter from our correspondent, we can scarcely agree with him as to the effect of the abolition of the duty. The superior quality of the Indian and Ceylon teas will still lead to a preference for them, and there will certainly be a largely increased consumption :—

Melbourne, 15th June 1882.

The proposal of the Treasurer to abolish the duty on tea has taken the Melbourne public by surprize. Sir Bryan O'Loghlen announced this decision in Parliament on 30th May in the following terms :—

"The Government further propose to sweep away absolutely the duty on tea (3d per lb.) : that duty brings in an income of £100,000 per annum. I apprehend that in this matter the Government will have the support of the whole House, and of the whole colony. The proposition is this :—The full duty should be paid during the first three months of the financial year ; that for the next three months it should be reduced to 2d and for the next three months to 1d per lb. It practically comes to this that in 9 months the duty will be entirely abolished."

£1 per ton a nominal fee will be charged for examination, &c.

In this from such a measure would clearly interfere with trade, and the Government must soon have seen this, for two nights afterwards the Treasurer came down to the House with a fresh proposition, viz. to remit the duty absolutely on the 1st January next, and in this form there seems to be some probability of it being carried.

On the 30th of May the Syndicate had another successful sale by auction of Indian teas, the lot this time

being small, but the whole 945 half-chests passed the hammer rapidly amidst very brisk biddings :—

Assam Pekoes realized from	1s 5½d	₱ lb to 1s 5¾d	₱ lb
,, Pekoe Souchongs	,, 1s 2½d	,, to 1s 5½d	,,
Cachar Pekoes	,, 1s 5 d	,, to 1s 10 d	,,
,, Peokoe Souchongs	,, 1s 2½d	,, to 1s 4¾d	,,
Other Sorts realized	,, 1s 1¼d	,, to 1s 4 d	,,

No fine teas offered.

The season has now very nearly closed, and over 700,000 lb. weight of Indian tea has been sold by auction alone, in Melbourne, at steadily increasing rates. Exclusive of the above and through the same medium, Ceylon gives a total of about 51,000 lb say = total 751,000

Sales privately about Indian 175,000 } 190,000
Ceylon 15,000 }

941,000

a very respectable total for the colony of Victoria to take, and no doubt, if supplies come forward nearly double, they could have been sold, owing to the inferior quality of China teas this season.

THE CULTIVATION OF CINCHONA IN THE NORTHERN AUSTRALIAN TERRITORY.

The following letter has been addressed to the editor of the Melbourne *Argus* :—

Sir,—Since writing you a few days ago, *in re* the cultivation of cinchona (not chinchona) in the Northern Territory of Australia, I have received so many communications from gentlemen who are apparently interested in the subject of the cultivation of tropical plants in Australia, that I am of sheer necessity obliged to trespass on your indulgence in again seeking for a small space in your paper. The subject is, however, one of no small importance to your country, and, if any words of mine appearing in your columns should ultimately tend to the introduction and successful establishment of such industries as the cultivation of coffee, cinchona, cocoa, Indiarubber, and a multitude of other plants not indigenous to Australia, you will, I think, agree with me that your space has not been recklessly or unprofitably loaned.

I now markedly and publicly assert that it is my unqualified opinion that there is an immense area in Northern Australia well suited to the successful cultivation of a large number of tropical products. I do so without fear of contradiction. I speak after 20 years' experience in Ceylon, after several months' of travel and careful investigation in North Australia and therefore with some authority.

For the benefit and information of those who have addressed me, and whom I care not to answer individually, will you permit me to reiterate with all possible emphasis that I have no hesitation whatever in asserting that a large number of tropical products would thrive eminently well in Northern Australia.

In the wise selection of suitable varieties, judgment and experience will have to be brought to bear, but the same conditions exist to successful enterprize in this line in any country.

There are tracts of land there so pre-eminently suited to the growth of cinchona that, if the day ever comes when it shall be your pleasureable duty to report that Mr. Blank realized off his cinchona property bark sales to the value of £1,000 per acre, I, for one, shall not be surprized.

That this will be an immense success I am sure, the only drawback at present being the want of cheap and suitable labour. This is only a matter for Governmental arrangement. There are thousands of men ready to come, if you will only allow them to do so, and I think that matters are now in a fair vein to end in a speedy and satisfactory settlement of this very important question.

It does not suit my purpose at present to enter publicly into particulars with the view of verifying any statements I have made or opinions I have volunteered, but I make them as a practical planter after 20 years' experience, and as one whose utterances in Ceylon on the subject of new products have been publicly made and favourably received.—Yours, &c.,

May 17th. HENRY PʼOETT.

THE EXTRACTION OF ALKALOIDS FROM CINCHONA BARK.

From the Government of Madras we have received a very important and interesting paper, recording the results of experiments made in England in the extraction of the alkaloids from crown and red barks on account of Government. Two experiments were made, and in both the results obtained from crown bark shewed a considerable profit to Government over the prices at which similar barks sold. But in both experiments the crown bark was treated after the fashion usual in the laboratories of chemists specially devoted to the extraction of alkaloids from cinchona bark : that is, so as to obtain each alkaloid—quinine, cinchonidine, &c.—in a separate form. The case was different with the red bark. In the first experiment with this description of bark, the process adopted was one for obtaining "quinetum," or the alkaloids in a mixed form. The result was, in this case, a loss of 10 per cent as compared with the prices which similar bark realized in the market, whether purchased by druggists for use in decoctions or to be worked up by such foreign chemists as lay themselves out to extract the separate alkaloids from red bark. In the second experiments the process for mixed alkaloids was abandoned, and, although the bark now operated on for the extraction of the separate alkaloids was of poorer quality than the previous lot, the result was a profit equal to 10¾ per cent instead of a loss of 10 per cent. The difference between a process directed to the precipitation of the mixed alkaloids, therefore, and the usual scientific methods of extracting the alkaloids in a separate form, was no less than 20 per cent. This was in the laboratory of an experienced London chemist. In Java and in India, it is believed that only 50 per cent of the alkaloids present in the bark is obtained by the necessarily less perfect processes pursued to obtain the alkaloids in a mixed form. It is not wonderful, therefore, that there should be a recommendation to abandon, both in India and Europe, the imperfect method of working for mixed alkaloids, in favour of the strictly scientific process of fully exhausting the bark of what it may contain of each separate alkaloid. The value of the sulphate of quinine alone extracted from red bark in the second experiment was more than the price at which the bark would have sold for, and if Dr. King's calculation is adopted and only the actual cost to the Government taken into account, instead of the market value of the bark, sulphate of quinine extracted in London will compete in cheapness with the mixed alkaloids obtained in the British Sikkim factory. Those mixed alkaloids are chiefly the inferior and much cheaper ones, cinchonidine and

cinchonine, and, while the efficacy of the mixture seems beyond a doubt, Mr. Howard still dwells on its nauseating effects. Dr. King, our readers are aware, insists upon it that nausea only occurs when, under a mistaken impression as to its inferior potency, over-large doses of the mixture are administered. We may take it for granted that Dr. King and Mr. Gammie will have something to say to results, on which a recommendation is based that the extraction of alkaloids in a mixed form should be abandoned and expenditure on a factory in India avoided. Extensive experiments with Darjiling bark are recommended, and meantime for the result of those on Nilgiri bark it is claimed that, after payment of freight, charges and the cost of extraction by a competent chemist like Mr. Whiffen, the gain to Government as compared with selling the bark in the open market is 23 per cent in the case of the crown barks and 10⅝ per cent in that of the red barks. We believe it is admitted even by Dr. King and Mr. Gammie that about 2 per cent of the alkaloids in the red bark are lost in the process of precipitation and purification in use in British Sikkim. Taking the average of alkaloids in red bark at 6 per cent, this would represent a loss of 33⅓ per cent, or one-third, instead of Mr. Moens' 50 per cent, or one-half. Still the loss of one-third of substances so valuable is a loss not only to Government but to the world, and we cannot wonder that, after adverting to the alleged ancient and imperfect method of extracting quinine adopted by Mr. Gammie, the final conclusion should be that it may be cheaper to send the bark to England, where not only can the quinine be better made but "the full amount of the alkaloids obtained."

We have thus indicated the main results of the experiments to which this official paper (which will be given in full in the *Tropical Agriculturist*) refers. But incidentally we obtain some curious and interesting information as to the relative values of cinchona barks in their natural state, mossed and renewed. We see that of sulphate of quinine, crown bark renewed yielded from 5·57 to 5·73 per cent, against 4·38 to 5·06 in the case of mossed bark and only 3·30 to 3·87 for natural bark. The best result of natural bark, therefore, in this the most valuable constituent, was 1·86 per cent under the best for renewed and 1·19 worse than the best result of mossed bark. In the renewed bark sulphate of quinine largely displaces the inferior alkaloids, for the renewed bark which gave 5·73 of quinine sulphate gave only 0·66 of cinchonidine sulphate and 0·21 of cinchonine alkaloid. The effect of mossing, as seen here, is different: it increases the amount not only of quinine but also of the other alkaloids: for the best result in the case of mossed bark shews not only 5·06 of quinine but 1·52 of cinchonidine, the next best alkaloid. All this as regards crown bark (*C. officinalis*). In the case of red bark, we have no renewed, but it will be seen that the effect of mossing was very largely to increase *all* the alkaloids: 1·74 instead of 1·23 quinine, 5·24 instead of 2·97 cinchonidine, and 2·20 instead of 1·24 cinchonine. If, therefore, the bark in its natural state (its cultivated state, rather) is good, we have a right to characterize mossed bark as better and renewed bark as best. Altogether we may regard the paper under notice as not the least important of the contributions to the literature and science of the cinchonas, which we owe to the Government of Madras.

QUININE.

The following is from the New York *Oil and Drug News*, and allowance must therefore be made for the point of view of manufacturers in saying that the demand for quinine and bark is not at present likely to increase:—

THE POSITION OF QUININE.

The bark syndicate in London have now had virtual control of the bark market there for the past six months, and, although speculative operators in quinine at first made the most of the position, and speculated on the probability of a permanent control by the London syndicate of the world's supply, there has been a gradual falling-off in the price of quinine, even the recent attempt to bolster up the price by shipping a part of our surplus back to England failing to bring about the reaction expected. It is true the market for German advanced about ten cents per ounce following this exportation, but this is entirely due to speculative operations, the supply here being considerably reduced and giving holders an opportunity to control it. But the actual position is not materially changed, the actual demand for consumption not warranting the large quantities held here prior to the return of the 45,000 ounces to England. The efforts of the London syndicate to advance the price of quinine and to keep it up have been persistent, but they have met with determined opposition by the manufacturers in this country at least, and the sales of bark at London show that the earlier reports that the manufacturers of quinine in England and on the Continent were in league with the bark syndicate had no foundation in fact, it being evident that the manufacturers are and have been purchasing only as their more urgent needs made imperatively necessary. Furthermore, it is evident from the small quantities recently sold, being only about twelve per cent of the whole lot offered, that the European manufacturers have been able to draw a large part of their supplies from other sources, probably direct from the places of production. This is exactly the contingency that we pointed out the bark syndicate would have to meet, when writing on this subject last December. At that time the total visible supply of bark was estimated at 100,000 bales, equivalent to about two and a quarter million ounces of quinine, and if, as is now asserted, the supply has diminished, there is still sufficient on hand for a year's consumption. Add to this the large surplus of the manufactured product, and we cannot see how the position is any more favorable to the syndicate than it was six months ago.

An increased consumption of quinine had been looked for this spring as compared with any preceding corresponding season, but the fact is the demand for consumption is not so large as it was a year ago, and there are now no indications that any important increase in the consumption will set in, although the spring has been rather unseasonable and not conducive to robust health. The inundations caused by the rise of the Mississippi river were counted on later as creating an increased need for this article, but as the waters subsided there was no such increase developed, and even this source of demand was not realized. In fact, every point predicated as calculated to improve the position of the syndicate and the speculative holders has failed them, and now that, by shipping a part of our surplus back to England, and the comparative firmness of the markets there, an advance has been gained, there is still nothing in the condition of the article at present to warrant

the expectation of a permanent enhancement of prices. In this view of the situation we are not alone, as is evidenced by the caution of buyers. At the prices now asked by holders of German there is little encouragement to purchase for speculative purposes, although some fair sales have been made during the past week, probably to fill contracts of parties who had sold "short." The pretty general belief entertained in the trade that American manufacturers would advance their prices, following the slight reaction in German, has not been confirmed, they doubtless seeing the situation did not warrant the rosy view taken by some of the more sanguine speculators, and being less influenced by the temporary flurries in this market.

PLANTING IN THE NORTHERN AUSTRALIAN TERRITORY.

(FROM THE "ARGUS" SPECIAL REPORTER.)

AGRICULTURAL AND PASTORAL :—These two industries are yet in their early infancy. On the first, not more than £25,000 has been spent throughout the Territory ; and on the second, leaving the price of cattle out of the question, not so much. But the results obtained, in agriculturre especially, where they are sooner measurable, have been encouraging out of all proportion to the effort, personal or pecuniary, expended.

I will first briefly indicate what has been done in furtherance of it. The most important place, agriculturally, and that which served as a nursery for all the rest, is the Government plantation at Fannil Bay, about four miles from Palmerston, and on the coast. Years ago there was another Government garden close to the town, but very little real work was done in it. It is only two and a half years ago since the present plantation, the area of which is 32 acres, was selected and cleared, but during that time a thousand different kinds of Chinese and other tropical plants have been tried—nearly all successfully. The white ants, that at one time seemed an insuperable bar to the cultivation of acclimatized vegetation in the territory, have been overcome by the use of arsenic, and, though there has been only one skilled man to supervise the work which Chinamen, paid from 15s to 20s a week, do, the garden scientifically and practically is all that one could wish to see it. Though the ground was chosen because of its second-rate character, the better to test the average of the soil throughout the Territory, and, though not a spadeful of manure or a drop of water besides that falling directly from the clouds have been used the area is covered with luxuriant plants, many of them aspiring above the heads of outside native trees, perhaps 50 times as old. Creepers indigenoeus to a foreign soil, planted here, have run at once over the place, and now grow everywhere in wild profusion.

Of sugar-cane there are 16 acres flourishing. From the last year's crop was made at Delissaville the first sugar ever manufactured in South Australia—a sugar equal to the ordinary imported table kinds. Maize is the next principal crop in the garden, and it is looking as well as it can look anywhere, notwithstanding that it is the third crop in a year. Rice simply flourishes, strengthening the evidence I have had throughout that the Northern Territory will be a great rice-growing country. Cinchona has not been so successful as it was expected it would be, but young plants in the interior look strong enough. The test will be, of course, when they get bigger. Coffee does not do well in the gardens. The prime cause is said to be the fact of its being planted so near the sea. The Arabica is not unhealthy looking above ground but it has no root. The Liberian looks sturdy, but needs great care and attention. Tea and several spices have failed to grow satisfactorily ; cocoa is moderately successful. I saw young tobacco plants with leaves 27in. long by 18in. wide. From these capital cigars have been made. One of the best things in the gardens is arrowroot, which actually overruns the place, growing in grand perfection weed-like. Some of the roots, ground with a nutmeg-grater, yielded a compound declared by the local importers to be superior to the common article of import. An average of the productiveness of the crop was based on this return, proving that even the indifferent soil in the gardens will yield at least 25 cwt. of the finest arrowroot per acre. Cotton grows wild all over the place. The same may be said of indigo, the plants of which grow 5ft. high. Peanuts thrive ; last year one-fifteenth of an acre gave 4 cwt. The chief of the other plants which have been successful I will simply enumerate promiscuously, with the mere mention of the fact :—Pine-apples, bananas, plantains, Scotch kale, pepper, cloves, capsicums, chilis, cinnamon, lychee-nuts, mangoes, bread-fruit, guava, jack fruit, yams, melons, beans, sweet potatoes, Manilla almonds, mandarin oranges, lemons, citrons, pomegranates, Cape gooseberries, custard apples, carob beans, figs, earthnuts, sorghum, sesamoil, cassava, castor oil, sweet sob and sour sob, rhea, or Chinese grass plant ; Indiarubber, teal (Chinese oil plant), several fibre plants, including the bamboo silk, the Indian physic nut, the papaw, and scores of others.

In the open ground and in a special shade bamboo nursery, various kinds of grasses have been tried. The best to succeed is the common Phillips's, though several of the Alizanas also thrive. The English lawn grass grows well under shade, but does not seem to stand the heat, and the gardener's experience has taught him that the native grasses are just as good as the imported are in their own home, and better than they ever will be in the Territory. He has experimented with the tall rank kinds I referred to in my telegrams, and by cutting them down frequently he has got at last a thick, soft, fast-spreading, somewhat dwarfed buffalo grass, which surpasses the best "couch" for lawn and feeding purposes. English lucerne grows well, and the reana, a luxuriant fodder plant about 15ft. high, springs up with surprizing rapidity.

The gardens were formed for the "express purpose of raising plants of commercial value, and distributing them over the country." In pursuance of this object, seeds of the best acclimatized grasses are offered to the teamsters for distribution around the camping-grounds in the interior. Last year 140 tons of cane-heads were given to plantation owners for planting. During the same time 8,000 banana trees and 13,000 pineapple plants were distributed gratuitously, and this season the figures are already 2,000 and 5,000 respectively. In every sense the plantation may fairly be classed amongst the most successful experimental works tried by the South Australian Government.

In referring to private plantations, all of which I visited, I would preface my remarks with the observation that the industry was pioneered by Chinese, who have for years warded off disease in the mining districts in the interior by dispensing to the European diggers the vegetables they grew. There are scores of these small gardens all through the country and Companies are to be formed in Hongkong to take up large areas of plantation land, to be owned, managed, and worked solely by Chinese. Rice and sugar, and possibly the opium poppy, are to be the staples of the crops, and the industry will probably embrace the manufacture of "samshoo," or Chinese wine. All the work on the English plantations is being done by the Chinese, whose wages, "finding themselves," are £1 a week. Some of the plantation owners prefer them to European workmen.

Of these plantations, the principal is Delissaville, about 11 miles from Palmerston across the harbour (a grand harbour by the way) and on Douglas's Peninsula. The area is 10,000 acres, and the block is part of 70,000 acres given away by the South Australian Government under the Sugar Grant Act, to encourage cultivation. By a subsequent legislative blunder, however, the effect of the general legislation on the subject is to encourage land speculation rather than a more legitimate enterprize. At any rate, the cultivation which has resulted is very far below what expectation pictured it. Only two of the blocks have had anything whatever done upon them. An expenditure of £16,000 has been incurred upon Delissaville, which has 200 acres of sugar-cane and about 70 of maize, the latter more satisfactory in appearance than the former, though this fact is easily accounted for by the circumstances apart altogether from conditions of climate or soil. A thoroughly well-appointed mill, costing £10,000 with the enclosing buildings, has a prominent position upon the ground. This is the only sugar-mill in South Australia, and it will be noted hereafter as that whence the first sugar manufactured in the colony came.

On the Daly River, sugar and maize planting has been begun by a Melbourne Company, under the name of Messrs. Petersen, Croston & Spence, on 20,000 acres, the gift of the Government. They have 20 acres of canes in a nursery, thriving much better than those at Delissaville, and a small acreage of maize. They intend to plant a large area from the nursery, and to crush in 1884, by which time they expect to have a mill erected.

By another Melbourne Company, under the name of Poett and Mackinnon, there has been started near Rumjungle, on 3,400 acres of the best soil in the Territory, a coffee plantation, which had not at the time of my visit been applied to its original purpose. But this, I should explain, was not the fault of the proprietary. Awaiting the arrival of seeds from Ceylon, they are trying cinchona, which was just springing vigorously above the ground. They are going to grow maize also.

This exhausts the list of plantations on which actual work has been done, though several new ones are being started in time for the next season. On the Adelaide river alone 70 800 acres are protected by special survey applications for sugar-growing; 21,000 acres in the Hundred of Bagot north of Palmerston; and 2,000 acres on Douglas Peninsula, besides the 70,000 herein-before written of. In the Hundred of Ayers, 3,000 acres is held for plantation purposes, and near the coffee plantation at Rumjungle, over a wide radius, to all the land the same remark applies, as it does also to a great deal of that surrounding the harbour, particularly near Southport. The purely experimental work has been already done. The planters now can avail themselves of certain knowledge where two years ago all was uncertainty. The only trial has been thoroughly successful, and the logical conclusion is that the success will be generally as experiments multiply.

NILGIRI CINCHONA BARK: EXTRACTION OF ALKALOIDS IN ENGLAND.

Government of Madras; Revenue Department. Read: the following despatch from the most honorable Marquis of Hartington, Her Majesty's Secretary of State for India, to His Excellency the Right Honorable the Governor-in-Council, Fort St. George, dated India Office, London, 30th March 1882, No. 16 (Revenue).

Referring to my Despatch, No. 14. of the 18th May last, I now enclose, for Your Excellency's information, a copy of a memorandum, showing the results of the manufacture of cinchona alkaloids from the 250 bales of crown and red barks, which formed part of the consignment received from your Goverument per steamship "Eldorado."

ENCLOSURE.—*Report on the Manufacture of Sulphate of Quinine and other cinchona alkaloids on Government account, dated 18th October 1881.*

Last year an experiment was made of manufacturing sulphate of quinine and other alkaloids, on Government account, from the bark sent home from the Nilgiri Government plantations. The result of this was so far satisfactory that it was determined to repeat the experiment on a larger scale. The manufacture of the several alkaloids from the crown and renewed barks yielded financially, 14 per cent more in the value of the products than the bark operated upon would have realized, if sold in the open market in the usual manner. With the red barks it was different, and the result in the case of these was a slight loss. In the former experiment, mixed alkaloids were extracted from the red barks, the value of which was found to be almost exactly 10 per cent less than the bark itself would have fetched, if it had been sold.

For the purpose of further experimental manufacture, 250 bales,* forming part of the consignment received per steamship "Eldorado" last February, were made over to Mr. Whiffen, samples having been first taken for analysis on behalf of the Secretary of State by Dr. B. Paul, whose report gave the following results:—

	Bales.	Quinine, Sulphate. per cent.	Cinchonidine, Sulphate. per cent.	Cinchonine (Alkaloid.) per cent.

The result of the working of these barks has been as follows :—

	200 bales of Crown Bark.	50 Bales of Red Bark.	Total.
	lb.	lb.	lb.
Sulphate of quinine ...	1,045·5	81·5	1,127
„ of cinchonidine ...	149·5	143	292·5
„ of quinidine ...	25	—	25
Cinchonidine alkaloid ...	71·25	71	142·25
Amorphous sulph. liquor ...	404	240	644

From the foregoing figures, it will be seen that, as, on the former occasion, the yield of sulphate of quinine has been in excess of the estimated result, and the sulphate of cinchonidine obtained somewhat under the expected yield, but the cinchonine alkaloid shows a slight excess. The sulphate of quinine shows an excess of 115·74 lb., or over 11 per cent. So far as the outturn is concerned, the result is therefore satisfactory.

With regard to the financial results of the experiment, it appears from Messrs. Jenkins' and Phillip's report of their sale that the average prices realized from the sale by public auction of similar parcels of bark forming part of the same consignment, were—natural crown, 5*s* 8*d*; renewed crown, 8*s* 11*d*; mossed crown, 10 bales at 6*s* 10*d* and 35 bales at 6*s*; branch crown, 3*s* 4*d*; natural red, 2*s* 5*d*; mossed red, 3*s*. At these prices the value of the above-mentioned barks was as follows :—

	LB.	s.	d.	£	s.	d.

					699 13 6
			Total ...		£8,635 19 3

From these figures it will be seen that the total net value of the products obtained from the bark is 8,635*l* 19*s* 3*d* as compared with 7,080*l* 9*s* 10*d* which would have been realized for the bark, if it had been sold with the remainder of the consignment of which it formed a part. The net gain by manufacturing on account of Government instead of selling the bark has thus been 1,555*l* 9*s* 5*d* or nearly 22 per cent. Similarly, it will be seen that the net gain in respect of the crown barks alone is 23 per cent and in respect of the red barks nearly 10¾ per cent. These results are obtained by taking, for the purpose of calculation, the price of quinine in May last, the date when the manufacture had been completed and the products were ready for delivery. The result of this experiment is considerably more satisfactory from a financial point of view than the previous one, which showed a net gain of only 9 per cent more than would have been realized had the bark been sold in the usual manner. It may be a question for consideration whether in future it will be advisable to work up the quinoidine into liquor unless it can be shown that there is likely to be any demand for it. A preferable plan probably would be merely to precipitate the alkaloid and not purify it, but set it aside in its rough state till such time as some use may be discovered for it. In the foregoing calculations, I have taken the value of it at merely the cost of manufacture, viz., 1s per lb.

As on the former occasion, the gain is chiefly obtained from the crown barks. In the previous experiment, the products from the red barks were obtained in the form of mixed alkaloids, and this resulted in a loss of 10 per cent. in value as compared with what would have been obtained by the sale of the bark. I then suggested that "it might, perhaps, be found more advantageous, from a pecuniary point of view, to extract the several alkaloids separately from the red bark instead of making cinchona febrifuge." The result has quite fulfilled my anticipations, for it will be seen from the foregoing figures that the value of the alkaloids separately extracted is 699*l* 13*s* 6*d*, taking the price at 163*s*, as compared with about 632*l*, the net price which would have been obtained for the bark if sold, showing a gain as already stated of nearly 10¾ per cent, instead of a loss of 10 per cent., notwithstanding that the red barks used in this experiment were very considerably poorer in quinine sulphate than those operated upon on the former occasion. It may also be noticed that the value of the sulphate of quinine alone extracted from the red bark amounted to more than the bark would have sold for.

This alteration of the mode of dealing with the red bark is the most important part of the present experiment, and deserves further examination. In the former experiment 4,277 lb of red bark, of a net value of 596*l*

* Including a proportion of 21*l* paid for fire insurance at factory.

2*s* 2*d*, yielded mixed alkaloids of the value of 666*l* 7*s*, the cost of manufacturing which was 130*l*, or a little less than 20 per cent. of the total value. On the present occasion 5,104 lb. of bark, of the net value of about 632*l*, yield separate alkaloids of the gross value of 972*l* 11s 6*d*, and the cost of their production was 272*l* 18s, or a little over 28 per cent. In other words, by a process of manufacture 8 per cent. more expensive, a yield is obtained over 20 per cent. of increased value. This result seems calculated to throw some doubt upon the economic value of manufacturing quinine, and it is submitted that it might be desirable to make an experiment in this country on a tolerably large scale, with bark from the Darjiling plantation, before the Government of India commits itself to any considerable expenditure in the erection of a factory for the manufacture of quinine or quinetum in India.

Hitherto the results of these experiments have been considered from a purely financial point of view. It must, however, not be forgotten that, as has been expressly declared on more than one occasion, the object of the introduction of the cinchona plant into India was in order to place within the reach of the masses of the people, at the lowest possible rates, the only effective specific that science has yet discovered for the commonest of Indian diseases.

Adopting this view, the Bengal Government calculate the price of their cinchona febrifuge at its actual cost to the State, which in 1880-81 was R9-3-10·625 per lb., which is made up as follows :—

	RS.	A.	P.
Price of bark used in making 1 lb. of febrifuge	6	4	0·760
Cost of manufacture, tinning, advertizing, &c.	2	15	9·865
Total ...	9	3	10·625

which, at 1*s* 8½*d* the rupee, is equivalent to 15*s* 9·7*d* per lb. Adopting a similar process of calculation for the Madras bark, the following result is obtained :—

	£	s.	d.
* Cost of 50 bales (5,104 lb.) of red bark	259	10	8
Freight, wharf charges, &c.	30	6	8
Return freight, &c., say	27	4	8
Total ...	317	2	0

The cost price of the several drugs delivered to the Government of India would thus be—

	LB.	Cost of Manufacturing Bark, &c.	Charges, &c.		Total.	Rate ₹ lb.
		£. s. d.	s.		£.	£ s. d.
Sulphate of quin.	81·5	242 13 0	24	per lb.=	97·15	340·8 83 6
,, of cinchonidine	...143	50 12 0	18	,,	=128·14	179·6 25 0
Cinchonine alkaloid ...	... 71	22 6 0	8	,,	= 28·8	50·14 14 0
Amorphous sulphurons liquor	... 240	1 11 0	1	,,	= 12·0	13·11 1 1½
		317 2 0				

* The total charge against the plantations including interest on balance for 1879-80, the last year for which a report has been received, was R1 06,763-9-7, and the amount of the harvest was equivalent to 179,299 lb. of dry bark, the cost of which was therefore 9 annas 6·3 pies per lb., at which rate 5,104 lb. would cost R3,038-7-7, or £259 10s 8d.

In the same way it may be shown that the sulphate of quinine manufactured from the crown barks will be delivered to Government in India at a cost of only about 40s 7½d per lb., at which price it will successfully compete with the Sikkim febrifuge.

A second collection of papers, showing the recent result of the trial of cinchona febrifuge and other alkaloids prepared in Bengal from the Sikkim bark, has recently been received from India. Copies of these were sent to Dr. Macnamara and to Mr. J. E. Howard for report. The former notices that, "the cinchona febrifuge manufactured in India from red bark has evidently maintained and, indeed, increased its reputation," and he urges "that the Government factory be placed in a position to produce the febrifuge in such a quantity and at so low a price as will provide for its widespread employment." Mr. Howard, on the other hand, points out the inferior efficacy and cheapness of sulphate of cinchonine and of sulphate of cinchonidine. He remarks that, in these papers, the febrifuge seems generally admitted "to be a nauseous medicine detrimental in a greater or less degree alike to Europeans and to natives. . . . Apart from these effects the efficacy of the remedy seems to be universally admitted, being apparently that of cinchonidine and cinchonine, of which it is chiefly composed." Mr. Howard notices that the amount of febrifuge obtained falls very far short of what is to be expected if the bark were thoroughly exhaussed, and he quotes a report by Mr. Moens, in which it is stated that, "in the analytical laboratory of the Medical Department, by Dr. De Vrij's method (so-called), out of 3,000 kilograms of dry bark 56 kilograms of quinetum were prepared, less than 50 per cent of the alkaloid that was present in the bark." Should the Indian Government have any serious intention of improving the alkaloid, Mr. Howard says he should be happy, if desired, to supply further suggestions.

With their letter, No. 26 of 1881, the Government of India forwarded particulars of the process adopted by Mr. Gammie for the manufacture of sulphate of quinine. There is nothing new in this process, indeed it is a very old one which may have been employed in this country, but has certainly been abandoned for improved methods of manufacture for more than a quarter of a century, as it would be impossible by its use to extract the whole of the alkaloids from the bark. But probably this fact has already been ascertained by Mr. Gammie, and that he will be able to introduce some more efficient process of manufacture, before recommending Government to incur expenditure with a view to carrying out the manufacture on an extensive scale.

It may, however, be a question for consideration whether it would not be cheaper to send the bark to England for manufacture, where it would certainly be better made than in India, and the full amount of the alkaloids obtained, instead of permitting half of them to be lost, as is at present the case.

COFFEE IN BRAZIL AND THE PROSPECTS OF THE COFFEE MARKET.

The exports of coffee from the two great ports of Brazil from 1st July to 30th April (10 months) were, recording to Kern, Hayn & Co.'s report :—

	1879-80.	1880-81.	1881-82.
From Rio ...	152,730 ...	197,028 ...	182,954 tons
,, Santos ...	52,962 ...	58,358 ..	75,141 ,,
Total ...	205,692 ..	255,386 ...	258,095 tons

There has thus been an increase in Rio for the 10 months of the present season over 1879-80 of over 30,000 tons, while Santos shews an increase, much greater in proportion, of 23,000 tons. Compared with the immediately previous year, there is a falling-off from Rio of 15,000 tons and an increase from Santos of 17,000 tons. If exports went on at the same rate for the two months ending today, the total for season 1881-82 will be : For Rio 213,500 tons

Santos 87,500 ,,

Total 301,000 ,, or 6,020,000 cwt.

A few years ago the average export was 200,000

tons or 4,000,000 cwt; or less by 101,000 tons the equivalent of 2,020,000 cwt; the usual calculation being total crop 260,000 tons, of which 200,000 were available for export, the rest being locally consumed. At present the total crop must be close on 400,000 tons or 8,000,000 cwt.: considerably over the quantity grown in all the rest of the world. Messrs. Kern, Hayn & Co. at the end of April took the view that the total exports from Santos would reach from 1,600,000 to 1,700 000 bags: if indeed the latter figures were not exceeded. Messrs. Robert von Glehn & Sons in their London Circular of 9th June (by which time the telegraph had enabled them to anticipate the results of the Brazil season ending this day) take a different view and hold that, while the deficiency of Rio exports to Europe will be 500,000 bags as compared with last year, the excess in Santos kinds (which go nearly all to Europe) will be only 300,000 bags. There will, therefore, if these calculations are borne out, be a total deficiency of 200,000 bags in the exports of Brazil coffee to Europe as compared with season 1880-81. To a deficiency in arrivals from Brazil is attributed "a good general demand at advancing prices for coffee" during the month of May. Including the shipments in May, advised by telegraph, the total exports from Rio, to America and other places as well as Europe, are not expected to exceed 4,000,000 bags, against 4,361,000 in the previous season. To Europe, as has been already shewn, the exports in 1881-82 were less by 500,000 bags than in 1880-81, the Rio coffee being diverted to the better markets for this kind in the United States. In the face of Messrs. Kern, Hayn & Co.'s higher estimates, Messrs. von Glehn & Sons quote figures which make the total shipments from Santos for 11 months only 1,370,859 bags, so that they do not expect a total of more than 1,500,000 bags. If their estimate is correct, so much the better for Ceylon coffee, with which Santos kinds seriously compete. For this superior coffee the market in the United States is so limited that about 200,000 bags only out of the 1½ million from Santos are diverted from the European markets. While thus giving the figures for Brazil exports in the season just closed, Messrs. von Glehn & Sons anticipate that there will be no falling-off in the crop of the season which commences tomorrow. In regard to our own season which commences on 1st October, the case will be very different, and only 10,000 tons=200,000 cwt. of Ceylon coffee are expected to reach the London markets, where the consumption of our fine coffee is not increasing, but the reverse. We shall see what effect short supplies and the new rules as to adulteration have. Both as regards production and prices realized, let us hope that we have now reached the lowest point and that reaction of a beneficial kind may set in.

THE AUSTRALIAN DUTY ON TEA.

TO THE EDITOR OF THE [MELBOURNE] "ARGUS."

SIR,—The proposal of the Government to reduce gradually and finally abolish the duty on tea is most objectionable in its present form.

Taking the financial year to commence on the 1st July next, it means that for a period of 10 months the tea trade of Victoria will be disorganized and seriously interfered with.

Traders and retailers will from this day forth steadily reduce their stock of tea held duty paid, and only draw fresh supplies for daily requirements. Country grocers and storekeepers will suffer most, and find the above plan of working very inconvenient and expensive, and will probably lose the equivalent duty rather than adopt the alternative.

For a week or so before each reduction in duty takes place, very little tea will be held by the bulk of retailers, or cleared at the Customs, because a reduction of 1d amounts to about 6 per cent, 2d to 12 per cent, and 3d to 18 per cent off the cost of the bulk of tea now sold in Victoria, and represents each reduction of duty as it comes into force.

Probably the most feasible plan, and one causing the least inconvenience to all parties, would be to abolish the duty of 3d per lb. on the 1st January, 1883, and this would not alter very materially the present estimates of the Treasurer.

But surely the Treasurer's statement in the House that the "duty on tea brings in an income of £100,000 per annum" is over-estimated, for this shows an increase of 50 per cent over the same period in 1880. The figures stand thus—

Net revenue returns for year ending 30th June, 1880 ... ... £68,540
Do. year ending 30th June, 1881 ... £77,523

No doubt the year 1881-1882 will show a large increase, but scarcely the £22,477 increase as estimated by the Treasurer.—Yours, J. O. MOODY.

Little Collins street west, 31st May.

[£100,000 revenue from duty at 3d per lb. would mean 8,000,000 lb. of tea consumed by a population of 850,000, or nearly 10 lb. per head. That this consumption will speedily be reached, we doubt not.—ED.]

HOW A PLANTER IS TREATED IN FIJI.—We give on the next page the long tale of harsh treatment as Mr. Fillingham Parr tells it, and without holding ourselves responsible for the strong language in which he denounces some of the parties concerned in the annihilation of his coffee and in the subsequent law proceedings. What is stated about Mr. J. R. Hedges and his sayings and doings will prove amusing reading to his friends and acquaintances in Ceylon. As represented, the case certainly seems a very hard one, and we should think the judgment ought to be appealed against to the Privy Council. Altogether they do some things queerly down there in Fiji!

ANALYSIS OF RED BARK SHAVINGS.—A Dimbula planter writes:—

"Possibly, the accompanying analysis by Dr. Paul of a sample of bark from about 1,500 trees might interest some of your readers. The trees were planted in 1877, original shaving February 1881. Shaving of renewed bark, of which analysis is enclosed, March 1882 (being 13 months under moss).

"Analysis of shaving succirubra, renewed mossed, from Pittenweem estate:—

Crystallized quinine sulphate ...	5·23
,, quinindine ,, ...	—
,, cinchonidine ,, ...	3·11
Cinchonine (alkaloid) ...	1·09

(Signed) B. H. PAUL, London."

The interest of this analysis would have been increased, could it have been compared with that of the original shavings. As it stands, though, it is highly satisfactory.

Correspondence.

To the Editor of the Ceylon Observer.

HOW A PLANTER IS TREATED IN FIJI.

Levuka, 22nd May 1882.

SIR,—As I believe the *Ceylon Observer* is the leading planters' journal in the world, I shall be much obliged if you will kindly insert the following letter in it. I have informed Dr. McGregor and Mr. Hedges that I should write to you.

In June 1877 I commenced to open the Great Amalgam estate, which at that time was dense forest, and by the end of 1878 I had 355 acres planted with coffee. The land was selected after much thought and due inspection, and upon the advice at that time of the most experienced coffee planter in Fiji. The lay of the land was as perfect as it could be, and it was very heavily timbered and covered with enormous soft and hard wood trees and looked as though it would grow anything. Mr. J. P. Storck had often been over the place when hunting for specimens, and he says in his opinion the land was everything that could be desired for a coffee plantation. As a matter of fact, some 21 months ago I caused to be sent to Mr. Cochran (Colombo) for analysis a sample of the soil from the surface down to a depth of 3 feet, which analysis Mr. Cochran published in the *Ceylon Observer* with a letter dated 11th October 1880. On reference to that letter it will be observed that he says:—"Upon the whole it is very similar to that of our Ceylon soils. The percentage of lime is low, but higher than most of the Ceylon soils that have been analyzed. The amount of potash is about our average, while the phosphoric acid is higher. The percentage of nitrogen is fair.* * * In making this comparison, however, it is to be remembered that the Ceylon soils analyzed within the last three years have been chiefly, if not exclusively, surface soils," and, as stated in the early part of his letter, the sample he received represented the composition of the soil from the surface to a depth of 3 ft. I am therefore led to the conclusion that with proper cultivation, such as draining, digging, lining, &c., the estate would have become a most valuable property; for the maiden crop on the coffee first planted was, at two years of age, estimated at from 4 to 6 cwt. an acre. As much as 13¾ cwt. an acre have been gathered in Fiji, and 10 and 12 cwt. more than once; and, if estates in Ceylon producing 5 or 6 cwt. are worth as much as £100 an acre, I don't think it unreasonable to imagine that coffee property in Fiji might be equally as valuable when producing double that amount of crop.

In 1879 leaf-disease, almost as a natural consequence of planting coffee, made its appearance in Fiji, and everyone, especially those least acquainted with the disease, appeared to be panic-struck; and Great Amalgam was the place on which it was first *noticed*. I may mention that now scarcely anyone fears the disease in Fiji, and but little damage appears to be done by it.* I was absent in the Australian colonies during the time of the great scare; otherwise I should have hoped to have allayed it. But to prove to what absurdity men, otherwise sane, can commit themselves under similar circumstances, the fact that the Agricultural Society sent a deputation to the Governor, and begged him to burn off the place at once—without first ascertaining whether the disease was on any other plantation, and after several simpletons had carried diseased *leaves* to various islands in the group as specimens—would, if that Society had not since then collapsed through incapacity, have entailed everlasting disgrace upon it; and its then acting members can never otherwise be regarded than as the least practical of men. However after one or two meetings had been held a commission was appointed, whose working members consisted of two young men—one of whom had never *seen* a coffee tree, and the other had merely stayed in Ceylon for a few months as a visitor—to visit and report upon every estate in Fiji; and within a few weeks after they had reported that leaf-disease only existed on Great Amalgam—as soon in fact as a practical man could visit each estate—leaf-disease was reported to exist upon nearly every patch of coffee in the country.

Great Amalgam was opened by, and was in charge of, a Ceylon planter of 10 or 12 years' experience, and the magnificent appearance of the young coffee when in full blossom was the cause of numerous congratulations. Early in 1879 Mr. George P. Drummond (a brother of your Mr. John Drummond), who was then a perfect stranger to me, wrote to me at my request to tell me of the prospects of my plantation. He said:—"In all my planting experience, and that extends over 16 years, I have *never* seen finer or more promising-looking young coffee than that now growing on Great Amalgam &c." Before any definite action was taken by the Agricultural Society the disease was officially reported on other patches of coffee, and nothing was then done until after my return to the colony in September. The Government were very anxious to get my estate into their own hands in order that Dr. McGregor, Chief Medical Officer, might try his hand at experimenting, and see if he could not get rid of the disease. This was partly, I believe, because the natives had grown a little coffee, but principally because Sir Arthur Gordon had such a high opinion of Dr. McGregor's ability that he may have thought it would be a fine chance to shew to Messrs. Abbay and Morris that where they had failed Dr. McGregor had succeeded. I, on the other hand, objected most strenuously to their interfering with so valuable a property, as I felt certain, after the manner of Governments in crown colonies, that sufficient care would not be exercised in the supervision, and that Great Amalgam would be sacrificed. Numerous interviews took place at my office with the Colonial Secretary, the Attorney-General, Dr. McGregor, &c., but I declined to accede to the wish of the Government. Eventually Sir A. Gordon sent Mr. A. J. Stephens (formerly of Ceylon) to me and told me that, if I would agree to their desire, I should receive compensation for the crop of coffee then on the trees, and not be called upon to pay anything towards the cost of experiments; Morris' lime and sulphur treatment—which was then so much talked of in Ceylon—being the only experiment that occurred to either Mr. Stephens or myself. Knowing as I did that anyone in this "crown colony of a severe type" who would not fall in with the wishes of the Governor might at once retire, as his fate could be safely predicted I made a virtue of necessity, and agreed to do what he wished; and, as I knew that Great Amalgam would be benefited by a good liming, I foolishly proposed to pay half the cost of applying it, if the Government were unsuccessful in *stamping out* the disease. I also stipulated that a gentleman should be put in charge in whom I had confidence, and Mr. Stephens was appointed. An agreement was drawn up and executed between the Colonial Secretary and myself in which the Government agreed to endeavour to *stamp out* the disease; to weed, and keep the plantation as free from weeds as it then was; to put in all necessary supplies; before the end of January to properly stake all the coffee; and to cut roads and drains; they also agreed to compensate me for the crop of coffee then on the trees, and, in case of any dispute arising between us, it was to be settled by arbitration in the usual way.

* "Wait-a-bit."—ED.

Up to the time leaf-disease broke out I had always had upwards of 200 permanent labourers on Great Amalgam, but I soon saw from the number Government employed in what manner they were going to carry out their agreement. The agreement itself was not actually signed until the 11th October, but on the 1st October, Dr. McGregor, unknown to me, sent the whole of my labourers off the estate, and put it into quarantine, although the Government labourers were unable to be put on to it until the 18th October, the weeds having thus all this time to get a firm hold. I ought to mention that on the 1st October it was all but impossible to discover a weed on any part of the estate, and that I have never lived on the plantation, but in Levuka, which is on another island and 40 miles distant. On the 18th October *fifty* coolies were sent by the Government on to Great Amalgam, and until the 15th January 1880 this was their full force; it will be readily seen therefore how utterly impossible it was for them with so few hands to carry out all the works agreed upon, as well as to attempt to cure leaf-disease. The estate had not up to this time been drained, for the reason that we had two very dry seasons, and the soil being very friable it had not suffered in consequence; but I was about to drain the whole of it when the Government took over charge.

I may state here that in November 1879 I obtained a valuation of my estate from Mr. Stephens, in which he values the two year old coffee at £65 an acre, the year and a half old at £40, and the year old at £25 an acre, or the 355 acres at £11,700. He specially mentions the attack of leaf-disease, but says he shall adopt the best remedies known to eradicate it, and adds:—"The remedies that are to be applied, viz., *liming and sulphuring*, will greatly benefit the estate."

Under the Ordinance which was passed on the 22nd August 1879, Dr. McGregor was appointed Chief Commissioner and Director of Ceremonies, and no one can accuse him of not putting plenty of energy into his work. He determined, in order, I presume, to assist the operation of *stamping out*, to destroy all the coffee on the Rewa river on which the disease could be seen; but during this process, and notwithstanding all precautions, I believe, he carried the disease with him to those places which before were free from it. He burnt off, or caused to be burnt off, a number of most valuable nurseries, one containing upwards of 500,000 strong healthy plants, a patch of about 14 acres of magnificent two year old coffee, and Mr. Storck's plantation of about 30 acres.* No compensation has yet been paid by the Government for any of the loss thus occasioned, and none would be asked for, if it was thought the work had been honestly done for the benefit of the colony; * * * The natives' nurseries, which were full of disease, were situate within a short distance of some of the above, but they were not destroyed, for the simple reason that the *Govern ment were positively afraid to burn them!!* "What is sauce for the goose is" not "sauce for the gander" in Fiji; yet I know of a small plantation belonging to a European which was not even visited by Dr. McGregor or any of his assistants, and it was diseased.

On the 11th December 1879 a hurricane visited Fiji; the strength of the blow registered by my anemometer was 56½ miles an hour, although some of the puffs were doubtless stronger. At this time not a tree had been staked, as there was no labour to do the work; yet although the end of January was the time by which the whole of the staking was to be finished, if it had been commenced as soon as the estate was handed over, some 192 acres should have been completed by the 11th December, and the balance of the coffee being small, and a great deal of it unsupplied, the remainder would not have been affected in so serious a degree. To this hurricane I attribute in the first instance the ruin of my estate; but the subsequent action of the Government, or really of Dr McGregor, as Mr. Stephens was entirely under his control, will account for a great deal of the damage. After the blow the trees were put upright and earth trodden around them, but a very hot sun had scorched the roots before they could be replaced; and, as nearly all the taproots were twisted and broken, and the fibrous roots torn off, the estate never recovered the shaking it then got.

No cure for leaf-disease was attempted until the Government had the estate in their hands for six or eight months, for, although any number of native labourers were at their disposal if they had required them, they professed to be unable to get the lime burnt although coral reefs were situate within a few miles of the plantation. This dilatoriness on the part of the Government is merely another instance of breaking their agreement, by which they agreed to endeavour to *stamp out* the disease.

It must not be supposed that I was a passive spectator of all this inactivity. I was continually writing and urging the Government to act up to the agreement, to stake, drain, supply, &c., and particularly did I in December point out that 50 men were totally incapable of carrying out the whole works of the estate, and I said 150 were the *least* number that could do so; and I several times gave them notice that I should insist upon certain matters forming subjects of arbitration. No supplies were put in; no drains were cut until just before the Government relinquished charge, and then only done in a most perfunctory manner; no stakes were put in until February, and then only on the hilly and exposed places; and a troublesome weed was allowed to get a firm hold. All this time the estate was kept in strict quarantine, although the disease was nearly all over the group; but I shall never believe, through reading Mr. Stephens's letters, that quarantine was so strictly enforced for any other reason than to prevent the public knowing what experiments were being tried, and observing how Dr. McGregor by his treatment was ruining the estate.

Dr. McGregor and Mr. Stephens, assisted by one or two other embryo botanists, previous to May 1880, had tried many dozens of experiments; and Morris's lime-and-sulphur remedy having at that time proved a failure in Ceylon, they doubtless felt they were justified in experimenting on their own account. After all their trials there was but one which they thought could prove effective, and that was carried out as follows:—A coolie went up a row carrying a bucketful of boiled arrowroot, lime and sulphur, with which he painted every part of the stem and wood of the tree. Another followed with a basin containing hyposulphate of soda and water into which he dipped every leaf and branch, and a third with caustic lime dusted over the tree and ground. Although the cost of an experiment of this kind would have been enormous, cost was not taken into consideration. Some two or three weeks after Mr. Stephens had commenced this experiment, Mr. Storck paid him a visit to attend to my imported plants; and, being invited by Mr. Stephens to inspect the operations, Mr Storck shewed him the disease reappearing through the starch like paint, and in fact overtaking the operators.

Mr Stephens then told Mr. Storck that he was certain it was useless to continue the experiments, and he wrote to Dr. McGregor the same day and told him so. Although at this time but a comparatively small expense had been incurred in chemicals and materials, Dr. McGregor told Mr. Stephens to continue the

* This must have been before Mr. Storck had thought of carbolic acid fumes as a remedy for *hemileia vastatrix*.—ED.

operations, which he did, until the whole of the sulphur, &c., imported into the colony was used; and, a few days before the Government's occupation expired, 40 casks of sulphur were sent up to the plantation, and, as there was no lime left to mix with them, they were simply mixed with water and scattered broadcast over the estate. I believe a more wicked waste of Government money has never occurred in any colony.

In order the more effectually to cope with the disease—as Dr. McGregor said—he deemed it necessary to draw all the smaller timber into the ravines and burn it there; though why the larger trees were left is not very clear. Mr. Stephens wrote me on the 6th March 1880 to say that a very large quantity of the finest manure I could have for coffee, viz., the ash, would be lost unless I sent men to collect it, and that it would be a thousand pities if it were wasted. He said he had no houses to put any men in that I sent, although he said they would be put in quarantine; and, as I could not spare a hand from my adjoining sugar plantation, he, although the Government could have obtained a thousand men merely for asking for them, burnt the timber and neglected to apply or store the ash. The immense increase of surface wash which this suicidal act, before any drains were cut, has caused would alone have irretrievably damaged the property, as a large amount of the original surface soil has been swept by rain into the ravines.

The reports which I obtained about my plantation in October 1880 from practical men were that it could not be further profitably cultivated, as, since its management was undertaken by the Government, the coffee had suffered so lamentably that it was then without any value as a coffee plantation; and as soon as the twelve months had expired I tried my utmost to induce the Government to go to arbitration according to agreement, but I was unable to succeed. The Colonial Secretary (Mr. Thurston) would only consent to a gentleman acting as arbitrator for the Government of whose opinions he was well acquainted beforehand. He first proposed one and then another who had reported on my estate for the Government, evidently not wishing to remember that an arbitrator must come into a case with a thoroughly unbiassed mind. Eventually Mr. J. R. Hedges (a late member of your firm of Lee, Hedges & Co.) was agreed to by both sides, but he left the country very abruptly without acting. A Mr. Mason, whose limited coffee experience was obtained in Fiji, was next proposed, and all but agreed to by me; but I luckily discovered that he had reported against my estate and that Mr. Thurston had seen a copy of his report. You see how careful one has to be in order not to be caught by the trickery that is practised by Government officials in Fiji, although I told His Excellency in January 1881 that, if the Government would admit their liability to pay me compensation for my estate, I would wait until a loan was raised, so as not to hamper this impoverished colony, or I would have taken my claim out in land; but I received a reply from Mr. Thurston that "it was doubtful whether I was not indebted to the Government over the business, and not the Government indebted to me." With such an astute diplomatist working against me, what can I do? After Mr. Mason had been rejected Mr. Thurston said there was no one in the colony capable of acting as arbitrator for the Government, and that I must wait until Mr. Hedges returned. As there was no help for it I did so, but, as Mr Hedges was a friend of Mr. Thurston's, I regarded this dictum with a good deal of suspicion; and, when he came about three months later, he, after an interview with Mr. Thurston, insisted on an umpire being appointed from Ceylon. I ought to mention that there was no objection raised by the Government to my arbitrator, who was not a friend of mine, but I asked him to act because I believed he would give a conscientious award. So in July last year, nine months after the estate was abandoned, rather than be delayed any longer to please Mr. Hedges, I relaxed my efforts to get to arbitration, and issued a writ in the Supreme Court, which, as it turns out, was the worst step I could have taken. I now bitterly regret that I did not allow the umpire to be appointed from Ceylon, but, after waiting so long for the money which I felt I was justly entitled to, my patience was exhausted.

At our quarterly Supreme Court sittings in October I was quite prepared for trial. My witnesses were summoned from different parts of the group at great trouble and expense, and I hoped at last there would be an end of my troubles; but on the last day of the sittings the judge assumed that we were not ready, and, contrary to my urgent request to my counsel, as the judge wanted to remove to Suva on the next day with his wife and family, he adjourned the case until the following sittings in January. The case was then heard, and, if I had had a jury, my application for one having been refused, my counsel put such a strong case before the Court that I should have been certain of getting £20,000 damages. The judge, however, insisted upon trying the case himself, and, although he admits he is perfectly ignorant of coffee-planting, of chemistry, of practical agriculture, and the value of soils, yet he was not afraid to accept the responsibility of preventing a jury from giving just damages against the Government, and deciding on questions of fact himself. All my witnesses were gentlemen who saw the estate before the Government took charge, but I believe not one of the Government witnesses saw it until many months after the date of the hurricane. I have all along insisted that a view of the plantation was necessary before a just decision could be arrived at respecting it, and the judge a few weeks before he gave his judgment expressed his intention of going to inspect it; but he did not do so. His decision was not given until the 15th of last month (3 months after the evidence was taken), and, as an instance of his unpractical knowledge, he allows me £2,000 *for want of staking* (!); £1,000 for want of draining, £425 for not supplying, and £250 for crop of coffee; but he says I must pay one half the expenses, notwithstanding that, when I agreed to do this, I only thought, and so did Mr. Stephens, that Morris's lime-and-sulphur treatment would be tried—which amounts to about £1,600, and only leaves me upwards of £2,000 clear. He therefore admits that I have proved my most material claims for damages, but gives an amount totally inadequate to recoup my loss. If the Government had burnt off my plantation and paid me the £6 an acre compensation, as provided by the Ordinance of August 1879, I should, taking interest on borrowed money at 10 per cent into account, be nearly £1,000 richer now than this verdict will leave me!!! I produced accounts shewing that I was £10,000 at least out of pocket, and deducting the £2,000 I am therefore a loser of £8,000, besides wasting 5 years of my life. This is my only reward for acting in a patriotic manner and handing my estate over to the Government, so that the whole colony might benefit by the experiment to be carried out upon it.

Having issued my writ, my solicitor wished to retain counsel, and the following fact will shew you how I was prevented from obtaining fair play, and what notion Mr. J. H. Garrick, formerly Attorney-General for the colony, entertained of professional etiquette. Before the Government relinquished charge of my plantation a case was submitted to Mr Garrick for his opinion on the wording of the agreement and other matters (for which he charged more than 7 guineas),

and naturally therefore my solicitor offered him the retainer, as he had possessed himself of the chief points of my case, but, as Mr. Garrick refused to accept it, he retained another gentleman. Some months afterwards, when Mr. Garrick found he was not going to be retained by the Crown, he called and offered his services to my solicitor, who declined to avail himself of them. Mr. Garrick then went to the Attorney-General and offered them to him, I have no doubt at a very low rate, because he said in open court that he did not wish to be left out in the cold; the Attorney-General however was not instructed to retain him. He subsequently obtained a brief, I believe, at the special instance of Dr. McGregor, the fee on which was *only* £25; and Dr. McGregor stated, during the progress of the case, which lasted 3 or 4 days, that, unless he worked harder at it, he would not pay him at all. The Chief Justice allowed Mr. Garrick to appear for the Crown, notwithstanding my protest that he was well aware through reading my papers what the nature of my claim would be. Such, however, is professional etiquette at the bar of Fiji.

Mr. J. R. Hedges was called as a witness for the Crown, but unfortunately his evidence was taken on Commission, and therefore he was not put into the witness-box. He would have us believe that none in Ceylon knew anything about coffee planting there besides himself* although he admitted in cross-examination that he jumped at once into his magnificent position—as owner of thousands of acres of coffee property (2,919) and manager of tens of thousands of acres (13,342)—after two years' apprenticeship to Mr. Lee. From Mr. Hedges' own account, although not a chemist, he is a very good judge of soil—no one better. It was by *accident* he selected the land for a coffee estate in Morawak Korale, which afterwards died out on account of the land being thoroughly unsuited for coffee; it was not an error of judgment, and because he knew nothing about soil. He never visited my plantation until months after the Government handed it back to me completely ruined, and then from his previous vast and chequered experience he was able to say at a glance, and with merely a cursory examination, that the place was unsuitable for coffee-growing. In his opinion the hurricane which passed over the estate before the coffee was staked has *not* done it great damage; it is quite a mistake to suppose that hurricanes damage unstaked coffee irretrievably: he never heard of planting seed at stake, and does not believe that trees so planted give stronger and firmer roots than those from a nursery or stumps: in his opinion taproots would rot within 2 or 3 inches of the surface on sloping ground from excessive moisture, and draining would not prevent it: although he admitted finding almost any number of taproots where they had penetrated below the bottom of the original hole, this did not alter his opinion, &c, &c. A report which he had drawn up and signed that morning was handed in as evidence, notwithstanding a protest from my counsel against it being received. If Mr. Hedges had acted as an arbitrator he clearly shewed how thoroughly his mind was made up about the matter, and that he was quite prepared to ignore the chief duty of an arbitrator (an unbiassed mind) and to give me no damages.

Dr. McGregor said in the witness-box that Sir Joseph Hooker approved of all he had done. The letter from Kew which was produced in evidence was dated 8th June 1880, and no mention is made in that of *hyposulphate of soda*, which was Dr. McGregor's specific. This letter would reach the colony just before the estate was relinquished by the the Government, and after Dr. McGregor's experiments had proved abortive; but it is very significant, after what Dr. McGregor had said, Sir Joseph Hooker is silent on the point, and does not even *name* the chemical. Moreover Dr. McGregor must have written his letter, to which the one in June was a reply, sometime in March, before even he had decided on any special form of experiment. But he will no doubt claim that his name shall rank now with those of Abbay, Morris, Thwaites, Trimen, Ward, and Schrottky, but with this difference: where they have spent *hundreds* he has spent *thousands of pounds*.

To sum up what I have written above:—The disease was first noticed in May 1879.* The ordinance dealing with it was passed in August. The estate was handed over to Government in October; but they did not *commence* to attempt to cure the disease until March 1880! And yet they agreed to endeavour *to stamp it out!* Nearly all the time my estate was in the hands of the Government it was kept in strict quarantine, and no one was allowed on to it without having his clothes boiled, and his hat dusted with sulphur before leaving again, when the disease was at the same time all over the group. If I accept the £2,000 I shall be more than £8,000 out of pocket, with a valuless estate on my hands, and having lost five years of my life.

It was suggested to me several times that the reason Sir A. Gordon wanted to get my estate into the hands of the Government was because I had always been politically opposed to him, and fought most strenuously, though honestly, against his native policy; and that, if they ruined it, I should be ruined, and incapable of offering further opposition. This suggestion was always scouted by me until, under the direction of Sir A. Gordon's officials, and with the knowledge and consent of Sir A. Gordon himself (as his then Attorney-General, Mr. Garrick, has several times publicly stated), I was made to travel to the district in which my plantation is situated, and there to *stand* (a seat being denied to me) for two whole days in a felon's dock to answer a charge of "feloniously killing and slaying one of my labourers," but as soon as the evidence for the Crown was closed the case was dismised without my being called upon for a defence. A Governor who can descend to acts such as these makes it not impossible that the above suggestion may have been an honest one.

I have trespassed, I fear, too much on your favour, but, if any of your readers would furnish me with their opinions on my case, I should be extremely obliged to them. I have obtained leave to appeal to the Privy Council, but I question if it is a matter they could deal with.—Your obedient servant,

WM. FILLINGHAM PARR.

* Mr. Hedges is not the man to underestimate himself, quite surely he did not actually say this?—ED.

* Just ten years after it was observed in Ceylon.—ED.

MR. STORCK ON THE COFFEE-LEAF FUNGUS AND HIS PROPOSED VISIT TO CEYLON.

Belmont Plantation, Upper Rewa. May 23rd, 1882.

DEAR SIR,—*Hemileia vastatrix* dies hard, but whether the principle of apogestation have any existence in reality or no makes no difference in the value of my treatment. Break the chain anywhere and if *Hemileia vastatrix* had as many lives as the mythical hydra, it must die.

What, for instance, became of the permanent parasitical mycelium in the trees I have cured, and which are now standing for 21 months without any indication of a return of the disease?

More scientists appear in support of Mr. M. Ward's statement that the mycelium of a fungus is unassailable when once "safely ensconced" in the tissue of

a leaf, and which assertion I claim to have disproved. It is certainly far more intelligible to expect that, where the tube of a germinating spore, a comparatively solid body, can enter a stoma an atmosphere can follow, than to suspect a process of gestation in the very tissue of live plants, their seeds and juices.

Many thanks for the paper containing Mr. Sabonadiere's letter. The action that gentleman recommends, although not an absolute condition of success with my treatment, would be found to make a vast difference in the point of expenditure, and this is what I meant in my letter when I said that I "ventured to predict that when my treatment had been in general use for a twelvemonth in a district, the treatment could then be periodically discontinued," etc., etc. Mr. Sabonadiere hints at a total stamping out of the disease, which, in the abstract, is possible. I know nothing about your grubs in Ceylon, but as to the predilections of the genus generally, in tropical countries or elsewhere, I adhere to my original opinions.

I shall endeavour to be in Ceylon in October next to demonstrate my treatment and claim the reward, and in the meantime leave my interests in the keeping of the planters and the press.—Yours truly,

JACOB P. STORCK.

P. S.—For the *system of permanent vaporization through carbolic acid* I hereby *claim before yourself and the world priority of invention*, which priority I am in a position to *prove* step by step through my plantation *diary and my correspondence*. J. P. S.

THE CINCHONA GENUS AND THE SPECIES COMPOSING IT: CROSSES AND HYBRIDS.

DEAR SIR,—With regard to the interesting article in your paper of the 13th instant, I should like to make a few remarks. As to the origin of the cinchona genus, we may presume that all the numerous species which compose it can trace their origin back to one parent form, the progeny of which, extending over a large tract of country of varying conditions of soil and climate, have assumed permanently the form of growth best suited to these conditions; the fittest have survived in each case, and the characteristics which rendered them so have become permanent. These are the various *species* which compose the genus cinchona and, hybridization apart, the seed of any of them will produce plants referable to the same *species*, though they may shew numerous varieties. The indigenous and China Assam tea plants are, in the opinion of many authorities, true *species*. Though no doubt originally tracing their origin to one parent form, their characteristics are permanent, and, such being the case, they appear entitled to be considered separate and distinct species. The evidence that *C. robusta* is a hybrid appears very conclusive, and such is now the opinion of most authorities. That it is a hybrid between the two permanent species, succirubra and officinalis, is almost as clear. It is certainly not a variety of officinalis, as it is frequently raised from seed of succirubra trees. Now, individuals are classed under the same species—are varieties of it in fact—*when the difference between them is no greater than experience has shewn between plants raised from the same parent*. Thus from the seed of an officinalis tree of any type we may get specimens of the *varieties*, uritusinga, crispa, etc.; we should not get a succirubra plant; from the seed of an indigenous Assam tea tree, we should not get a China plant. The limits within which it is possible in the progeny of a plant to vary, coincide with the limits which include the members of the species of which it is representative. Unless, therefore, we change our definition of a species, we are bound to consider the various types of cinchona, succirubra, officinalis, calisaya, &c., with the indigenous and China species of tea, as having claims to specific rank.

An interesting paper has been published by Dr. Trimen in the *Journal of Botany*, entitled "Cinchona Ledgeriana a Distinct Species," in which it is stated that Mr. Moens has never seen "anything like Ledgeriana, either botanically or chemically," come from seed of a Calisaya.—Yours faithfully,

T. C. OWEN.

ARABIAN COFFEE IN CEYLON—IN DEFENCE: AND HOW TO CULTIVATE HIGH AND LOW ESTATES IN THE PRESENT DAY.

Maria Estate, 20th June 1882.

DEAR SIR,—I have been waiting to see some one take "Aberdonensis" to task for the manner in which he writes of Arabian coffee, but not finding any reply to date I cannot let his letter remain unanswered any longer. I had intended, however, not to write any more about Arabian coffee, but to work on with manures and disinfectants, and let those that are doubtful leave it alone, or come and see that it can be made to pay, if properly treated.

1. The letter of "Aberdonensis" speaks of the abundance of wood and the absence of crop. There are about as many high estates, which, as a rule, show abundance of wood and no crop, except in a very dry season. Here then is what I would say in such cases: Prune your trees of all superfluous wood in November, or December at latest. When dry weather sets in lay the roots bare, and put some country lime over the roots. If there is still too much sap, scrape with the back of the pruning knife the outside bark down to the white cambium in one or two places from top to bottom of tree, and you will let the superfluous sap escape, and secure a blossom which will give fruit and not turn into wood. The lime will keep leaf-disease away and summer the roots. Use disinfectants with manure (lime and ashes). Great mistakes are made in pruning for the sake of appearance and too much wood is left on the trees.

2. For low estates (especially on steep land) trench or waterhole, to save as much rainwater on your land as possible and let it soak into the ground. Apply your manure in holes; once in three years fork the ground; grow shade trees, but these trees must be thinned out or pruned when you find you have plenty of new wood on your coffee. If the roots of the shade trees damage your coffee, cut all the roots off that you find in one foot depth all round the tree. Do not cut all branches off and merely leave a crown at the top, but cut all branches off up to 10 feet from the ground. Then select so many (say eight) primaries, good distances apart, cut all others off and top your trees at 20 or 25 feet. The deep roots of the shade trees will be able to feed on nourishment which has gone below the coffee trees, and the leaves will absorb nitrogen from the atmosphere. Jak, suriya and croton are some of the best trees for shade. By all means plant all new products among coffee. As regards comparing Arabian coffee with Liberian, I can show Arabian coffee four years old beating Liberian of the same age by one-third of crop, both close together; and I have some old Arabian which no Liberian can beat. I have both growing. Learn to know the wants of Arabian coffee trees from the looks of the tree (leaves and new wood); attend to its wants, and it will pay better than Liberian coffee, at least at 1,800 feet elevation.—Yours truly, J. HOLLOWAY.

P.S.—With reference to your correspondents, "Tell the Truth," "Kelebokka," and "E. C. B." I must refer them to my previous letter, and my challenge last year, and I can at all times prove statements made by me. As regards the poetry of "E. C. B." dedicated to James Holloway (I presume he meant me), I can only say if I could not rhyme better I would not send that epistle to the papers. J. H.

CINCHONAS ON FLAT LAND.

DEAR SIR,—Can you inform me whether cinchonas will, or will not, grow on flattish land? A planter told me the other day I was simply wasting valuable plants in planting them in some 15 acres of flat land—very little slope—that I want to put into cinchona succirubra.—Yours truly, CINCHONA.

[Dr. King lays it down in his manual that cinchonas absolutely refuse to grow on flat land, and that is generally our experience. We saw a marked exception in Java, however, a grove of magnificent succirubras, near Junghuhn's grave, growing on perfect flat. But the soil was deep, free volcanic matter, though moisture easily percolated. The question, therefore, here, will be one of a subsoil so constituted as to allow of perfect natural drainage. If the subsoil is clayey and stiff, we fear disappointment will follow planting.—ED.]

CINCHONA BARK: LOCAL MARKETS AND ANALYSES.

21st June 1882.

DEAR SIR,—I quite agree with what "Live and Let Live" says in his two letters.

I am convinced there is no market at all in Ceylon for cinchona bark, in spite of the brokers, analyzers and German firms pretending there is an uncommonly good one.

I certainly would advise all cinchona growers to send their bark home, where they would get some profit.

On perusal of your paper of the 19th inst., I see that Messrs. Lewis & Peat's sale account of May 25th states that Ceylon red twigs and young branch sold at 6d to 1s 6d per lb., whereas locally we only get 19c per lb. for this.

Of course, I make allowance for the brokers, as they must live by selling something, now that there is no coffee; but, in these hard times I don't think it is right for them to take advantage of the unfortunate producers.

Each unit of quinidine is worth 66c per lb.
Cinchonidine ... ... 25c ,, ,,
Cinchonine ... ... 11c ,, ,,

and the usual analysis of Ceylon red bark irrespective of quinine is:—

1	per cent of	quinidine	value 66c	per lb.
2	,,	,, cinchonidine	,, 50c	,, ,,
1·75	,,	,, cinchonine	,, 18c	,, ,,
4·75	...	...	...	Total...R1·34 per lb.

Trusting that Ceylon brokers will take notice of the few remarks made here by A LATE BROKER.

VARIEGATED CINCHONA LEAVES.

Dikoya, 22nd June.

DEAR SIR,—I enclose you a leaf from a cinchona succirubra plant about 18 months old. All the leaves on the plant are variegated in a similar manner. Is n't this a phenomenon?—Yours faithfully, A. W. B.

[Arabian coffee, which belongs to the *cinchonaceæ*, sports occasionally into very beautiful yellow leaves, while we have seen tea leaves white as snow. Variegated foliage on the true cinchonas seems a rare "phenomenon" The leaf sent to us has put on yellow near the point and the appearance is a good deal that of variegated coffee.—ED.]

CINCHONA SUCCIRUBRAS FLOURISHING ON FLAT LAND.

Radella, Liudula, 22nd June 1882.

SIR,—In your issue of the 20th, I notice "Cinchona" 's query as to whether cinchona will grow on flat land, and your editorial note in which you quote Dr. King to the effect that cinchonas absolutely refuse to do so; in which assertion, I beg to join issue with Dr. King, in proof of which I will gladly show any one some of the finest succirubra trees of their age (4 to 5 years) that you can find in this neighburhood growing on absolutely flat land, as flat as the Radella cricket ground and separated from it only by the river.—Yours, &c. WM. MITCHELL.

COVERING CINCHONA TREES.

No. I.

DEAR SIR,—I shall feel much obliged if you, or some of your numerous readers, would enlighten me on the subject of covering cinchona trees after shaving. I have heard that blue gum leaves have the effect of poisoning the bark, also that guinea grass causes canker. Again it has been suggested that the leaves of cinchona and most jungle trees would be injurious to the bark. As we all know, most leaves turn into pulp so quickly and thereby contract too much moisture. What effect then I should like to learn would Mauritius, mana grass, or any other vegetable covering have?—Yours faithfully,

DIKOYA PLANTER.

No. II.

Maskeliya, 26th June, 1882.

DEAR SIR,—Will you, or any of your numerous correspondents, kindly give your experience of covering shaved cinchona trees with guinea grass. I have been told by a neighbour that guinea grass, leaves, and jungle stuff are unsuitable for covering, as it causes the bark to canker. Is such the case?

SUCCIRUBRA.

[We advise our correspondents to experiment themselves with the various substances they mention and watch the result. Hitherto, the experience has been very varied in different districts: we have seen grass answering the purpose well in one case, and in another proving a cover for myriads of insect which appeared to injure the bark. Cinchona leaves do not seem to be a favorite with insects, but they are not so lasting as grass. At a high elevation, trees have been known to put on bark as quickly without, as with a covering; but the general belief (and analyses seem to bear it out) is that the uncovered renewed bark is not equal in quality to that protected from the sun. A great deal has yet to be learned as to the best and cheapest covering for shaved cinchona trees.—ED.]

CINCHONA BARK: THE LOCAL *VS.* HOME MARKET AND ANALYSES.

Colombo, Ceylon, 28th June 1882.

SIR,—It is to be regretted that your jocular correspondent, "A Late Broker," did not make it clearer in his letter of the 21st inst., that he only intended to joke fun at "Live and Let Live," and it may be useful for all concerned to have "A Late Broker" 's figures worked out a little further.

As quinine has about double the value of quinidine, I may, taking "A Late Broker" 's figures as a basis, say that a unit of quinine is worth R1·20. Bark, according to the "usual analysis" of Ceylon red bark, has therefore a value of:—

1 p.c. quinine .. 1·20
1 p.c quinidine... ·66
2 p.c. cinchonidine ·50
1·75 p.c. cinchonine ·18

Total	...R2·54	per lb of bark	with	1	p.c.	quinine		
or	,, 3·74	,,	,,	,,	,,	2	,,	,,
or	,, 4·34	,,	,,	,,	,,	2½	,,	,,

To net those prices, taking drying loss and packing charges into account, amounts of respectively about 5s 6d, 8s and 9s 4d per lb. in London public sale would be required. As, however, Messrs. James Cook & Co., in their circular of the 25th May, quote Ceylon red bark :—

Fair to good quill	... ...	2s to 3s,
Young branch	.. ..	1s ,, 1s 6d,
Chips	... ...	1s ,, 2s,
Shavings	... ...	2s ,, 3s,
Twigs	... ...	4d ,, 8d,

I am afraid anybody who was to buy in Colombo at "A Late Broker"'s figures would let live, certainly, but not live himself very long.

Quinine manufacturers are not so dense as not to find out the market in which it is cheaper to buy ; most of them have tried Colombo, and (with one exception, which might be explained) have declared that, as long as present prices are kept up in Colombo, they *can buy cheaper in London*, and as moreover they back their opinion by acting upon it, it may safely be inferred that local buyers on the average have offered and paid as good prices as planters could expect to get anywhere. Against individual cases in which bark at home fetched more than was offered here, I am prepared to quote others, which ended in a total loss to the local buyer.

Differences of analyses turn up everywhere, and local analyses have stood the test of manufacturers as well as those made by professionals in London.—Yours faithfully, MERCHANT.

SUGAR-GROWING IN THE NORTHERN TERRITORY.—The following is a copy of a telegram from the Government Resident, Northern Territory, to the Hon. the Minister of Education, dated May 31st.—"Owston arrived from Daly River yesterday, bringing splendid sample of cane grown on Palmerston Plantation Company's estate. All his cane in first-class condition, and quite equal to cane in Nursery."—*Adelaide Register.*

FORESTS.—The Secretary of State for India has selected Mr. Edward Dobbs, L.L.D., First Assistant Conservator of Forests under the Government of India, now on furlough, for the post of Conservator of Forests in Cyprus as a temporary arrangement. Mr. Dobbs while so employed will receive a salary of £400 per annum, with an extra house allowance of £50, and all his travelling expenses will be paid —*Pioneer.*

ANALYSES OF BARK.—Prollius's methods for the estimation of the total alkaloid in bark have been tested by Dr. J. Biel (*Pharm. Zeitschr. f. Russland*, xiii., 249), who worked independently of Dr. de Vrij (see *Pharm. Journ.*, [3], xii., 765), but arrived at similar results. Like Dr. de Vrij, Dr. Biel rejects the extraction with chloroform mixture as inaccurate, and recommends a modification of the ether-ammonia process, in which the powdered bark (either South American or East Indian) is macerated for four hours with ten times its weight of ethereal mixture, filtered, decolourized if necessary with powdered lime, and a weighed portion of the filtrate evaporated to dryness. The crude alkaloid thus obtained is dissolved in dilute acid and extracted by shaking with chloroform after the addition of ammonia. The alkaloid left on evaporating the chloroformic solution is dried and weighed and may be purified, if great accuracy is desirable, by dissolving in acetic acid and weighing the residual resin. The most important difference between Dr Biel's and Dr. de Vrij's modifications seems to be in the length of time required for the complete extraction of the alkaloid from the bark, the latter being of opinion that one hour is sufficient, whereas the former maintains that the results will be inaccurate, if the stated period of four hours is not strictly adhered to.—*Pharmaceutical Journal.*

SHEVAROY, June 16th.—The season has turned out, much to our delight and satisfaction favourable and full of promise for the future. Blossom has set very fairly owing to timely and copious rains in April, which have continued almost without intermission up to the present moment. Should nothing now intervene in the shape of the hundred and one "ills" to which coffee is "heir," there is no reason why the long-expected bumper should not be realized. Such a result after two bad seasons would be highly satisfactory, and the anticipation alone is sufficient to put us in good spirits. An auction sale of land under the Waste Land rules took place on the 15th ultimo, when several lots were knocked down at very little over upset prices. The average rates obtained on this occasion were about R3½ per acre—a perfect contrast to a former sale, when, competition being brisk, R30 and 40 was obtained.—*Madras Times.*

THE WASTE LANDS IN THE TAVOY DISTRICT.—A correspondent sends us the following extract from a private letter in reference to the forest in Burma now being advertized :—"I enclose you an advertizement of our Government which may interest you. It is the outcome of a planter—late of your island—who has taken grounds at Johore and who was up here on a visit about a couple of months ago. He visited the district now advertized, and thought so much of the suitability of the place for coffee that, had he seen it before he went to Johore, he would never have gone there. I understand that he has had some ground allotted to him. I fancy the district advertized is a perfect jungle inhabited by tigers and other wild beasts. Some eight or ten years ago, Mr. ——— started a tin mine in that quarter and he had to import all the labour—Chinese. The adventure resulted in the loss of about £20,000, and now the place is abandoned. One of the men who were down there told me that a tiger jumped in at the cookhouse window, and carried off what he could get hold of."

COCHINEAL CULTIVATION IN TENERIFFE.—In consequence of the extended use of aniline dyes, the cultivation of cochineal in Teneriffe has received a severe check, so much so that a great many growers are reported to be utterly ruined. The result of this, we read in a recent report, has been that considerable attention has been directed to the cultivation of tobacco. At first this new production gave promise of a favourable result, there being a fair quantity collected, and the quality approaching to that of the Cuban tobacco. In consequence of the Spanish Government not fulfilling their promise to purchase the tobacco crops for a period of three years, the growers found themselves with their warehouses filled without any prospect of a speedy or remunerative sale. This induced them to abandon tobacco cultivation, and to return to that of cochineal ; but, owing to a great fall in prices—below, indeed that limit at which growers find their crops pay—they have since attempted sugarcane, the proprietors of the plantations having sent a deputation to the island of Madeira to study the making of sugar, treacle, and rum. Although the majority of the growers think that the new production will give an impetus to agriculture, some of the principal persons in experience and knowledge doubt whether this cultivation will give good results, on account of the high price of land, while labour is dearer than in those countries where this article is usually produced. The cultivation of the almond is yearly falling off, on account of the indolence of the growers, who do not take the least care of the trees already planted, and never think of planting new ones. Within the last two years the cultivation of the banana has considerably increased, and may now be considered as an article of export which is gradually increasing.—*Gardeners' Chronicle.*

NEW PRODUCTS: CEYLON COCOA IN THE LONDON MARKET.—It is reported that a sale of Gangaroowa (? Gangwarily) cocoa in Mincing Lane at 120s per cwt. had created quite a sensation in "the City." There can be no doubt that our "new products" are attracting attention to and renewing confidence in the future of Ceylon at home. The success of shaving and coppicing cinchona has changed what was regarded as a very uncertain spasmodic type of enterprise, to one as regular and profitable in its returns as any connected with the tropics. A West Indian colonist now on a passing visit to Ceylon (*en route* round the world) has been astonished at the advanced and luxuriant growth of cocoa in Dumbara and North Matale: on one group of estates alone there are 1,200 acres of cocoa in the latter district, and a good deal amongst the coffee which does not seem to injure it in any way. All this is very satisfactory, but what is to be done in the meantime to secure financial aid: agents and banks seem to have come to a standstill as regards new business, and cash credits or mercantile advances seem unobtainable by "New Products" cultivators. WANTED: A "NEW PRODUCTS BANK"!

MR. STORCK AND HIS REMEDY FOR COFFEE LEAF DISEASE.—AN Australian correspondent writes:—"I enclose extract from the Melbourne *Leader*, which gives in a succinct form a statement of Mr. Storck's remedy:—

A cure for the coffee leaf-disease (*hemileia vastatrix*) has happily been discovered by a gentleman in Fiji—Mr. J. P. Storck, Belmont Estate, Rewa River, formerly assistant to Dr. Seeman, who, in a communication to the *Gardeners' Chronicle* of 18th February, gives the name of the substance and his manner of application. The principle of the method is the diffusion through the plantation of carbolic acid vapor injurious to the fungus. His plan of procedure is to place in the plantation a number of tin vessels, about 36 to the acre, with a cover over each to keep out rain and dirt. The fluid consists of a mixture of carbolic acid and water, in the proportion of 8 to 10 per cent of Calvert's best No. 5 acid, but a greater strength may be used, since the acid does not touch either the plants or the soil. After clearing his trees and enjoying an immunity from the disease for eleven months, a gang of laborers brought back the infection from another plantation and the treatment had to be recommenced, but the infected trees were speedily cleared. The vessels after being filled require to be replenished weekly with the acid so long as the disease remains. Mr. Storck applied to the Fijian Government for protection of his invention and was refused on the strength of the local Patent Ordinance, which only partly covers the subject of his discovery, and only applies to inventions of a purely mechanical nature, so that, in making known his discovery for the benefit of the countries and planters suffering from the ravages of the *hemileia*, he can only "rely, as regards his rights of priority and proprietorship, upon that spirit of justice and fair play so generally obtaining in the scientific and planting world.

"A relative in Fiji tells me that Mr. Storck is a German and a very clever scientific man; he mentioned his having on his own coffee plantation cured the disease, but at that time he said he would not make his secret known, as he expected he should get a reward from the Fijian Government for it: this the Government has been unable to grant him, and he has now disclosed it trusting, as he remarks, to the generosity of those who may benefit by using this cure. There seems to be no deception about the cure."

A Ceylon proprietor expresses his opinion on the above thus:—"I quite agree that for all experimental purposes 8 to 10 per cent of carbolic acid ought to be persisted in, and not once 10 per cent, and afterwards 5 per cent, as recommended by Mr. Storck in the *Gardeners' Chronicle*. If 10 per cent fails then of course it would be no use trying 5 per cent."

CEYLON TOBACCO.—In a recent issue we noticed the sale of 80 bales of Ceylon tobacco of promising quality, but badly packed, and consequently realizing a poor price. We are glad to learn that an experimental shipment of thirty tierces of Indian leaf, from a manufactory in Bengal, has turned out satisfactorily. It was pronounced by the experts, both merchants and brokers, to be of excellent quality, fully equal to American, and fold well.—*Planters' Gazette.*

THE INDIA-RUBBER plant is cultivated successfully by the Forest Administration department at Mergui, where there are also four vanilla plants and 24 rain-trees flourishing. Coffee and tea have been grown successfully at some of the plantations, the former doing better than tea. Cinchona thrives nowhere in Burmah, the heat being too great for it, and an offer of R100 reward to Karens to undertake its cultivation on the Tounghoo hills did not induce one single applicant for plants. The Forest Department have determined upon handling yearly some thousands of other trees than teak; so as to always have a supply of good seasoned timber on hand for the Public Works Department and for private consumption. By this means, it is hoped that the local expenditure of teak will be reduced, and that larger quantities will be set free for exportation to Europe and India.—*Friend of India Rangoon Correspondent*, May 29th.

LABOUR IN FIJI.—The fact that the advantages presented by the rich and fertile lands of this Colony are beginig to attract the attention of capitalists from without, is at once apparent from the fact that the proprietary of the Mago Island Company of Victoria have become the purchasers of the Islands of Kanacea and Cicia from the present owners at a very satisfactory price, while other men of capital who have recently immigrated hither are now extending their operations, as instance the purchase by Messrs. Harris and Akers, of a large and valuable block on the Dreketi River. There is no scarcity of good land, both in Viti Levu, Vanua Levu, Taviuni, and the various islands which make up the Windward group good land abounds, the only difficulty in selecting a suitable holding out of such an *embarras de riches*, and the only one thing necessary in order to make the cultivation of sugar cane or of any other tropical product remunerative being a regular and abundant supply of labor, and this it must be the constant aim not only of the Government, but of every one interested in the matter to obtain. It is a peculiarity of tropical produce generally that it requires a larger amount of manual labor than the products of more temperate climes. It therefore becomes a necessity to have abundance of cheap labor before the richness of the soil can be remuneratively availed of. It appears to us doubtful if the coolie labor which the Government seem so anxious to introduce will prove equal to the occasion at all, for there are many reasons why their influx here in large numbers would be objectionable, not the least of which is the growing jealousy and dislike with which they are regarded by the Fijians, which might lead to serious results, if any contagious disease was introduced by them. Under any circumstances the Polynesian is a far more useful immigrant, and we trust to see the efforts which are now being made to secure an increased supply of this description of labor from the Western Pacific, redoubled in order that the only existing drawback to the settlement and improvement of the waste lands of Fiji may be speedily removed.—*Fiji Argus.*

[The settlers in Fiji are the best judges of their own affairs, but as Fijian natives are not available as labourers, and as the supply from other islands of the Pacific is daily becoming more difficult to obtain, progress must come to a stand or be greatly hindered, unless cooly labour can be utilized.—ED.]

MEDICINAL PLANTS IN INDIA AND THE DISTILLATION OF ESSENTIAL OILS, PERFUMES, &c.—NEW INDUSTRIES FOR CEYLON.

Amongst the papers we have received from the Madras Government is copy of a letter from Surgeon-General Cornish, specially dealing with the growth in India of Hyoscyamus (*henbane*), but noticing besides other drugs the extract from leaves of the Australian blue-gum, which is a valuable antiseptic. Mr. Bosisto, M. P., Chemist, of Richmond, near Melbourne, had in the Exhibition of 1880-81 a very large collection of preparations from the *Eucalypti* and other trees of similar properties, and we should think that even with cost of carriage the extract could be more cheaply obtained from Melbourne than prepared in India. As the experiment is to be tried, however, we shall be curious to know if the trees naturalized in India and Ceylon are as rich in essential oil as they are in their native habitat. We quote as follows :—

"A packet of Hyoscyamus seed was received by me from the Collector of Nilgiris. I have to point out that seeds of this plant are not used in medicine. An extract is made from the fresh leaves, and a tincture from the dried leaves. Formerly, when a medical officer was stationed at the Cattle Farm, Hoonsoor, Hyoscyamus was cultivated there, and the requirements of the Medical Store Department in the way of extract, and dried leaves were met from this source, but some bad extract having been made, and the charges for cooly labour in cultivating and making the extract, costing more than the English price of the drug, the local cultivation and manufacture was abandoned and Hyoscyamus extract and leaves procured from England. Of late years, however, the medicinal garden at Ghaneshkhind, Bombay Presidency, has supplied the medical store requirements in the way of Hyoscyamus leaves and extract, and none has been procured from England. From the enclosed letter from the Principal Medical Storekeeper it will be observed that the Ghaneshkind samples of Hyoscyamus leaves and extract are of excellent quality The price of the leaves is 6 annas per lb., and of the extract R1-8-0 per lb., delivered in Madras, and these rates are considerably below the English prices of the articles. Unless, therefore, the Superintendent of the Government Gardens, Ootacamund, could supply the medical stores at lower rates than those quoted, there would be no advantage in obtaining the supply locally. I believe the Ghaneshkhind medicinal garden is aiming to supply all India with drugs that can be locally cultivated to advantage, and, as Hyoscyamus grows best in the medium climates of Hoonsoor and the Deccan, it is doubtful if it is worth while to grow it at Kulhutty, on the small scale necessary for meeting the requirements of the Madras Medical Store Department. The extract can be made cheaper when the manufacture is conducted on a larger scale. The climate of the Nilgiri Hills is well adapted for the growth of *jalap*, and the gardens should soon be able to supply all the medical stores in India with a sufficiency, even if the drug does not become a commercial export. The essential oil of peppermint, now imported at a high price, ought also to be produced at Kulhutty at a cheaper rate than it can be imported. I should wish also to have locally prepared the essential oil of the blue-gum (*Eucalyptus globulus*), which is now coming into use, (recommended by Professor Lister) as an antiseptic, and used instead of carbolic acid in spray, during surgical operations. I propose to have some experimental trials of the production of the essential oil from the leaves of the blue-gum."

In this connection we call attention to the letter of Messrs. Hutchison & Co., in another column. There can be no doubt that there is scope for an extension of the present low-country industry in the preparation and export of Essential Oils. The late Mr. George Winter of Baddegama was, we believe, the first to pay attention to the cultivation of citronella and lemongrass, and his descendants continue to manufacture a large proportion of the oil which now leaves the Colony, mainly to be used in scenting soaps, for perfumery, &c. On Lord Elphinstone's Pauadure property under the care of Mr. S. W. Foulkes, a large quantity has also been prepared for export and of recent years the cultivation of citronella (*Andropogon citratum*) and the distillation of the oil have been extending to various points along our Western seaborde. We learn from Mr. W. A. Lyford, who not long ago exchanged coffee planting in the Pundaluoya valley for a plantation in the Balapitimodara district, in which the cultivation of Liberian coffee and tea is conjoined with that of citronella, that the still for the last-mentioned (manufactured by the natives of copper sheets) is a very simple affair, and that there is no difficulty about the operation. But the sum (45s) mentioned by Messrs. Hutchison & Co., as the cost of a still adapted for the extraction of volatile oils is so moderate as to place it within easy reach of pioneers. We were struck the other day with the luxuriant growth and strong perfume of the geraniums almost running wild in bungalow gardens and along estate paths in Maskeliya and the thought at once suggested itself why not cultivate these and distil the essential oil. Patchouli would no doubt be as valuable a perfume as any to experiment with and the Indian herb (*Pogostemon patchouli*) from which it is obtained, would grow freely. Altogether our hill, as well as low, country presents a wide field for experiments of commercial value in this direction, and we shall be glad of the further information which Messrs. Hutchison & Co. promise to send. Not only the leaves of the Eucalypti so freely growing in our higher districts, but the indigenous mana-grass of our patanas may well be operated on.

The value of Essential Oils exported from Ceylon was £8,238 in 1850, rising to £13,141 in 1865, while in 1871 it had fallen to £11,098. Last year, however, the total value was close on £29,000, made up as follows :—

Citronella	Oil ...	(Customs' nominal value)	R247,413
Cinnamon	,, ...	,, ,,	31,067
Cinnamon Leaf	,, ...	,, ,,	5,018
Lemon Grass	,, ...	,, ,,	1,751
"Essential"	,, ..	,, ,,	4,190
		Total	R289,439

RIVALRY IN SILK AND TEA.

A Chinese tradition attributes the discovery of silk to one of the wives of the Emperor of China, Hoang-ti, who is said to have reigned about two thousand years before the Christian era; and since that time—so the tale runs—a special spot has been allotted in the gardens

of the Chinese royal palace to the cultivation of the mulberry tree—called in Chinese the 'golden tree'—and to the keeping of silkworms. Without waiting to discuss the probabilities of this item of folklore, which has possibly as much foundation in fact as most other popular notions on similar subjects, we proceed to known facts. The mulberry plant is a native of Persia, from which country the secret of silk manufacture was introduced into Italy *vid* Constantinople, and over Europe, becoming domiciled in the south of France as a great manufacturing industry before the close of the fifteenth century. This is a brief historical summary of an article now used in nearly all countries as a luxury in apparel, but only befitting those of a higher social gradation, or those whose means permit of the indulgence of wearing such a comparatively costly textile fabric. Sericulture is now extensively practised in various parts of the world, temperate and tropical. The conditions which favour the plant are prejudicial to the insect, and *vice versa*. The mulberry thrives better in a cold climate, which implies a larger size of tree bearing a more abundant crop of leaves than in warm regions. But in these latter the silkworm develops more rapidly and obtains maturity in less than half the period in the former or colder localities. This is an overwhelming advantage, as it minimizes attendance and risk by a saving of more than three weeks. Cards of seed carried from China and Japan have been found to reproduce successfully in those countries where the mulberry can be cultivated. The silkworm has been introduced into various parts of America with favourable results: but the most interesting sericultural experiments of the period are those now undertaken in reference to the acclimatization of the insect and plant in Australia and Ceylon, in both of which countries there are reasonable grounds for believing that silk-growing may in time prove a profitable industry. "In Europe the silkworm takes about forty-five days to obtain maturity, but it has been found by experience that in the temperature of Colombo only from twenty-three to twenty-five days are required." This quotation supports what we have already stated on this subject. It is a most important consideration, as the shorter period reduces the liability of loss from disease, and other well-known causes which prey upon the worm, as well as lessening the cost and trouble in looking after it. We have been induced to dwell upon this subject from the apparent fact that local products, which at one period were almost exclusively confined to China, have been produced successfully elsewhere, and, in some instances, left China far behind in the competition. This is particularly conspicuous in the matter of porcelain wares. The chief exports of China are, as our readers are doubtless aware, tea and silk. India is fast assuming a position in reference to China tea that, judging from the progress made during the past few decades, there is every possibility in the immediate future of its becoming something more than a powerful rival. In silk, China will have to dread a more widespread competition. It forbodes ill, as regards the future of this industry in China, that sericulture is commencing to be developed in intertropical countries, which will preclude China from monopolizing the advantage she possesses *re* cheapness of production. It has been already acknowledged that silk growing cannot be remuneratively carried on by white labour in Australia, which objection does not exist or militate against the industry in Southern Europe. The conditions are, of course, different in Ceylon, where coloured labour is the only agency that could be employed for the purpose, and it is chiefly from such countries that China and Japan have to dread rivalry. —*China Mail.*

ORIGIN AND PROGRESS OF TEA IN INDIA.

[Our own notes to this article taken from Dr. Hunter's "Indian Empire," will be recognized by the usual Ed. Those signed "Ed. *I. T. G.*" are by the Editor of the *Indian Tea Gazette*.—Ed.]

The cultivation of tea in India commenced within the memory of men still living, and the industry now surpasses even indigo as a field for European capital. Unlike coffee-planting, the enterprize owes its origin to the initiation of Government, and it has never attracted the attention of the natives. Early travellers reported that the tea-plant was indigenous to the southern valleys of the Himalayas; but they were mistaken in the identity of the shrub, which was the *Osyris nepalensis*. The real tea (*Thea viridis*), a plant akin to the camellia, grows wild in Assam, being commonly found throughout the hill tracts between the valleys of the Brahmaputra and the Barak. It there sometimes attains the dimensions of a large tree; and from this, as well as from other indications, it has been plausibly inferred that Assam is the real home of the plant, which was thence introduced at a prehistoric date into China. The discovery of the tea-plant growing wild in Assam is generally attributed to two brothers named Bruce, who brought back specimens of the plant and the seed, after the conquest of the Province from the Burmese in 1826. In January 1834, under the Governor-Generalship of Lord William Bentinck, a committee was appointed "for the purpose of submitting a plan for the introduction of tea-culture into India." In the following year, plants and seed were brought from China, and widely distributed throughout the country. Government itself undertook the formation of experimental plantations in Upper Assam, and in the sub-Himalayan districts of Kumaun and Garhwal in the North-Western Provinces. A party of skilled manufacturers was brought from China, and the leaf which they prepared was favourably reported upon in the London market. Forthwith private speculation took up the enterprize. The Assam Tea Company, still by far the largest, was formed in 1839, and received from the Government an extensive grant of land, with the nurseries which had been already laid out. In Kumaun, retired members of the civil and military services came forward with equal eagerness. Many fundamental mistakes as to site, soil and methods of manufacture were made in those early days, and bitter disappointment was the chief result. But while private enterprizes languished, Government steadily persevered. It retained a portion of its Assam gardens in its own hands until 1849, when the Assam Company began to emerge from their difficulties. Government also carried on the business in Kumaun under the able management of Dr. Jameson, as late as 1855 *

The real progress of tea-planting on a great scale in Assam dates from about 1851, and was greatly assisted by the promulgation of the Waste-Land Rules of 1854. By 1859, there were already 51 gardens in existence, owned by private individuals; and the enterprize had extended from its original headquarters in Lakhimpur and Sibsagar as far down the Brahmaputra as Kamrup. In 1856 the tea-plant was discovered wild in the district of Cachar in the Barak valley, and European capital was at once directed to that quarter. At about the same time tea-planting was introduced into the neighbourhood of the Himalayan sanitarium of Darjeeling, among the Sikhim Himalayas.†

* Entirely with the China variety or *species* (?).—Ed.

† Again the China tea was that used. All the older hill gardens were planted with the China bushes, and it is only within a comparatively recent period that Assam hybrid plants have been introduced. Most of the Terai estates have been planted with the superior tea.—Ed.

The success of these undertakings engendered a wild spirit of speculation in Tea Companies, both in India and at home, which reached its climax in 1865. The industry recovered but slowly from the effects of the disastrous crisis, and did not again reach a stable position until 1869. Since that date, it has rapidly but steadily progressed, and has been ever opening new fields of enterprize. At the head of the Bay of Bengal in Chittagong district, side by side with coffee on the Nilgiri hills, on the forest-clad slopes of Chutia Nagpur [anciently Chota Nagpore!—ED.], amid the low-lying jungle of the Chittan Dooars, and even in Arakan, the energetic pioneers of tea-planting have established their industry. Different degrees of success may have rewarded them, but in no case have they abandoned the struggle. The market for Indian tea is practically inexhaustible. There is no reason to suppose that all the suitable localities have yet been tried; and we may look forward to the day when India [and Ceylon.—ED.] shall not only rival, but supersede, China in her staple product.

The following statistics, unless otherwise stated, refer to the year 1877-78. The total area taken up for tea in Assam, including both the Brahmaputra and the Barak valleys, was 736,082 acres, of which 538,961 acres fit for cultivation; the total number of separate estates was 1,718; the total outturn was 23,352,298 lb. at the average rate of 286 lb. per acre under mature plant. In Bengal, the area taken up was 62,642 acres, of which 20,462 acres were under mature plant, including 18,120 acres in the single district of Darjeeling; the number of gardens was 221; the outturn was 5,768,654 lb. at the rate of 282 lb. per acre under mature plant. In the North-Western Provinces, there were, in 1876, 25 estates in the districts of Kumaun and Garhwal, with an outturn of 578,000 lb., of which 350,000 lb. were sold in India to Central Asian merchants; and in 1871, 19 estates in Dehra Dun, with 2,024 acres under tea, and an outturn of 297,828 lb. In the Punjab, there were 10,064 acres under tea, almost entirely confined to the Kangra district, with an outturn of 1,113,106 lb., or 111 lb. per acre. In Madras the area under tea on the Nilgiris was 3,160 acres; the exports from the Presidency were 183,178 lb., valued at £19,308. Excluding the figures just given for Madras, the whole of the Indian tea is shipped from the port of Calcutta, and almost the whole is sent to the United Kingdom. The total exports by sea for 1877-78 were 33,459,075 lb. valued at £3,044,571. Of the total supply, about 26,000,000 lb. came from Assam, about 8,000,000 lb. valued at 787,000 lb., from the North-Western Provinces, and 684,000 lb. from the Punjab. In the same year, the exports of tea from the Punjab to Central Asia were returned at 1,217,840 lb., valued at £181,634, being a considerable decrease on the previous year. In the year 1879-80, the exports of Indian tea to Great Britain rose to 40 million lb., and new markets have been successfully opened in Australia and the United States.

These processes of cultivation and manufacture are very similar throughout the whole of India, with the exception that in Upper India the leaf is prepared as green tea for the markets of Central Asia. Three main varieties* are recognized—Assam, China, and Hybrid. The first is the indigenous plant, sometimes attaining the dimensions of a tree, yielding a strong and high-priced tea, but difficult to rear. The China variety originally imported from that country, is a short bushy shrub, yielding a comparatively weak tea and a small outturn per acre.* The third variety is a true hybrid, formed by crossing the two other species. It combines the qualities of both in varying proportions, and is the kind most sought after by planters. In all cases, the plant is raised from seed, which in size and appearance resembles the hazel-nut. The seeds are sown in carefully prepared nurseries in December and January, and at first require to be kept shaded. About April, the seedlings are sufficiently grown to be transplanted—an operation which continues into July. The site selected for a tea-garden should be comparatively elevated land, for it is essential that water should not lodge round the roots of the plants. In Assam, which may be taken as the typical tea district, the most favourite situation is the slopes of low hills, that everywhere rise above the marshy valleys. On the summit may be seen the neat bungalow of the planter, lower down the coolie lines, while the tea bushes are studded in rows with mathematical precision all round the sides. The best soil is virgin forest land, rich in the decomposed vegetable matter of ages. Great pains are expended to prevent this fertile mould from being washed away by the violence of the tropical rains. In bringing new land into condition, the jungle should be put down in December, and burned on the spot in February. The ground is then cleaned by the plough or the hoe, and marked out for the seedlings by means of stakes planted at regular intervals of about four feet from each other.

For the first two years, nothing is required except keeping the plant clear of weeds [and hoeing round the roots.—ED. *I. T. G.*] Afterwards, it is necessary to prune the luxuriant [Why "luxuriant?" A two year old plant does not present a very "luxuriant" aspect. "Pruning" is to *develop leaf*, and to prevent the bush growing into a tree.—ED *I. T. G.*] height of the bushes in the cold season of every ensuing year. The prunings should be buried round the roots of the plant for manure. The plants begin to come into bearing in the third year, and gradually reach their maximum yield in their tenth year. The produce consists of the "flushes," or successive shoots of young leaves and buds, which first appear in the beginning of the rainy season. There are from five to seven full flushes in the season from March to November. The bushes are picked about every ten days by women and children, who are paid by weight on bringing their baskets to the factory,† when the operation of manufacture forthwith begins. The leaf is first spread out lightly on trays or mats, in order that it may "wither," *i. e.*, become limp and flaccid. Under favourable conditions, this result is effected in a single night; but sometimes the natural process has to be accelerated by exposure in the sun or by artificial heat. The next operation is known as "rolling," performed either by the manual labour of coolies or by machinery. The object of this is to twist and compress the leaf into balls, and set up fermentation.‡

* It will be observed that Dr Hunter applies the term *varieties* to two plants so different as the Assam and China teas, and yet he calls the cross between them a true hybrid. From the full and permanent fertility of the latter, our own strong inclination is to go counter to Mr. Owen's conclusion, and to recognize the parents, however different in habit, as only well-marked varieties.—ED.

* When thickly planted and well-cultivated, the returns are good.—ED.

† Dr. Hunter has been misinformed here. This is not always the rule.—ED. *I. T. G.*

‡ This is not the case. Rolling is to give the necessary twist, and for the purpose of breaking or bruising the numerous diminutive cells of which the leaves are constructed, in order to induce chemical action to take place, the result of which is the product called tea. Balling is to *fix* the twist of the leaf, and to promote more rapid fermentation—not to *set up* fermentation, which would take place any how. Sometimes there is no balling at all, if the leaf has been well rolled. We have often seen the rolled leaf as it came out of the machine simply piled up on trays and covered over with a cloth; but it takes a little longer to ferment thus, though it saves labour somewhat.—ED. *I. T. G.*

The final stage is to arrest fermentation by drying, which may be effected in many ways, usually by the help of machinery. The entire process of manufacture after "withering" does not take more than about four hours and a half. All that now remains to do is to sort the tea in sieves, according to size and quality, thus distinguishing the various grades, from flowery pekoe to broken congou, and to pack it for shipment in the well-known tea chests.*—*Hunter's "Indian Empire."*

MANITOBA:—A SAD PICTURE.

A planter writes:—

"If you would publish the enclosed cutting from the *Money Market Review*, it might be a warning to many men who are thinking of leaving Ceylon for Manitoba."

TO THE EDITOR OF THE "MONEY MARKET REVIEW."

SIR,—I read the letters (in reply to mine) of your correspondents, "S. A." and "H."

In reply, I repeat, "the country is simply a fraud; the climate renders it unfit for man or beast." "H.," in saying "the glass never reaches the limit" I gave, must be dreaming. I copy from our own *Globe* of 3rd February 1880, as follows:—"Register kept by the son of a Canadian clergyman *in his office* in Manitoba:—

Dec. 10th,	below zero	26	Dec. 17th,	below zero	48
,, 11th	,,	38	,, 18th	,,	42
,, 12th	,,	48	,, 19th	,,	43
,, 13th	,,	48	,, 20th	,,	38
,, 14th	,,	28	,, 21st	,,	52
,, 15th	,,	45	,, 24th	,,	56
,, 16th	,,	45	,, 25th	,,	43

So if you take, say, the 24th December, the glass registered 88 degrees below freezing!!!

"S. A."'s nephew writes that the wheat there is "as good, if not superior," to that of some of the States. This confirms my views, but is within the mark. Manitoba wheat is the finest in the world. I enclose two samples cut there on the 13th August last, perhaps the only samples (except what I keep) in ear from that country in Europe. But, I repeat the railways will prevent the wretched farmers from keeping even body and soul together. *I have seen this done* too often—to my cost.

As to 'large numbers of Canadians going to Manitoba, as also emigrants from the United States,' it is perfectly true, but do not let the British public suppose they go to farm!! Their sole reason is to extract the coin which English emigrants are (delusively induced) taking out with them. As a proof of the baits held out to speculators, I may say that town lots are selling today in Winnipeg for a higher price than they are in London streets.

Lastly, I own large properties not a thousand miles from Winnipeg, and have worked them with abundant capital and machinery as a farmer. The result is that I find farming will about pay expenses, crediting the farmer who works hard with the wages of a day labourer. My lands are left to utter neglect now, because I cannot sell; just now railways induce purchases by selling on "long time" and the unfortunates do not see the awful pit into which such bargains lure them. Nothing would induce me to live above 42 degrees.

"City" life in the North-West is not so bad, because you have amusements, and can stay indoors, but when the question resolves itself into causing gentlemen, ladies and children, to take up land in the bleak prairies, it is nothing short of murder. I repeat, deliberate murder. I could instance many deaths from exposure there—one of an English cavalry officer, two years ago, who went outside to cut wood. His wife found him an hour after frozen to death—she and her poor children left there without a sixpence.

Let "S. A." and "H." refute *one* of my statements, and I will say no more. The "bubble" is almost daily the theme of many who have been there and returned. I meet them constantly, and all deplore what is going on.—I am, sir, &c., F. F.

London, May 6th, 1882.

* What does Dr. Hunter mean by "the well-known tea-chests." Is the Indian tea-chest "a thing of beauty nd a joy for ever"?—ED. *I. T. G.*

THE BRAZILIAN COFFEE EXHIBITION AT THE CRYSTAL PALACE.

Our last number contained a full report of the banquet given by the Brazilian Consul-General in London. Mr. J. L. C. de Salles, on the occasion of inaugurating the Coffee Exhibition, by samples of that article drawn from the various sources of its growth in Brazil.

In addition to the steps taken by Mr. de Salles, thus far noticed, we may mention that he has made arrangements in the building of the Consulate for the exhibition of a large number of the different sorts of coffee sent for this purpose, in their original state, in order that brokers, merchants, and others may inspect and taste them, thus judging for themselves as to the popularity that Brazilian coffee is gradually assuming amongst those of other producing countries. Moreover, and, in order that this should be more fully known, the Consul-General has taken the trouble to distribute over England some hundreds of samples of the coffee already roasted, in japanned tins of three or four pounds each, the result being a great demand for more trials; indeed, everything possible is being done to bring this important subject fully under public notice. We have ourselves been favoured with one of these packages, which we shall turn to the best account.

One of the drawbacks to which the consumption of coffee in this country is exposed may be said to be the difficulty in finding competent coffee-makers. In the first place, as regards its quality, we believe that, with all the revenue restrictions as to the use of chicory only as a mixture, coffee is very extensively adulterated in other ways before it reaches the consumers' hands, and in the next place, little care or attention is exercised with it for daily use, even in well-regulated family circles, whilst for wholesale consumption in coffeehouses, or out of doors, a compound is too frequently produced of anything but an agreeable nature. In France, on the Continent, and in the United States, the principle is better understood, and what is called "café noir" or "café au lait," the latter used with good milk, are amongst the most healthy and agreeable of beverages, the latter particularly so for labouring men going to their work in the morning; "café noir" is used more as a luxury or *bon bouche*, but in both cases the requirements of the consumers are studied. John Bull is too apt to take things by the name they are called, whether coffee or tea, and not to question the particular ingredients, otherwise the consumption of coffee amongst us ought to be much more on a par with the extent of population; true it is that beer and alcohol enter more largely into this category of beverages, and it will take a long time before this habit is changed.—*South American Journal.*

CINCHONA GROWING AND HARVESTING.

(From the *Planters' Gazette*, June 1st.)

Mr. Teare, manager of the Neilgherry Tea and Cinchona Company, has recently been employed to inspect the several estates owned by the Wentworth Company, and from what he says it is quite evident that the soil and climate of the Wynaad are most favourable to the growth of *C. Succirubra* and *C. Condaminea* at all events, whilst the more valuable *Ledgeriana* has only been less successful apparently because the particular locality on which it was planted had not been well chosen. Writing of the Kanambyle estate, Mr. Teare says;—"The four to six year old trees are chiefly *Succirubra*, but there are large numbers of hybrids varying in almost every gradation and degree between *C. Condaminea* and *C. Succirubra*. Experience will probably prove that most of these hybrids are superior in quality of bark to the pure *C. Succirubra*. There is one tree on Kanambyle of wonderful growth, which approaches very closely in appearance the valuable *C. Condaminea*. The growth of the cinchona trees now under report is most highly satisfactory; many of these are over twenty feet high, and I have not seen in other parts of South India any which, taken as a whole, and allowing for difference of age, can compare with these beautiful forests at Kanambyle. It is not that individual trees have attained, in solitary instances, an abnormal size, but that all the trees are well developed. Most of the trees on this group are now ready to yield a crop of bark; each tree is estimated to give an average of four ounces of dry scraped or shaved bark. The scraping or shaving process will be the most advantageous for the following reasons: 1. A larger amount of bark per tree will be obtained. 2. Bark harvested on this system is of higher value than if taken in strips. 3. If operated on with care, and protected with grass, the trees suffer little deterioration in growth. 4. The bark will renew over the entire stem surface within one year, and will consequently give a larger and more valuable subsequent return than can be procured by any other process at present known."

Mr. Teare is very decided as to the desirability of commencing to bark *C. Succirubra* and its varieties while the trees are young. The best authorities are, he declares, of opinion that as the bark grows older and woody fibre replaces cellular tissue, the alkaloids already in the bark appear to turn into resin and gum, or colouring matter, and the bark secretes in that part of it no fresh alkaloids; the result is the bark (of *C. Succirubra*) deteriorates with age.* This last remark refers only to trees that have never been barked. He is also in favour of thinning out the young plantations in order to allow space for the growth of foliage necessary for the nourishment of the stems. "Leaves," he says, "perform a much larger share in the economic development of vegetable life than is generally supposed. They contribute more to the organic bulk of trees than the roots do; one hundred pounds of dry wood give only from half to one pound of ash or inorganic matter when burned. The ash represents the proportion of material absorbed by a tree through its roots; the remaining ninety-nine pounds of dry wood have therefore been obtained through the leaves, chiefly in the form of carbon. For these reasons I advise that in some places every alternate row of trees should be coppiced."

With reference to the preparation of bark for shipment, the following remarks contain a hint which may prove useful to any experienced managers:—

"The most favourable season for taking crop from cinchona being during the monsoon, when the atmosphere is saturated with moisture, and rain is constantly falling, it is necessary that means should be devised for drying the bark by heated air. Solar heat cannot be relied on during the monsoon. I therefore advise that a building should be erected for this purpose in readiness to receive the wet bark (from which from 55 to 65 per cent. of moisture must be driven off). Machinery can probably be used for this purpose with great advantage, in regard to saving of time, space, labour, fuel, and money." We may add that so far as can be ascertained here no appliances specially designed for artificially drying bark have yet been invented, but that apparatus manufactured by Messrs. J. Gordon & Co. for drying cocoa and coffee seems likely to answer the purpose admirably. It consists of a store having an upper floor, on which strong galvanized wire netting is spread over the joists. On the ground-floor there is a furnace fitted with a hot-air chamber, and an iron pipe runs from it under the wire netting, and by this means hot air is rapidly diffused through whatever is laid thereon. There is also a fan, by means of which the moisture is carried off, and a regular draft maintained. The cost of the whole apparatus for a floor 30 feet by 15 feet (exclusive, of course, of the building itself), does not exceed £50. This system has proved very successful in practice with cocoa and coffee, and we would think it still easier to extract the moisture from cinchona bark shavings.

[The Cleribew system is the one referred to, but query whether cinchona bark, shavings at any rate, could not be prepared in the "Siroeco" tea-drying machine?—Ed.]

MR. D. MORRIS ON CACAO (OR COCOA).

On Tuesday evening (9th May) Mr. D. Morris, M.A., F.G.S., the Director of Public Gardens and Plantations, delivered at the townhall the fifth of the present series of lectures under the auspices of the Jamaica Institute. His subject was: "Cacao; how to grow and how to cure it." The Hon. Alan Ker was called to the chair, and introduced the lecturer to a very large audience. The ladies were not numerous on this occasion, but there were in the Hall plenty of agriculturists who were anxious to be informed authoritatively whether money could be made in cacao.

Mr. Morris, who was surrounded by the illustrations which we enumerate below, said that by its soil, climate and varying altitudes Jamaica was naturally the home of a varied culture, and that it was necessary, in order to secure a permanent prosperity, to plant many things, and not "to carry all the eggs in one basket." Although sugar-cane cultivation would, he believed, always be extensive here, on account of the good opportunities presented for it, that cultivation had by means of the old conditions of the island been carried into localities whose elevation, &c., rendered it impossible that it could be profitable under existing conditions; and it was therefore expedient to look around for new industries. The island with a varied agriculture would be safer against fluctuating markets, depression of certain industries, and visitations which so often afflict economic plants—coffee, cane, cotton, tobacco, wheat, &c. There was, in his opinion, no reason why the cultivation of cacao in Jamaica should not become as great as that of cinchona, now so full of promise, and so energetically pushed.

The cultivation of cacao here was increasing rapidly. The present export was valued at £10,918 for 1880, the quantity being 3 304 cwt. as compared with an export only 14 years before of but 133 cwt. Mr. Morris quoted extensively from old historical writers, Edwards,

* Certainly not until after the 10th year, if then. —Ed.

Long, and others, to show that in the seventeeth century, cacao in Jamaica was very generally grown and was of great importance among the exports. But it declined on account of "blast" or hurricanes and of the excessive duties imposed upon it in England, amounting to 480 per cent of the value. The demand for cacao, in response to which the cultivation had been resumed here, was increasing every day, the annual consumption of cacao, being now from 100 to 110 million pounds. Although not a cacao "plantation' can be found in Jamaica the foundations of a new cacao industry are being laid. Mr. Morris, in giving a sketch of the history of cacao, stated that a member of the family was said by Martius to be a native of Jamaica. It was known as *Theobroma sylvestre* and grew wild. Its presence now is doubtful, but the fact, if verified, would tend to encourage those who were embarking in the enterprize, as proving that the island possesses the initial elements of soil and climate for the successful cultivation of cacao.

Mr. Morris gave a long and interesting description of the various kinds of Theobroma cacao, as Linnæus named the tree, and showed the manner of its growth from plants on the platform. He called attention to the fact that he had already recommended for Jamaica the cultivation of the best kinds of Trinidad cacao and he insisted on the necessity of growing only cacao of the best quality. Speaking of the forastero cacao now grown in Trinidad to the exclusion of all other varieties, he said that unfortunately "of the kinds already established in Jamaica, the calabacillo (the lowest quality of forastero and never cultivated by a careful Trinidad planter) being the hardiest has unfortunately survived in remote places, and I fear is being largely cultivated by settlers under the impression that all cacao of whatever variety is equally good." Happily from 20,000 to 30,000 of the best Trinidad varieties have already been distributed to planters in Jamaica, and it is hoped that when these have fruited there will be a supply of seeds available for thoroughly establishing the most valuable kinds in the island.

In treating of the cultivation of cacao, Mr. Morris observed, that as concerned temperature and rainfall, some of the plains and valleys of Jamaica were no doubt admirably adapted for the cultivation of cacao. "Although Jamaica is about 7½ degrees further north than Trinidad and nearly 6 degrees further north than Grenada, it is almost in the same latitude as some of the best cacao districts of Mexico and Guatemala." A consideration of the facts connected with climate, latitude, &c., led him to the conviction, however, that in Jamaica the successful cultivation would be confined to the moister valleys and hollows, up to 500 feet, well protected from winds. Cacao was already apparently at home in glades among the St. Andrew Red Hills, in the Wag Water Valley, in the Bath and Plantain Garden River districts, and in many parts of St. George and Portland. The rainfall should not be below an average of 60 inches per annum, nor the mean annual temperature below 75 deg. Fah., and the soil should be deep and moderately rich, the preference being given to that containing a certain proportion of lime or marl.

Mr. Morris proceeded to give directions as to selection of land, cleaning, planting at stake and from nurseries, shade trees and timber belts for shelter, the treatment of the plant until bearing time came, pruning, weeding, manuring, the best methods of picking and malting and preparing for market, &c. For shade in Jamaica, he approved bananas, and the sandbox tree in place of the Immortelle hitherto patronized in Trinidad. He condemned strongly the present processes in vogue here for washing and drying cacao, and recommended the Trinidad curing houses, models of which he exhibited, for the purpose of sweating the beans. He also called attention to the claying of the beans, for which the red earth of Jamaica was very suitable. The adoption of the improved methods would add thousands of pounds yearly to the value of Jamaica cacao.

The lecture was illustrated as follows :—

Diagrams—(1.) Plan of cacao estate, first year.

(2.) Varieties of cacao.

(3.) Return of cacao shipped from Jamaica, 1875-80.

(4.) Coloured drawings, shewing leaves and flowers of cacao tree; flower magnified; Forastero, *Colorado* and *Amarillo* varieties of fruit—method of cutting fruit—cacao hook.

Models—Cacao house for 300 acres; ditto for 10 acres.

Cacao hook for gathering crop.

Samples:—Cured cacao—"Caracas"—"Trinidad"—"San Antoni."—"San Jose"—"Good Red"—"Good Ordinary"—"Jamaica Cacao"—Clay for curing cacao.

Specimens:—Criollo—Forastero—*Amarillo, Colorado, Truxilliano, Amelonado, Calabacillo.* Varieties of Jamaica-grown cacao—Growing specimens of cacao and Immortelle trees.

At the close of the lecture, the Hon. G. Henderson, Mr. Francis of Cedar Valley Mr. Harrison, the Rev. Mr. Downer and Mr. Kelly Smith spoke on the subject. A vote of thanks was passed, in the usual way, for the lecturer.—Jamaica *Weekly Gleaner*, 11th May 1882.

CACAO (COCOA) CULTIVATION IN JAMAICA.

We are sanguine enough to look for very happy and beneficial results from the lecture upon cacao cultivation delivered by Mr. Morris on Tuesday night at the Townhall. In our opinion the lecture is destined to give a stimulus to this cultivation commensurate with the stimulus given to cinchona by the earlier efforts of Mr. Morris. People who have not been through the mountainous district a few miles out north of Kingston and including St. Catherine's Peak and Blue Mountain, can hardly conceive of the vast extent of private land now under cinchona, but which before the arrival of our present hardworking Director of Public Gardens and Plantations was literally a burden on the owners. What has thus been done for the hills, Mr. Morris offers to do for the valleys, and he advocates that between the sugar of the plains and the cinchona of the peaks should come Liberian coffee to supplement the Arabian coffee and cacao cultivation to go hand in hand with banana cultivation. It is most encouraging to learn from a competent judge who, as his lecture showed, has taken infinite trouble to study the subject, that Jamaica presents a favourable field for cacao.

All who are interested in cacao cultivation here, or desire to become so, will doubtless obtain the lecture for themselves, in full, as early as possible, and take advantage of its practical instruction. We may remark that Mr. Morris points out how, from the very hour when the seed is dropped and the plant begins to grow, the present methods of the cacao industry in Jamaica may be improved. The piece of advice which is especially striking is that with regard to curing. We appear to be wholly in the wrong in Jamaica in the manner of preparing cacao for the market, and the sooner scientific methods are in vogue here the better it will be for the cacao growers and the reputation of their product. Mr. Prestoe, the Botanist of Trinidad, in his last report, speaking of the old, careless process of curing, advocates the same system as Mr. Morris does, and says of the cacao under the old system that, by the time it is shipped, it is only little better than decayed vegetable tissue.

Mr. Morris, although he does not promise that, by improvement all round, Jamaica cacao can obtain the price of the Trinidad "San Antonio," from 105s to

120s per hundredweight, is very confident that, if properly grown and prepared, it would easily find a market at 80s, which is a price far beyond any now attained. But he points out that, while in Trinidad the cacao field yields no profit on its low shade trees, in Jamaica the banana will give good shade and provide fruit to meet the increasing demand in the United States. In Grenada, where cacao is also successfully cultivated, the growers suffer, we may here state, from an evil which is at least as bad as our high winds. Mr. Ober in his "Camps in the Caribees," recently published, says of the cacao cultivation in Grenada:—"Happy and contented as the negro may be in his wealth of cacao trees, he is sometimes enraged at the depredations committed by the forest quadrupeds, for the rats, not content with the succulent cane, eagerly seek out the sweet pulp of the cacao. Where monkeys are abundant, as in Grenada, they commit great havoc, not only gnawing holes in the pods as they hang on the trees, but carrying away all they can hold in their arms. In one of my monkey-hunting excursions I stopped at the house of a very agreeable planter, in the mountains. He declared that one year the monkeys nearly destroyed his crop: and not only ate the cacao seeds, but brought the empty pods and placed them on his door step, thus adding insult to injury. [Oh!—ED.] * * * I have seen heaps of cacao pods, each with a small hole in it an inch or so in diameter, where the monkey had thrust in his hand to scoop out the pulp." In Jamaica, the mongoose will kill the rats, and we have no monkeys. Country readers will be glad to learn that the Government will print and issue Mr. Morris' lecture for public information at once.—*Jamaica Weekly Gleaner.*

VARIETIES OF LIBERIAN COFFEE.

The uniform type of the Arabian coffee in Ceylon has been maintained so completely, that any variation of habit and appearance, beyond that caused by soil and treatment, has been of the rarest occurrence. The planter therefore accustomed to the cultivation of this species was little prepared for the boundless variety of the Liberian species, that runs from the fishing-rod on end, with a crow's nest on the summit, to the dwarf, that on thirty inches of stem has crowded eighteen pairs of branches, the lowest and longest of which only measure fifteen inches. Again the different specimens differ from each other in every possible way: taking one hundred plants grown from imported seed, put out on the same day, in the same soil, and treated exactly the same in every way, for two and-a-half years, there is a vast range of variety in the height at which they begin to branch, running from one foot to three or more; in the regularity of their branching: one topped at six feet having thirty-four primaries, while its neighbour topped at seven feet has only seventeen: one may have short, stiff erect branches, while another close by will have them running out almost horizontally, and five feet in length. Then there is a vast range in the size, form, and colour of the leaf, from 5 × 11 inches to 5 × 2, and from the deepest dark green to a dusky yellow. One will be a close mass of foliage, while the next, without having suffered from *Hemileia*, is so bare that one might count all its leaves without touching it. So, in crop-yielding qualities, they are as unlike as in other respects. One tree will have 400 ripe cherries, and 3,000 of others in various stages, while its neighbour has not 100 altogether; one has long foot stalks, that allow as many as 25 cherries to come to maturity in a single cluster, while another is so short, that half that number cannot possibly survive the pressure. The fruit of one tree is globular; of another oval. One tree ripens its fruit as perfectly as the Arabian species, while the cherries on another only change to a brownish yellow, crack, and dry on the branches.

Out of all these varieties it is enough to reject for propagation, all the inferior castes, the stragglers, the long-jointed loose-leaved kinds, the upright-branched, every one of which gets the fungus early, and never shakes it off, specially the long-legged kinds that always take "a list to leeward where wind blows, and gives so much to bare stem, that they have not room left, within cultivable height, for a fair amount of bearing wood. The first quality to be desired in a Liberian coffee tree is the power of resisting the fungus. There is no certainty that this resisting power is a hereditary quality, but the best practicable course is never to take seed from any tree that has ever exhibited a pinspot of *Hemileia*. The other qualities to be desiderated are low branching, full, dark foliage, good bearing quality, a long fruit-stalk, an oval rather than a globular fruit, long spreading branches, instead of short ones loaded with secondaries and tertiaries before a crop is gathered, and the capacity of fully ripening its crop within the year. We are acquainted with no one variety that combines all the qualities we want in this model tree, and, therefore, among those that have hitherto resisted the fungus, there is no choice; for, if this plant, or that, has one or two of the qualifications that satisfy, they are probably deficient in others equally important. So far then as our observation has gone, we have not met with one plant, that combines all the qualities desired in Liberian coffee; but there are three, perhaps four, varieties that come pretty close to perfection without reaching it, and any one of them will be a tolerably satisfactory plant to cultivate, unless one still undecided question should in the course of extended experience receive an adverse answer.

We have no assurance that a plant that has run into such wide variety in its habitat will keep true to the type of the immediate parent elsewhere. Certainty on this point can only be reached by patient experiments, extending over five or six years, but there are already facts available that seem to militate against the favourable side of the question. We cannot suppose that either Liberia or Udapola supplied their customers with seed from trees of "fishing-rod" style, yet from both we have seen specimens of that remarkable variety. The plants sent to Ceylon by Mr. Bull were all of one kind (though not the best kind, we now have in Ceylon); yet from Mausava seed there has been no uniformity of development. One plant branches at eighteen inches, and another runs up above three feet, without a branch, and what other diversities may hereafter occur we cannot say. There can be no doubt that, if we select seed from the best kinds, and systematically destroy all the weaker kinds, as soon as they manifest their qualities, we will arrive

at a satisfactory variety in the end; but there is an element of doubt in the result, even when the seed of the best varieties alone are used, so long as the comparatively worthless varieties are permitted to remain side by side with the valuable kinds. Whenever two or more varieties of one species grow together, cross-fertilization will almost certainly result, leading to a still further multiplication of variety.

An experiment is proposed to be tried as follows:—To select seed from the four varieties that have among them all the good qualities required. Plant them in a field by themselves, as far as possible from any other coffee, and surrounded by some extent of jungle. As soon as any plant begins to manifest bad qualities, weed it out, so that in a couple of years none but the best varieties will remain. The prospect would then appear to be favourable to the hope that such treatment would yield varieties not inferior to the immediate parents, and in all probability superior to any we now possess, none of which have all the qualities that go to make up perfection. Many of the smaller variesties are early and heavy bearers, but some of them are unequal to the ripening of their crop, and nearly all of them are specially weak on the fungus point. There is one rather common variety, with short, stiff, upright primaries, not one of which escapes infection, and, from the day on which it is attacked, it ceases to be a factor in the prospective success of an estate; it only stands among better kinds a leafless skeleton, and every fresh leaf it struggles to produce is met by the enemy as soon as developed. There are others of larger frame, but of an open straggling habit, that are not much safer from the fungus, and are much inferioras crop-bearers. Of the varieties most worthy of the planter's attention, we place on record the following notes of two distinct types planted on 7th November 1879:—

Topped at 6 feet	No. 1 ...	No. 2. 7 feet
Primaries 34	... ...	„ 17 „
Length of primaries	3 feet 9 inches	„ 4 „ 6 in. high
Branched at	I foot high ...	„ 2 „ 5 in. „
Size of leaf	9 in × 3½	„ 11 in. × 5
Crop all sizes	3,500 cherry ...	„ 1,500

No. 1 has nearly all the good qualities to be desired; the leaf is only rather narrow and the fruit-stalk short. No. 2 is a straggling plant of its type, but its vast leaves, its bold, long, and strong primaries, with their wealth of fine, healthy secondaries, and the general vigor of its appearance, render it one of the safest kinds to propagate.

It will be interesting to have this experience compared with that obtained by other planters of Liberian coffee in the Western, North-Western, Southern and even Central Provinces of Ceylon. There can be no doubt of the great variety of coffee imported from West Africa under the name of 'Liberian' in the early days of the pioneering enterprize, for, as Mr. Shelton Agar saw during his trip to Liberia, every size of bean was available from the small pea-like St. Thomé coffee up to the largest size of Liberian cherry. The planters who are beginning operations in Ceylon with the carefully selected seed now made available from the best trees, may be congratulated on the advantage they will thus have over pioneers who had to take the imported seed very much as it came to their hands.

PLANTING IN JOHORE.

To the Editor of the [Singapore] *Daily Times.*

DEAR SIR,—My attention has only lately been called to the letter which appeared in your issue of the 29th ult., signed "Coffee," republished from the *Ceylon Observer* and to the correspondence which it called forth in your columns. Having had upwards of eleven years' planting experience in Ceylon, and having been for some time engaged in planting in Johore, I venture to offer my opinion on the subjects referred to by "Coffee" and your correspondents. "Coffee" says that every Ceylon planter of experience who has visited Johore has condemned it. This is not correct. I could name several Ceylon planters of experience besides myself, who, so far from condemning Johore, have pronounced that it is excellently adapted for the cultivation of lowcountry products. "Coffee" refers to Mr. Dobree as being of the same opinion as himself. Mr. Dobree no doubt stated in his report that Pulai was at too low an elevation for the successful cultivation of *Coffee Arabica*, but he also stated that, in his opinion, other products, such as Liberian coffee, tea, pepper &c., could be grown successfully. Mr. Dobree also spoke highly of the soil and its capabilities for the cultivation of lowcountry products. There is little doubt, indeed, as to the success of tea, Liberian coffee, cocoa, pepper, sago and sugar, for these are now beyond the experimental stage, and if it should turn out that *Coffee Arabica* cannot be grown to pay, either in the open or in the shade, we have the satisfaction of knowing that the other products can.

My experience of Johore is that the higher you go the poorer the soil becomes. Fortunately there are but few mountain ranges, the country consisting for the most part of undulating land, which in Ceylon would be described as "lowcountry" and the soil is as good as if not better than the average Ceylon soil.

With regard to labour, I do not know what they pay in Batu Pahat, but I pay from $4 to $6 a month, and I believe my neighbours do the same. By advancing from $12 to $15 a head, we can get as many coolies as we require at $5 a month. The cost of felling is considerably less than in Ceylon, and other works, such as holing, filling in, piling, burning, &c., can be done nearly as cheaply here as in that island. It should be borne in mind that this country is new to planting experience, and that probably in Ceylon labor is cheaper than in any other country in the world. I see from the *Observer* that in Fiji each cooly costs the planter from £16 to £22, and that in Queensland Messrs. Poett and Mackinnon are paying their Chinese labourers £1 per week!! In Johore, on the other hand, I consider that we do not compare unfavourably even with Ceylon.

As to roads, it must be remembered that Johore is still in its infancy so far as plantiug is concerned. The roads are therefore few, the natives generally living near the river. The river communication, however, is so ample that the need of roads is not felt as it would be in Ceylon. Nevertheless, many miles of roads have already been made and many more are in course of construction. The existing means of communication are sufficient for our present wants. If at any time a European has to go any distance, the Maharaja, who is a most kind and hospitable prince, is always willing to lend him one of his steam launches.

The future success of planting in Johore is, I think, well assured, and is only a question of time. When the acreage at present under cultivation comes into bearing, the public will be able to judge of its merits; and I think there need be little fear of the result.—I am, &c., L. C. P.

Johore, 15th June, 1882.

PARAGUAYAN TEA.

TO THE EDITOR OF THE "BRITISH TRADE JOURNAL."

SIR,—With reference to your correspondent's letter in the April number of the *British Trade Journal* on the subject of Paraguayan tea, I may say that the objection to Yerba Mate is common to beginners, as with smoking. But all Englishmen who have lived in South America will tell you that they very much miss the Yerba Mate here. It is, in time, a most greatful, and, beyond all question, a most healthy and invigorating beverage. Gauchos work cattle all day without

other food, not eating till sunset. It was banned in this country under Queen Anne out of hatred to Spain (or to the Jesuits), the doctors declaring that it was an enemy to the fecundity of the human race. Such effects have never been noted in South America, where barrenness is exceedingly rare.

It is not to the interest of the tea-merchants or the revenue that we should get Yerba at a penny a pound, but whenever Yerba becomes common here we shall have fewer prisons, lunatic asylums, &c., as "drink" will be on the decline.

Jesuit's bark (cinchona) has proved a business to mankind, and the tea that bears their name may one day be almost as much valued.

If the doctors of Queen Anne's day had not been insanely prejudiced, or, perhaps, bribed by the tea-merchants, we should now have Yerba Mate in as general use here as in South America. The Irish sheep-farmers in Buenos Ayres take it with sugar, but if you can take it pure it is better. I like it *amargo*, in all its purity, just as much as I relish a cigar.—Yours truly, ANGLO-PORTENO.

London, May 8th.

MR. D. MORRIS ON THE VARIETIES OF CACAO (OR COCOA.)

Our readers interested in the cultivation of cacao will be pleased to see the letter from the late Assistant Director of our Botanic Gardens, in which he summarizes information collected during a visit to Trinidad and given in full detail in a lecture which he recently delivered in Jamaica. The main points are that there are two great varieties of the cacao,—the creole and the foreign. "Creole" is a term employed in the West Indies, not (as many think) as the equivalent of half-caste, but quite the contrary: a person, colonial born, but of pure descent. In regard to natural productions the term seems to have the same sense as indigenous. In the case of cacao, the belief is that the fine but delicate "creole" coffee was the only variety cultivated in Trinidad, until a "blast" or hurricane wrought such destruction that a foreign kind was introduced, which compensates by its robustness for some inferiority of quality. In the two main varieties, however, there are almost endless subvarieties, and no doubt, the plant is specially amenable to the effects of careful cultivation. In this way what are deemed inferior varieties in South America or the West Indies may develope superior qualities in Ceylon. Indeed, they seem to have done so already, and although the Caraccas kinds, especially the pale one, are described as of superior quality, it may be that like Ledgeriana amongst the cinchonas and indigenous Assam amongst the teas: delicacy of constitution and consequent difficulty in cultivation may attend the choice of such superior varieties Our planters will, of course, try all the existing kinds, and it is probable they will in time develope a Ceylon hybrid or variety of a specially good type. Meantime the proper preparation of such beans as are produced seems to be quite as important as the choice of kinds to cultivate. As yet, such small parcels of the Ceylon beans as have reached the market seem to have been well prepared and of good quality, and we trust no effort will be spared to preserve the good reputation of Ceylon-grown cacao. On that product, with Liberian coffee, tea and cinchona, the future of the island and its enterprize and industry seem now largely to depend,—although we do not despair of the revival of old King Coffee of Abyssinia *via* Arabia.

MR. D. MORRIS ON THE TWO CLASSES OF CACAO: *C. CRIOLLA* AND *C. FORASTERO*.

Botanical Department, Gordon Town,
Jamaica, 22nd May 1882.

SIRS,—Having lately returned from a six weeks' trip to Trinidad and the Southern Islands for the purpose of looking up cacao cultivation, I gave the results in a lecture before the Institute of Jamaica, particulars of which will be found in the accompanying papers.

The lecture itself will be shortly published, and hence it is unnecessary for me to enter into any minute details at present. There are, however, one or two points relating to cacao in Ceylon from what I gather in your valuable publications—the *Overland Observer* and the *Tropical Agriculturist*—which deserve some attention; and I would mention them in the hope of throwing some light on the relative merits of the varieties now under cultivation there. So far as I have been able to gather, all the varieties of cacao cultivated in the West Indies and Venezuela may be grouped under two large classes, viz., CACAO CRIOLLA and CACAO FORASTERO. *Cacao criolla* was formerly the only kind cultivated in Trinidad, but, according to M. Joseph, in his history of Trinidad, a blast* affected the plantations to such an extent that the cultivation was almost ruined.

This result was attributed at the time to the delicate character of the *cacao criolla*, which in addition was said to be a poor yielder and unsuited to the climate. Under these circumstances, the more robust and hardy *cacao forastero* (literally foreign cacao) was introduced, and of late years this has entirely supplanted the *cacao criollo*.† In fact, with the exception of some two or three trees here and there (one of which was pointed out to me by Mr. Prestoe in the Botanical Gardens) there is practically now no *cacao criolla* in Trinidad. It is chiefly confined at the present time to the mainland of Venezuela, and it doubtless yields some, if not most, of the celebrated Caracas cacao of commerce. The pods in this kind are of a red colour and smaller than those of the Forastero class (generally about 6 or 8 inches long). When young, the end next the stalk is somewhat constricted or narrowed; the other end is pointed and slightly turned to one side. The chief difference, however, exists in the seeds. These are much thicker than in any other kind of cacao I am acquainted with; very short, almost globular, and with the interior (when fresh) of a pale, crimson colour.

The produce of *cacao criollo*, when well cured, is of a much finer flavour than the more robust Forastero class. Possessing also a larger proportion of essential oil and less bitterness, it requires less fermentation and has better keeping qualities. As so much is thought everywhere of Caracas cacao, I have been endeavouring for the last two years to procure pods of all the best kinds cultivated on the Main, and, after receiving several consignments of fruit as well as cured beans, from La Guayra—the port of Caracas—and other places, I am inclined to believe that there is no distinctive variety which may be termed Caracas cacao other than what is known as Creole cacao. That is, Caracas cacao, if the produce of any well-defined variety, is probably that of *cacao criolla*. I may, however, be wrong in my supposition; but I give the result of my enquiries so far.

* A hurricane.—ED.

† The creole cacao.—ED.

Mr. Prestoe, I believe, agrees with me, for in a recent letter he remarks that as far as he is aware there is no variety of cacao peculiar to the mainland (Venezuela) which is not also represented in Trinidad.

With regard to *cacao forastero*, this class constitutes the bulk of the cacao cultivated in Trinidad, Grenada and the other West India islands. Its general characteristics are trees of robust, hardy growth and generally prolific in fruit: the seeds are somewhat long and narrow in the best varieties, but becoming flattish and angular in the lowest. The interior of the seeds when fresh are of a violet tint, as contrasting with the pale crimson of *cacao criolla*: they require generally longer time for fermentation, and, containing a somewhat smaller proportion of essential oil, they have not such good keeping qualities. In the best varieties, however, *cacao forastero* approaches very near *cacao criolla*; whereas for general cultural purposes it would appear, according to the experience in Trinidad, to be superior.

There are some twelve or fourteen varieties of *cacao forastero* known in Trinidad, each possessing well-marked characteristics as regards size of trees, requirements as to shade, yield of fruit, as well as quality of produce.

Owing to the contract system under which most of the estates now in bearing in Trinidad were established, the different varieties are so intermingled that it is impossible to keep them separate, and the produce is necessarily mixed and subjected to one uniform system of fermentation and curing.

This must result in some varieties being fermented too much and others too little. At present, however, there would appear to be no help for it, although some of the best planters are weeding out the worst varieties as they appear, and supplying their places with plants raised from seed of the best of the Forastero class. The following are the principal varieties:—

a—cundeamur verugoso amarillo*	... rough yellow.
b— ,, *verugoso colorado*	... ,, red.
c—liso amarillo	... smooth yellow.
d—liso colorado	... ,, red.
e—amelonado amarillo	... melon-shaped yellow.
f—amelonado colorado	... ,, red.
g—calabacillo amarillo	... calabash yellow.
h—calabacillo colorado	... ,, red.

The best variety of the Forastero class in the *verugoso amarillo* or "rough yellow," which is much esteemed both in Trinidad and Grenada as hardy in growth and prolific in fruit.

The shell is comparatively thin and the proportionate weight of seeds is much greater than in the other varieties. It is also said to require less fermentation. In this, as well as the *verugoso colorado* or "rough red," the pods are generally large; some fine specimens which I brought from San Antonio estate being 11 inches long, and fully 12 inches in circumference at the thickest part. The seeds are of the true almond shape and pale violet colour.

In the *liso* and *amarillo liso* and *colorado* "smooth yellow" and "smooth red" respectively, the fruits have somewhat the same shape and characteristics as the *cundeamur verugoso*, but the shells are thicker and heavier.

As the quality of the produce is not so good as in the *cundeamur verugoso*, there is therefore a waste of material without any compensation. Similarly with the *amelonado* or "melon shaped" varieties, of which again there are two forms, the yellow and the red. This latter holds a position midway between the *cundeamur verugoso* and the *calabacillo* or calabash varieties.

The *calabacillo* also of two forms (yellow and red) is the lowest variety of the Forastero class, and is never cultivated by a careful planter. This is sometimes called "wild cacao," but as it appears even among seedlings of the best varieties, it is evidently only a debased form of *cacao forastero*. The pods of the *calabacillo* variety are small, seldom more than three or four inches long; the seeds are flat, angular, intensely bitter, and of a dark violet colour. They are not improved by fermentation, and the market value of the produce is low.

I found among cacao plantations in Trinidad a tree here and there which the Spaniards termed "male" or sterile cacao. On these trees the pods, when produced, contained only a few small seeds, the central portion being generally nothing but pith. Whether this is a very debased *calabacillo* form I know not. The occurrence of these trees is, however, a subject which deserves some attention, if only to discover whether they in any way contribute to the better fertilization of the ordinary hermaphrodite flowers. If, on the other hand, they are purely debased forms, and do no service, they cannot be too carefully eradicated.

As far as I can remember, in Ceylon you have no true *cacao criolla*, unless it has been introduced lately. Whether it is advisable to introduce and cultivate it, when you can obtain such good results with the Forastero class, is purely a matter of choice. You have, no doubt, good Forastero varieties.

I shall glad to be find if the above notes will do something towards identifying these varieties and lead to their characteristics being carefully observed. If, as remarked by Mr. Prestoe, there is a difference of value between the varieties of cacao trees as to quality and productiveness of at least from one to three; and, if also in respect to the relative value of the pod to its contents (that is weight for weight) the difference ranges as one to five, there is evidently for the planter and especially in a new country, much to learn as regards the special varieties of cacao to cultivate and their suitability for different soils, aspects and climates.—Very faithfully yours,

D. MORRIS,

Director of Public Gardens and Plantations, Jamaica.

* Cundeamur is, I believe, the Spanish name for the fruit of the Cerasee, *Momordica charantia*, and this cacao obtains its name from the warted rugged appearance which it presents closely resembling the above-named fruit.

WYNAAD PLANTING AND MINING ASSOCIATION.

Notes of a Committee Meeting held at Pookote Club, Vythery, on Friday, 23rd June 1882.

Present.—Messrs. Batty, Punnett, Winterbotham, Fethertonhaugh and G. L. Yonge, Honorary Secretary. Mr. Winterbotham in the chair. The proceedings of the previous meeting were read and confirmed.

Roads.—Attention having been called to the unsafe condition of many of the bridges on the main roads, it was resolved that the president of the Malabar Local Fund Board be addressed on the subject.

Adulteration of Coffee.—Read letter from Messrs. Hinde & Co. with copies of their correspondence with the Madras Chamber of Commerce. Resolved that this Association will cordially co-operate with the Malabar merchants in memorializing the Home Government on the subject.

Beypore-Mysore Railway.—Read circular from Messrs. Pierce, Leslie & Co., the agents for the concessionaries of the proposed Railway, suggesting the free surrender of waste lands required for the railway. Resolved that the project has the most cordial support of the Association. The committee hope that each individual member will agree to the terms proposed and that the native landholders will recognise the advantage of co-operating.

Registration of Maisteries.—Read letter from the Honorary Secretary of the Coorg Planters' Association, inviting this Association to co-operate with them in a memorial to the Mysore Government to urge the enactment of an Act for the compulsory registration of all maisteries.

Resolved that the Honorary Secretary recall to the attention of the Coorg Planters' Association the efforts that

have been made for many years to get this most important matter attended to, forwarding them the printed correspondence on the subject and assuring them of our willingness to join them in any well concerted proposal.

Leaf-Disease.—Read communication from the Revenue Department, Government of Madras. Reporting that in consequence of the appearance of leaf-disease in the Island of Reunion the French Governor had prohibited the importation of coffee plants and berries from India.—Recorded.

CINCHONA GROWING IN BOLIVIA.—The following is an extract from a Bolivian official's report, and we present it to our readers as a sort of puzzle. All that we can make of it is that the cultivation of cinchona is spreading in Bolivia, a fact of which Mr. T. Christy has already made us aware :— "The plantations of quina are daily increasing very considerably throughout the Eastern Andes. The plantations established are as follows :— in Yungas 200,000, Songo 70,000, Maipiri 3,500,000, Guanay 32,000, Camato 30,000, Canpolican 10,000, making in all 3,842,000 trees, which may, perhaps, be further increased to 4,000,000, if the plantations of Challana were included in the estimate. Under the supposition that each tree will afford from six to eight *tons* (sic) of cascarilla, there would result for the planter a clear annual profit of from one to two bolivianos (about 3s sterling) for each plant, so that 4,000,000 trees at 5 bolivianos each represent a capital of 20,000,000 bolivianos. These trees, which at present are only from 5 to 10 years old, will arrive at their full state of development in from 10 to 15 years more, and will then represent a capital of 80,000,00 bolivianos, presuming the price of the bark to be 100 bolivianos per quintal (100ths.)"—*Planters' Gazette.*

THE RIO CHAMBER OF COMMERCE is evidently a practical and important body. We read in the *Rio News*:—The "Centro da Lavoura e Commercio" of this city has called meetings for today and the 17th for the discussion of the various questions relating to the development of agriculture and commerce. According to the *Cruzeiro* the subjects to be considered will be :— 1, reduction of export duties ; 2, commercial treaties in the interests of agriculture ; 3, revision of the mortgage laws to facilitate liquidation and augment real estate credit ; 4, practical means for promoting immigration ; 5, the pledging of agricultural products and valuables ; 6, agricultural premiums and the introduction of products ; 7, modification of railway tariffs. There is need, of course, of many vital reforms in the mortgage laws, but these should be undertaken in the interests of creditors, rather than for securing greater borrowing facilities. Just now there is a very dangerous craze over this question of agricultural credits. With the enormous burden of indebtedness now weighing upon the agricultural estates of this country, it is nothing less than madness to legislate further facilities into the planter's hands for increasing his indebtedness. What Brazil needs is more manual labor—not more debts. In the matter of immigration, there is food enough for a great many discussions. It is a question which involves, directly or indirectly, a reform in almost every class of laws in the country. It involves putting the emigrant to Brazil on a par with those going to the United States, to Canada, and to Australia, in the matter of religion, of education, of citizenship, of acquiring, holding and devising property, of Association, and of the many other things which tend to an emigrant's social and material well being. It's too broad a question for an hour's talk ; the "Centro" should begin it, and then follow it to the end—if it takes all summer. And so too with the question of railway tariffs—which might also include that of state administration. As a rule, the tariffs in this country are much too high, and they can well be reduced in the interests of all parties concerned.

NEW PRODUCTS : INDIARUBBER CULTIVATION.

Attention may be directed to the very encouraging remarks in the last letter of our London Commercial Correspondent in respect of rubber culture, and these remarks as well as the letters of Mr. Christy and "Nemo Nomad" reach us as we receive very satisfactory reports of the growth of the tree in several Ceylon districts. The almost unprecedented windstorms which have swept over parts of the hill-country lately have affected some of the trees, snapping off the tops ; but this is exceptional, and, so far as experience has been gained, there can be no doubt of rubber becoming a very successful and profitable cultivation in Ceylon. We have already reported how small balls of rubber, gathered from the *Ficus elastica* here, were valued in London at from 2s 8d to 3s 4d per lb. Dr. Trimen has taken home about a pound weight of the rubber got from tapping the trees in the Peradeniya Gardens, and the report upon this produce will be looked for with interest. Meantime, experiments in making excisions in the bark of rubber trees nine months old and upwards are being made every week, and so far with success. A trained cooly can go over 3,000 or 4,000 trees a day, and another on the following day can almost as quickly collect the coagulated strips the rubber oozing out and running down the side of the tree without being lost or injured. The splendid tree on Sembawatte estate referred to in our "Rubber" pamphlet was photographed by Mr. Scowen of Kandy in July 1881 when the tree was 13 months old, and it makes a very pretty picture (for a copy of which we are indebted to Mr. C. Ross Wright). We do not suppose that this tree has been exceptionally treated, and therefore its rapid growth (over 24 feet high by 3 feet in circumference) in two years is only a sample of what the culture ought to be under average circumstances in Ceylon. On Wariapolla, Matale, the progress of the trees is most satisfactory. There can be no doubt that capital could be profitably devoted to the cultivation of rubber trees on a large scale in Ceylon. The product is in great demand ; supplies are not sufficient, and the price at home is steadily on the rise. In connection with our enterprise in "New Products" generally, the thanks of Ceylon planters are due to Mr. A. L. Hutchison for his timely letter to the London *Times*.

MR. T. CHRISTY OF LONDON ON INDIA-RUBBERS.

LONDON, 11th June 1882.

SIR,—I see that a question is asked on page 450 of your weekly edition of the *Ceylon Observer* as to the best manner of getting the indiarubber out of the different rubbers of the "Landolphia" species, and also enquiring when it is likely to come to maturity.

I have studied the habits of the "Landolphias" from the west coast of Africa for about three years, and have taken every information I could gather respecting them, and, after considerable difficulty, obtained one plant of "Landolphia Kirkii" from Kew. This last plant has made its growth, and I can see that its habit is very similar to "Landolphia florida."

Because the Indians obtained the rubber by tapping the trees, that is to say, by cutting holes in

the bark and catching the juice, it is no reason why this course should be followed, when it is necessary to obtain the juice from a different class of tree to the *Ficus elasticas*. If any of your readers who are growing this species of "Landolphia" will take a dead bough or "runner" and cut it through the bark up to the stem, without quite severing the piece, they will find that it is full of gum, and so elastic in quality that, if the woody piece of bark is separated and the gun fibre left, it will spring back to its former position, carrying the bark with it.

This tree throws up every year runners from the roots, and, in my opinion, it is advisable that these should be allowed to mature, and that, when they can be cut down, it will be necessary to find some process for extracting the rubber from the dry bark or from the stems. With this aim Im a trying some experiments, but I need hardly add under what difficulties I labour in this country, only being able to obtain such small pieces. I have written over and over again to the west coast for branches and trees to be sent over to me, but my correspondents say that I have no idea of the expense and trouble of sending into the woods for these faggots and then having to transport them through the surf to the steamers which lie in the roadsteads. There are plenty of substances that will melt the indiarubber, but the object is to find a chemical that can be relied upon, that when treated will return a commercial product in the pure state of "gum elastic."

It must be also noted that, if any experiments are tried, the strength of the spirit should be recorded, for some strengths will melt the resins as well as the rubber

Very little is as yet known respecting the rubbers that come to the London market further than that the merchants classify them as they can turn them to commercial purposes. I have placed before a man, who knew rubber at sight, three samples, all taken from the same tree, the juice or milk having been treated differently. He could hardly believe that the native form which he was accustomed to purchase could be treated so as to yield a clean, clear gum. This proves what may be done by careful collection.
—Yours truly, THOS. CHRISTY.

(By Our City Correspondent.)

Some time back I asked Mr. Heilbut, of Messrs. Heilbut, Symons & Co., the great indiarubber merchants, to obtain some seed for me from their correspondents. At the time Mr. Heilbut gave me little encouragement of being able to do this, but a week back I received the pleasant intelligence that one hundredweight was waiting for me at his office. Upon calling there a glance at the seeds told me they were worthless, but, unwilling to believe this, I took them over to Mr. Christy, who confirmed my impression. There were some five hundredweight in all. I am supplying Mr. Heilbut with the necessary details for proper packing.

I hear that Mr. Chippindall is to go out to Borneo to choose land for the Sub-Company which is being formed in London to take over 500,000 acres or square miles (I am uncertain which) from the parent Company. The Sub-Company has the right to choose its land where it pleases.

Your *Tropical Agriculturist* is not half well enough known in England yet. I handed a copy to a gentleman in Messrs. Lewis & Peat's office yesterday. He takes the greatest interest in cinchona, and has large experience in the article. He had never heard of it, and cannot say too much in favour of it.

Dr. Kirk at the Linnean Society last night exhibited several specimens of indiarubber from the east coast of Africa. He explained the value of the rubber plants exhibited from Kew, the Landolphia florida, L. kirkii, L. petersiana, and the L. watsoniana. He said that owing to merchants sending out for seed in quantities the natives went into the woods, and collected it promiscuously. This will cause planters much disappointment, though it is difficult to see how it is to be avoided. He (Dr. Kirk) values first and foremost the Landol. kirkii, because it hardens very rapidly, next Landol. florida, because it yields a very fine rubber. The other varieties, he states, are of little value. Mr. W. T. Thistleton Dyer exhibited Paramaria glandulifera China. This variety was shown at the Linnean Society in 1881 by Mr. T. Christy, but it has only been recognized owing to some dried specimens being sent home from Cochin-China. The dried stems as sent to Europe certainly exhibit a large per centage of elastic gum, which can be drawn out when the bark is severed. I understand that a specimen of this bark was sent to Ceylon last year. The native name is To-tong. I enclose with this letter another specimen which I send in case you have lost the first, for which I am indebted to Mr. Christy*. It is said that this plant is shipped to China, as the natives use it for smoking. Dr. Kirk does not give much encouragement to cultivators, stating that he considers it doubtful if the growing of indiarubber will be found to pay. But the fact that it can be wound off from the trees of the Landolphia species in a film direct from the tree in a perfectly pure state should prove that machinery can be brought to bear upon its collection. The natives on the east coast destroy not only the stems but also the roots. The shipments of indiarubber from the east coast have risen from £400 in 1873 to £250,000 in 1881. The specimens of Malay and Borneo rubber exhibited from Kew shewed that there was some chance of obtaining supplies in these countries, but owing to the natives employing salt-water in the preparation of the gum it is much depreciated in value.

INDIARUBBER.—It is very desirable that the cultivation of this should be extended as rapidly as possible. Messrs. S. Rucker & Co. assure me that they find it extremely difficult to supply current requirements and prices are rising daily. At Silvertown, I am told by Mr. Silver, they find the utmost difficulty in obtaining the quantity necessary for their extended operations, and, if Ceylon would but come early to the front with anything like a good supply, she would obtain a firm hold of the market.—*London Cor.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

PARIS, June 17th.

Denmark is very justly proud of her reputation for good butter; the mark is appreciated wherever it is known. But, as nothing succeeds like success, Denmark wants to become celebrated for her skim-milk cheese: to achieve this end, she is tormented by American competition, and still more so by her neighbours, the Dutch. Butter farming cannot be financially successful, save that a profitable outlet be found for their milk cheese, in the event of the non-existence of a local demand. The average price of such cheese is about 1½d to 2d per lb.; it reaches double that price in some seasons; Dutch makes realize as much as 4½ lb. The principal outlets for second-milk cheese are warm countries, as soft, rich cheese will not stand a long voyage. In Denmark, there is no uniformity in the preparation of cheese, as in the case of that of butter: less attention is paid to variations of temperature, that which exercises so important an influence on the production of cheese; in-

* The specimen received we took for a piece of renewed cinchona bark.—ED.

deed it may be a question, if, from the industrial point of view, Denmark is up to the mark in the commercial preparation of cheese.

In Germaoy, Milk Societies are the order of the day. They are constituted according to important legal formalities, and severe penalties are imposed on such members as transgress the statutes. The general lines of these Milk Associations are: the members accept unlimited responsibility; each farmer undertakes to supply daily a fixed quantity of milk, over and above that required for home and young stock consumption. Milk from a diseased cow, the mouth-and-foot malady excepted, cannot be received, and the milk from cows after calving must be delivered separately, pending a period of 15 days. If the milk arrive late, the farmer is fined, and, if the cart be not locked containing the tins, the latter must be; the sender and the receiver have duplicate keys; the carter is never entrusted with the key. In winter these cans are covered with straw during the journey; in summer, with damp cloths; the van too must be hung on springs. Some of the societies include 100 members, each furnishing on an average the milk of five cows. As there must be different qualities of milk, how are the farmers paid? They are paid alike; 10 per cent of cream being accepted as a minimum standard of richness. Every mechanical appliance has been tried to test the measurement of the cream in the milk, but without success. Personal and unexpected visits of officials to the farms at milking hours, and taking away them and their samples, are the only practical tests.

But while the percentage of cream in the milk allows of the yield of butter being estimated, there is no test to determine the production of cheese. The richer the milk in butter the less dense the milk, while the contrary is the case for cheese, because the matters rich in cheese are held in dissolution. One of the rules of the Milk Association is that any milk which becomes sour in six hours after delivery will be reduced in price 60 per cent. The milk is paid for every month, never in advance; but the accounts are finally balanced once a year, and dividend declared when the sales for cheese and fatting of pigs shall have been realized. The societies also undertake to supply pure milk to children, and it is becoming the practice to select the neighbourhood of these societies for "nursing stations."

Milk and cheese farming naturally bring in their wake pig-rearing. This is not only the case in France and Switzerland, but notoriously in Denmark. The small pigs in that country are shipped to Hamburg, where they are killed, cured, and exported to England as bacon. The coarser animals are sent to Holland and the Rhenish provinces; indeed some of the hams find their way to France as "Yorkshire" and "Westphalian." The trichine is closely connected with pork. The Academy of Sciences has been discussing the vitality of that parasite. M. Fourmant asserted that a morsel of pork affected with trichine was kept in brine pending fifteen months; it was then left to some mice that died from trichine after eating it. In the uncertainty which reigns, there the popular remedy is the safest, that of well boiling the meat, and which the French ever do, whether it be healthy or diseased.

The Pasteur process of vaccinating cattle continues to make enthusiastic progress. Russia and Italy have sent veterinary surgeons to be initiated into the *modus operandi*, and have had everywhere to note but success. There are two kinds of *charbon* malady: that accompanied by fever and the other by tumors. M. Pasteur confined his discoveries to the first, while Messrs. Arloing, Cornevin, and Thomas have applied vaccination to the second, and with equal success.

The beet crop has taken a considerable extension this year in France, and is destined still farther to extend, when the legislature settles the vexed question of distillation and the sugaring of wines. When wines require body, or to be "cured," beet sugar—never any syrup from grain—is added, which is duly converted into alcohol. Indeed, with beet sugar, a special aroma, a prepared color, and unlimited supply of water, wine can be manufactured at will. The vineyard proprietors allege that, if the law does not check the preparation of artificial wines, the days are counted for classed natural brands.

The reports on the state of the crops cannot be more favorable, and this year promises to be one of plenty. If the yield of hay be light the quality is good, and this is shown in the superior condition of the stock sent either to the shows or to the markets. The season will be a dry one, but taken with all its drawbacks, a tendency to drought is preferable to a constant dripping. In dry weather plants perspire a good deal, and give off their watery vapor to the atmosphere: but in many cases we can correct a little the drawback irrigation where practicable, green manuring, and especially that of the farmyard. For light soils, cow and pig-stye manure is most suitable: it is cool and retains humidity. If there be less consumption, or less waste, during a dry summer of the elements of plant-food, more will be left for the following season.

M. Rodinoff draws attention to the use of calcined earth as a litter. He covers some branches with clay, sets them on fire and the earth is baked; it must then be kept under a shed to prevent absorption of humidity. In the calcined form, the absorbent power of clay is naturally augmented: in that state it is better fitted also to fix gases. It is more suitable for a sheep than a cattle shed, and, when employed in the latter case, a slight sprinkling of straw will be an improvement. The best litter is that which will absorb most urine, &c., in this sense, following:—Boussingault, bean, buck-wheat and pulse straws are first, as they absorb 3 times their weight of liquid: wheaten straw, but twice its weight, and dried earth, but one-half. The latter then is only four times inferior to wheaten straw.

There is nothing special to record respecting the phylloxera: the enemy is being bravely fought everywhere, and the means, sulphuret of carbon, &c., autumnal irrigations, and last, not least, strong manurings.

M. Joulie gives some very sensible explanations respecting the laying of grain. It is popularly, but erroneously, believed that the laying of wheat, &c., is due to a deficiency of silica in the stem. Analysis however, has shown that this is not so, there being no perceptible difference between the laid and the stalwart stem. Corn lies, because the stem or the foot is weak, and this weakness is the consequence of moist, warm weather, and the absence of sunlight; the latter prevents the elaboration of carbonic acid to enable the plant to form cellulose, or sinew, and which imports solidity. The stem becomes not ligneous but herbaceous and etiolated; it breaks at the base, from want of regular nutrition; it has "rickets;" it is unable to support the upper part and ears; consequently the crop is laid and destroyed. This is not the same with grain laid from wind and heavy rain.

Wax Palm Seed.—We are glad to be able to report that this seed sent here from South America and which has been neglected so long, because it was nearly all supposed to have lost its germinating power, has been most successfully germinated at Hultsdorf Mills. The seed experimented with there is germinating steadily and it is very satisfactory to know that this useful tree will now be introduced into the island. Every one interested in land should have a few trees of this new product, if for seed alone. By and bye the trees will be very valuable. Germinated seed will shortly be available.

JAMAICA: A NEW INDUSTRY FOR CEYLON.—The supplies of the lace bark tree—*Lagetto lintearia*—are stated to be falling short. It is the inner bark of this tree which, when macerated in water, yields a most delicate lace-looking material, which for several centuries has been largely used for ladies' articles of dress. A former Governor presented Charles II. with a cravat, frills, and ruffles made of it, and the Woman's Self-help Society has of late derived much remunerative employment in the preparation of similar articles; the threatened diminished supply is therefore regarded seriously.—*Colonies and India.*

THE "TROPICAL AGRICULTURIST."—We have had lent us by a friend a number of the *Tropical Agriculturist*, published in Colombo, Ceylon. Its perusal enables us to state that we view it as a serial which will be found most interesting to every planter, as the large amount of information contained in its varied and able articles cannot fail to prove of value to them. Cocoa, tea, coffee, cinchona, sugar, rice, palms, and other products are dealt with. The contibutions are from scientists of acknowledged repute, whilst the statistics which it furnishes are highly important. The articles on cinchona cultivation and production are exhaustive and replete with information, which, with the extended cultivation (by private individuals) of this plant now going on in Jamaica, must be perused with great attention. The *Tropical Agriculturist* we must not omit to say is published by Messrs. A. M. and Ferguson, *Ceylon Observer* Office.—*Trinidad Chronicle.*

NEW INDIARUBBER PLANT.—Some months ago the Civil Surgeon of Kurrachee, Dr. Adey, had his attention drawn to certain Indian plants capable of producing Indiarubber. Of those he experimented upon, he found that the *Cryptostegia grandiflora* was the only plant which produced juice in a sufficient quantity to make it worth while to use as an indiarubber-producing plant. The results of his experiments led to a discussion in which the Superintendents of the Botanical Gardens at Guiesh Khind, Saharunpore, and Calcutta took part. The Government has now come to the conclusion that a new and more extended trial of the plant is necessary, and that Mr. Birdwood should co-operate in the experiment. With this view the Commissioner in Sind has placed a sum of R100 at Mr. Birdwood's disposal to enable him to conduct the experiments on a proper scale. It is understood that a sample of the rubber obtained from the *Cryptostegia gradiflora* will be sent to England to test its quality and to ascertain its market value.—*Indian Daily News.*

CINCHONA MACHINES.—Badulla is to the front again. And yet another cinchona machine. You readers may cry out, "Won't they stop," yet this machine is simplicity and cheapness combined, and capable of turning out 400 lb. of wet bark a day, with one cooly to feed the machine, two to bring the twigs, and one to dress the bark. It is the invention of Mr. Fraser of Messrs. Walker & Greig, Badulla, and be it noted that this enterprizing firm, or rather a member of it, has brought the most useful machines. This barker is extremely portable, the weight being 30 lb. The cost is not much, R15, which is a point not to be lost sight of in these hard-up days. The facility with which the machine works is astonishing, and any odiyan will be able to manage it, and it is destined to supercede the alavanga and bottle dodge. The patent has not been obtained, and so I refrain from giving particulars of the instrument. From all that is known de Caen's it is an awkward machine. The McInnes and Mackenzie machine will do well to bark old trees, and "Fraser's own" will strip twig bark, as well as up to the thickness of the arm of a man. It strips clean without *punishing* the bark. I was also courteously shown a cinchona press which the same firm is bringing out. It will press within the compass of a three bushel bag 60 lb of bark, that is double the quantity at present obtained by cooly labour. When this machine is more generally known, planters will find out that labour and money will be greatly saved.—*Cor.*

INDIAN TEA.—Auctions, comprising 11,000 packages, have been held, and nearly the whole has been taken by the trade without further concession in value, except in the case of teas wanting quality, which are neglected and cheaper. Some of the finer lines have attracted more attention from the exceptional value offered to buyers at present rates, and show a tendency to recover. From Messrs. W. J. and H. Thompson's circular:—"On June 6th the closing sale of the Assam Company's crop was effected at comparatively full rates, and on the same day the first arrival of the new crop was sold—viz., 100 chests from the Land Mortgage Bank's Moonda Kotee estate, Darjeeling which were of superior quality, and realized an average of 1s 6¾d per lb, compared with 1s 0¾d. for the corresponding invoice last season.—*Overland Mail.*

THE CONSUMPTION OF TEA AND COFFEE.—Mr. H. Barter writes, *apropos* of Mr. Gladstone's "perplexity," at the fact that the consumption of tea steadily increases while that of coffee steadily decreases:—The "perplexity" is easily solved. It is because of the great increase in the consumption of tea that that of coffee decreases, or, what is more correct to say, remains steady. The facts and figures about tea are very interesting. In 1841 the consumption of tea in this country was 41,459,000 lb.; in 1851 it was 58,500,000 lb.; up to this date the duty on it was 2s 2½d per lb. In 1853 Mr. Gladstone began his grand campaign against the tariffs. Tea was one of the first articles attacked, and the duty was reduced to 1s 10d. per lb; in 1854 it stood at 1s 6d; in 1855-6 it was raised to 1s 9d; from 1857 to 1862 it stood at 1s 5d; in 1863-4 at 1s; and in 1865 it was reduced to 6d per lb., where it now stands. The rapid growth in the consumption during these years has been perfectly marvellous. So great has it been that last year, 1881, it reached the enormous total of 160 millions of pounds, as against 58 millions in 1851, when the duty stood at 2s 2½d. The revenue derived from it at 6d per lb. duty reached a total of over four millions sterling, against a revenue of about six millions in 1851, so that this enormous relief to the people—to say nothing of the indirect advantages such as stimulus to trade—has been secured without very much loss to the revenue, and has largely increased the comfort and happiness of the people. The consumption of coffee has remained steady during the period to which I have referred, being about 32,000,000 to 35,000,000 lb. a year. The fact is that the English people, and especially the poorer classes, are a tea-drinking rather than a coffee-drinking people.—*Home and Colonial Mail.*

INDIAN TEA.—The following details may interest our readers:—Indian tea, till within the last few years has been used in England almost entirely for improving the liquor of low-priced China tea. From the beginning, Ireland has been the great stronghold, and the prices paid by grocers in quite small places in the north of Ireland for the finest grades would astonish Sydney buyers. In Belfast and Londonderry, 3s 6d and 4s per lb. *in bond* is not an extraordinary price for a grocer to pay. Of course his customers would not give him a profit on these prices, nor would they find the tea palatable if they did, but by judicious blending he has found a way to make them most profitable and exceedingly palatable. The poorest and smallest grocer in Ireland now says, "I like your broken *Assam*, they give so much liquor." Originally all Indian tea was called "Assam," no matter what district it came from, so much so that it was not an unheard-of thing to be asked for "Java Assam" when the grocer wanted to reduce the price of his mixture, and still sell pure Assam tea. At the leading clubs in London, where there are numbers of retired Indian officers, and the Army and the Navy Co operative stores, the tea consumed is almost pure Kangra Valley tea. In Scotland the larger leaf teas or souchongs are taken, and the grocer there goes to the trouble of cutting the leaf down in a mill, in order, no doubt, that his customers may get as much weight as possible into a teaspoon, many of these teas being improved by being triturated.—*Tea News.*

PACHOULI AND THE DISTILLATION OF ESSENTIAL OILS: NEW INDUSTRIES.

4, Guildhall Chambers, 33, Basinghall St, London E.C.,
9th June 1882.

DEAR SIR,—We can reply to one query made by "W. T. McK." in his letter upon pachouli under date 21st March in your *Tropical Agriculturist*. He wishes to know how it is obtained. In reply we will give particulars of a small still which has lately been brought out in London, the price for which brings it within reach of all, and should make the extraction of perfumes an interesting occupation for ladies as well as a profitable pursuit possibly in your island, favoured with such luxuriant growth of vegetation. The price of this still is 45s. Many a flower is wasting its sweetness in the desert air, but the gardens of Damascus and nearer home, the neighbourhood of Mitcham in Surrey, yield most profitable returns to the cultivators. By the aid of the still the essential oil which is the cause of scent in flowers is obtained. There exists a considerable difference between the oils producing perfumes and those which are used in lamps, &c. The latter are termed *fixed* oils, whilst the former, from being easily evaporated, are termed *volatile* oils. This difference will be readily understood by trying the following experiment. Drop a little otto of roses and some almond oil on the two opposite corners of a piece of blotting-paper, and hold each over the flame of a candle. The otto of roses if pure will evaporate entirely without leaving the least stain, whilst the almond oil will not leave the paper until it is completely burned. From this may be marked the difference between oil produced from flowers and from fruit. The object of the still is to separate the volatile oil from the grosser or solid parts with which it is associated. For this purpose heat is applied to convert the oil first into a state of vapour, and subsequently this is condensed and becomes a liquid. Some flowers yield their essential oil readily; others part with it more slowly. The distillation of brandy, rum, gin, then wine, and lastly ale, can be tried first, as these contain successively less spirit, and so prepare the way to the more delicate and less producing process of the distillation of flowers. When a tolerable amount of success has been arrived at, then the distillation of a spirituous extract of the essential oil of flowers may be attempted, and so by each step a readiness and ease in the use of the still will be acquired.

We are making enquiries as to the market value of the produce, and other particulars which may be of service.—Yours faithfully. HUTCHISON & Co.

COVERING CINCHONA TREES:—EXPERIENCE RELATED AND INFORMATION WANTED.

DEAR SIR,—I purposed writing you today on the subject of covering for shaved cinchona trees in the hope of eliciting from you, or some of your correspondents, a few wrinkles which might help me in my perplexity.

I now find from your issue of the 26th inst. there are others, as well as myself, in want of information, and, as I have tried one or two of the substances mentioned in their letters, I shall give my experience of them, and trust others will enlighten, as to what substances they have found most satisfactory.

Plantain leaves and pith I used last year, and these seemed very suitable until showery weather began, when they soon decayed, became infested with insects, and had to be removed sharp.

Clay and cowdung, which, I was informed, were the correct cards, were also tried, and proved a complete failure.

Old sacks were a great success, but they too had to be removed when the wet weather set in. Sacks are expensive though, when manuring is not the order of the day.

I subjected four trees to Karslake's dodge. The sun soon shrivelled up the strip of bark left on the trees which made it useless as a covering. One tree renewed well, one middling, one badly, and one not at all.

This year I began with straw mats on a few trees. The first showery weather mildewed them, and the insects soon appeared in shoals, so they had to be discarded. Their cost too would prohibit their use when grass is plentiful.

Mana and guinea grass were also tried, and there can be no doubt the former is much superior to the latter, as it does not stick to the tree so closely nor rot so soon, but I have just removed it too, as it undoubtedly damages the bark during wet weather also. Bar the clay and cowdung I have no doubt any of these substances is quite suitable for covering during dry weather, and probably sacks or mana grass would answer all the year round in a comparatively dry district, but here we get long spells of moist weather during which everything gets saturated and rots sooner or later and must then be removed.

What I should feel obliged to learn is: do shaved trees require any covering in a cloudy climate, and, if so, what substance has been found most suitable during wet weather?

I have seen shaved trees renew their bark in dry and wet weather without any covering which leaves nothing to be desired as far as appearance goes, but the question seems to be what about the quality?—Yours truly, SCEPTIC.

P.S.—Last year my trees were only partly stripped; this year shaved. S.

INSECTS IN RUBBER SEEDS.

DEAR SIR,—Under separate cover, by same post, I send you eight Mozambique pink rubber seeds (Landolphia Kirkii), infested with small white worms.

These worms must have come with the seeds, as the other kinds of rubber seeds, in the same bed, are unaffected, and have vegetated very satisfactorily; while, of the Landolphia Kirkii, not a seed has germinated, although they have had every attention.

Can you, or any of your correspondents, recommend a recipe that would destroy the worms without injuring the seeds? PLANTER.

[In this particular case, killing the worms which have already killed the seeds would be of very little use. The great point is that care be exercised in collecting and packing the seeds. We should think a slight fumigation with sulphur might destroy all insects and their eggs without destroying the vitality of seeds. But gardeners and others in the habit of collecting and despatching seeds, must have long ago fixed on the best agent for destroying the life germs of insects without injuring the germinating powers of seeds.—ED.]

THE CORK TREE:—A NEW INDUSTRY.

Badulla, 26th June.

DEAR SIR,—Enclosed is a cutting taken from the *Engineer* of 2nd June regarding the importation of cork by England and its cultivation in Algeria.

Can you give any information as to whether the cork oak has been reared in Ceylon?—Yours truly,

B. B.

England imports some 10,000 tons of cork per annum, and the quantity is yearly increasing, notwithstanding the introduction of many stoppers and substitutes for corks, such as plugs of wood, whose fibres have been specially softened for the purpose, indiarubber, and other materials. The French Government are giving special encouragement to the plantation of the cork-oak in Algeria, and the same thing will, no doubt, be done in Tunis; but, the *Colonies*

says, the tree will grow equally well in India, Central America, the West Indies, many parts of Africa and Australia, and in the South Sea Islands: the planters in our possessions there might lay the foundation of a profitable industry by introducing some of these trees and starting their systematic cultivation. The tree, besides being a most valuable one and easily cultivated, is of magnificent growth, and would form an ornament in any landscape.

We take the following from the *Planters' Gazette*:—

There can be no reason, however, why the cork tree should not be cultivated in some of the British colonies, so that this country may be rendered independent of foreign supply, since England alone imports about 10,000 tons of cork per annum, and the amount is yearly increasing. The requirements of the tree are an altitude of from 1,600 to 3,200 feet, a climate having a uniformly high temperature whose mean annual average is not less than 55° Fah. and a southerly slope on a granitic, silicious or slaty soil, where a free circulation of air and exposure to light is admitted. Profuse nightly dews and abundant moisture with efficient drainage favour the development of fine cork, which, under these circumstances, becomes more elastic and less porous. The tree will not flourish on calcareous soils, nor beyond a latitude of 45° N. Wherever these conditions are complied with the cork tree can be successfully grown; and there are many places in India, Central America, the West Indies, Africa, the South Sea Islands and Australia, where the foundation of a profitable industry might be laid by introducing the cork tree. In the last mentioned country there exists a native cork tree *Quercus occidentalis*, which is hardier than *Quercus Suber*, and which according to Dr. Mueller, yields a very good cork bark.

It should be stated, however, that the cork oak does not arrived at maturity until fifteen years old, and can then be cut with profit only every six or eight years, so that it would probably pay best when grown as an adjunct to other plantations. Indeed, it might do good service in preventing the spread of fungi, by forming a separating line between different coffee plantations, since it is unquestionably the case that the coffee disease extends more rapidly on account of the close proximity of a number of trees of the same species.

In France, about 110 to 120 trees to 2½ acres is thought to be sufficient, and each tree is calculated to produce about 181 lb. of cork. The best cork comes from Sardinia and Tuscany, and seeds of these trees are therefore preferable for cultivation Large and sweet acorns develop into the most regular trees, and produce the finest cork, while trees grown from bitter and small acorns yield an inferior bark.

The inner bark of the tree yields about 12 per cent. of tannin, and an extract is prepared from it which is more easily obtained than that from English oak bark. As it yields a dark leather, and very little "bloom," it is generally mixed by tanners with valonia, or English oak bark. In Italy it is largely used in tanning sole leather; Marseilles also annually imports large quantities, and Ireland at one time consumed 8,000 to 10,000 tons of it. But this extract can only be obtained where the trees grow freely, or from those which have to be thinned out, since its collection involves the destruction of the tree, the tannin being contained in the bast layer or inner bark.

[Has the cork tree ever been tried in Ceylon, beyond the precincts of the Botanic Gardens?—ED.]

THE MAHWA TREE.

30th June 1882.

DEAR SIR,—Referring to the article on the Mahwa in your issue of the 27th, there are several kinds in Ceylon answering thereto, all known as migas, of which Tehni is the best, and is cultivated for its oil which the Sinhalese mix with their rice. The estate Tamils call it illapu and eat the flowers after being dried. Neither the Sinhalese nor Tamils in Ceylon know anything of the arrack or whisky that can be distilled therefrom. The Sinhalese value the tree on account of its timber as well as for the oil and burn the gedi after being dried as a light. The migas may be now seen in flower on the banks of the Mahawaliganga, below Katnmittala, in such abundance that they turn the water of all the oyas and small streams quite black in their decomposition, and the nauseous effluvia will indicate their presence long ere the eye alights on the white flower. This scent is supposed by the Sinhalese to give fever, and I have seen Sinhalese vomit frightfully after eating fish (although boiled or cooked) caught whilst the flower of this tree was falling. NEMO.

[The Mahwa tree (Bassia latifolia) is not indigenous to Ceylon: the tree to which Moon gave this name with the Sinhalese one of Kini-hæmbiliya is no doubt the same as the one described by Dr. Thwaites as Isonandra grandis, in *En.* p. 176, from which an oil is extracted and used like that from the Tel-mee-gaha (Bassia longifolia) which is the Illupei of the Tamils: 4 species of Dasyalus, 1 do. Dichopsis, and 7 species of Isonandra, given by Dr. Thwaites are all now included as mere sections of Bassia, so that we have 13 species of Bassia in Ceylon, but only two of them resemble the Mahwa of India, and it is questionable if they are worth cultivating for their flowers, as food at any rate. The Bassia (Isonandra) grandis is well-known in the Central Province as a timber tree under the Sinhalese name Meeria or Meehiriya, whilst the same tree is known in the Western Province as Heen-kiri-heriya.—W. F.]

COVERING CINCHONA TREES.

No. I.

1st July 1882.

DEAR SIR,—In your issue of 26th ult., in answer to "Dikoya Planter," I would suggest, on the subject of covering cinchona trees after barking, that a collodion of indiarubber, guttapercha, or some vegetable gummy exudation, might be used. Should this, however, be rejected on account of its impermeability to gases, *i. e.* preventing osmosis, I think gum acacia and chalk, or some species of gum and plaister of Paris, would, perhaps, be preferable, on account of being porous. In this case *external support might be rendered*, if necessary, by means of *strips* of a very thin, *unbleached calico*, thinner in texture and cheaper than are surgical bandages, or *narrow strips of gauze*—in fact any cheap texture to answer the purpose. It is quite possible in time that *not only* inoculation *to increase the percentage of sulphate of quinine, but also*, after the first and subsequent barkings, *the rapid formation of fresh bark* by the application of some stimulant (liquid or solid); just as in "granulation" is illustrated this point, in the formation of new tissue in "animalia."

Planters will do well (not to confine this to experts only, but to extend the number of close observers) to study "Vegetable Histology," *e. g.* cinchona barks, not only in minute structure, but formation and requirements in birth, growth, development, decline and death; and so progressing in knowledge, may eventually come to the consideration, understanding and explanation of the pathology of cinchonas: but far higher education and keen appreciation of symptoms —*i e.* slight alteration in the daily condition and wants of plants—is necessary to effectively carry out these suggestions than take it as a rule exists at present, though of course the scientific cultivation of cinchonas is more or less in its infancy.

As to a method of accelerating the formation of new bark, I would suggest that "skin-grafting" *e. g.* (on the surface of wounds, where there is extensive destruction, or removal of the external covering or skin—*vide* Bryant's "Surgery"), illustrates in animal life one of the stimulating processes. I now suggest as being applicable to vegetable life, in assisting the formation of new bark both as to time and improvement as to quality (in the case of the latter) under study and care *at the proper moment.*

This process of "grafting" *bark*, not in the general acceptation of the word *grafting*, as applied in horticulture, applying in this case to *bark only*, brings us to consider how closely this process of "bark-grafting" *combines* and *resembles* vaccination and inoculation. Hence I suggest that, instead of grafting a tree with its own bark, or skin, it be grafted as in the case of a fine, large, straight and healthy succirubra with the very finest, *healthiest* and most suitable ledgeriana bark, or, if not procurable, with at any rate one of the more valuable cinchona barks, suitable of course to the altitude, soil, climate, etc.

These suggestions are original, and theoretical only. However I hope they will lead practically to further consideration and result.—Believe me, your obedient servant, S. STILLINGFLEET TOWLES.

P. S.—Budding roses, as done at home, is an example of grafting bark.

No. II.

DEAR SIR,—If your correspondent "Sceptic," in your issue of the 1st inst., will use ferns as a covering for his shaved cinchona trees. he will find the ferns sufficiently open to keep the bark cool and so prevent injury from damp; and they will also prove a thorough protection to the bark from the rays of the sun. S. A.

CINNAMON.

3rd July 1882.

SIR,—I am pleased to find that the agitation set on foot by "Cinnamon" in the local "Times" and taken up by me in your columns has been productive of some good. Though there are scores of men in the country who will be benefited directly by the suppression of chips, yet such is the apathy amongst us natives, that no one interested himself in the subject, till "Cinnamon" with commendable zeal distributed copies of his letter to many of the principal native landholders, and through the medium of private letters to the most influential amongst them managed to set on foot the NATIVE AGRICULTURAL ASSOCIATION. Long years of usefulness I wish it most heartily.

This is one outcome of the agitation. Another is that the subject has attracted the attention of the brokers in London, as I find by the letter of your London correspondent. It is idle for your correspondent to say that the withdrawal of chips will not influence the price of quilled cinnamon. If he refers to the export of chips, the quantity sent from Ceylon for the last two years will appal him. I am sorry I have not your "Directory" at hand to give the exact figures (please supply the omission*); but, if the withdrawal of this immense quantity does not give us a better price for our quilled cinnamon, nothing will. We in Ceylon have not the slightest fear of China supplying what we withdraw from the market. Confectioners with an established reputation will be slow to use the next to worthless cassia bark for flavoring purposes, in the place of cinnamon. Cinnamon, whether quilled or in chips, must I suppose, be ground to powder when used for flavoring confectionery. No wonder then that chips find so much favor amongst small confectioners, as the quills we bestow so much care in preparing, when ground to powder, cannot be distinguished from powdered chips, except by an expert, who will be able to detect a milder flavor in the former. If chips be withdrawn, and cinnamon be still in demand by confectioners, it is reasonable to suppose they will go in for quilled cinnamon, and with increased demand prices will rise. When the prices of cinnamon went up about a twelvemonth back, I remember reading in the commercial letter of either the *Observer* or the "Times" that the keeping up of the prices was practically in the hands of the growers, by keeping back the immense quantity of chips then flooding the market. For the London brokers to now tell us what is opposed to all commonsense is foolish.

As for the arguments against monthly sales, I need not take the trouble to refute them, as your correspondent simply repeats what the brokers told us before. We were not satisfied with the soundness of their arguments, neither are we now. Self-interest makes them still adhere to antiquated and out-of-date quarterly sales.

I trust, now that the Association has been formed, some member will ere long bring forward a motion by which all members will bind themselves to discontinue scraping chips on their estates—even for a couple of years. If the withdrawal of chips does not favorably affect the price of quilled cinnamon, then we can all resume scraping. Again wishing the Ceylon Agricultural Association long years of usefulness, I subscribe myself, PLANTER.

* The export of cinnamon chips in the last three seasons was 118,518 lb., 474,484 lb., and 321,772 lb. respectively.—ED.

RIVALRY IN SILK AND TEA: SILKWORMS IN CEYLON.

Dimbula, 4th July 1882.

DEAR SIR,—There are one or two rather misleading statements in the article under this heading which is quoted from the *China Mail* in your paper of the 1st inst.

First we are told that "the conditions which form the plant are prejudicial to the insect, and *vice versa*." Then, in warm regions the silkworm "obtains maturity in less than half the period in colder localities. . . . This reduces the liability of loss from disease." &c. &c.

As regards the first statement, can any proposition be more absurd? The mulberry being the natural food-plant of the silkworm, are we to infer that there has been a grave error made in the laws of Providence? The mulberry tree may "thrive better in cold climates," but this is no proof that it is better adapted as food for the worm. Most trees may be improved by "high cultivation," but pruning and manuring the mulberry at all heavily renders the leaf unsuitable.

As regards the second statement, experience here supports the views of Capt. Hutton, published so long ago as 1859:—"A temperate climate is by far the most suitable for it; beyond 80° Fhr. I confess I should look for nothing but debility and sickness. . . . Nearly all competent observers have remarked that the longer the worm takes to come to maturity the better will be the cocoon."

It is true, as the *China Mail* remarks, that cards of eggs sent from China and Japan have reproduced successfully; a large proportion of the grain hatched. One gentleman wrote me that he had millions of worms, but I have not heard that they were a success. Hatchers of eggs from either country continued to hatch out day after day for six months or longer, and, if this was not a sign of debility in the parent stock, it was the result of indolence or fraud on the part of the exporter. I pointed out in a former letter that it was most important in rearing silkworms to have the utmost regularity in every stage from the time the young worm leaves the egg until the spinning of the cocoons. In any properly-managed establishment the moths would not be allowed to lay their eggs promiscuously for months together, but each day's eggs would be kept separate.

I do not think there will be any occasion for Ceylon to procure more "grain" from China or Japan, as we have eggs now of a far healthier standard than "the heathen Chinee" is likely to offer for exportation.

Sericulturists will do well to bear in mind that the worms should not be fed on leaves from trees under three years old, at least, as immature leaf increases the debility of the worm, and, of course, spoils the quality of the silk.—Yours faithfully, B.

CINCHONA: PRICES HERE AND AT HOME.

SIR,—If your facetious correspondent "Merchant" would refer to the *Ceylon Observer* of last Monday, July 3rd, he will therein see a confirmation of my statement respecting the value of Ceylon bark and the absurdly small prices obtained locally.

Rucker & Bencraft's Price Current of June 8th quotes Howard's quinine at 9s, quinidine 5s, cinchonidine 2s 6d, and cinchonine 1s 3d for new bark, giving by a *reliable* analysis 1·22 of quinine, fetched 2s 2d per lb, equivalent in rupees currency R1·26 whereas locally 60 cents could only have been obtained. —Yours faithfully, LATE BROKER.

ROOFING FELT AS A COVERING FOR CINCHONA.

SIR,—A good covering for cinchona trees still seems to be a desideratum. If the following idea is worth a thought, use it, or you have a useful basket. The only doubt I have about it is the cost or will it pay—at any rate I think it would for valuable trees. What do you say to roofing felt? It is cheap, and I dare say a much cheaper article could be made, suitable for the purpose in question. It could be cut to the exact size required, and would last for years, and be very easily applied, just tied round in two or three places with coir string. When the tree was sufficiently covered, it could be removed in a minute, and used again or stored away till wanted. It would not harbour insects; any ventilation thought necessary could easily be provided for by resting it on a stone or two or forked stick at the bottom, where air could enter, and a few holes could be made with a gun-wad punch.—Yours, S.B.

P. S.—If the the cheapest stuff of the kind now made is too dear, which is likely (though very cheap for roofing), I feel sure very cheap stuff could be made, that would do well for covering cinchonas.

NEW INSECTS INJURIOUS TO AGRICULTURE.—Mr. C. V. Riley remarks that almost every year the appearance of some insect or insects injurious to agriculture, but previously unknown in an injurious capacity, has to be recorded. These new destrucive species may either be (1) recently introduced species from some foreign country; (2) native species hitherto unobserved or unrecorded and new in the sense of not being described; or (3 native species well known to entomologists, but no previously recorded as injurious. The author argue that, in the last two categories, more particularly, w frequently have to deal with newly-acquired habits and, in the second category, with newly acquired char acters that in many cases systematists would con sider of specific value. In short, he believes that certain individuals of a species which has hitherto fed in obscurity on some wild plant may take to feeding on a cultivated plant, and with the change of habit undergo in the course of a few years a sufficient change of character to be counted a new species. Increasing and spreading at the rapid rate which the prolificacy of most insects permits, the species finally becomes a pest, and necessarily attracts attention. The presumption is that it could not at any previous time have done similar injury without attracting similar attention—in fact that the habit is newly acquired. The author reasons that just as variation in plant life is often sudden, as in the "sport," and that new characters which may be perpetuated are thus created, so in insects there are comparatively sudden changes which under favouring conditions are perpetuated. In this way characters which most systematists would consider as specific originate within periods that are very brief compared to those which evolutionists believe to be necessary for the differentiation of specific forms among the higher animals.—*Gardeners' Chronicle.*

CALISAYA BARK.—At a meeting of the Pharmaceutical Society on March 1st, Mr. Umney said that Mr. Gerrard had alluded to cinchona bark, and imagined that he could standardize it. He would assure Mr. Gerrard that great difficulties presented themselves, inasmuch as at the present time he believep it would be impossible to obtain in the London market a single hundredweight of flat calisaya bark which would come up to the Pharmacopœia standard. The requirement was, as they knew, 2 per cent of quinia. The flat calisaya barks, however, now present, would not probably contain more than 0·8 per cent of that alkaloid.—*Pharmaceutical Journal.*

TEA CULTURE in South Carolina bids fair to become an important industry. A reporter of the Georgetown *Enquirer* says:—"The tea plants of Friendfield Plantation, the residence of Dr. Forter's family, have been submitted for inspection to a leading importing house in Baltimore, and the tea produced therefrom is pronounced by them to be equal, if not superior, in pungency, and in strength and richness of flavour, to the finest imported article. There are now in Friendfield 1,642 tea plants, all exhibiting a splendid and vigorous development. Some of these plants, which have been allowed to grow without pruning, are six feet high with a circumference of ten and twelve feet."—*Pioneer.*

INJURIOUS INSECTS AND FARM CROPS.—Mr. H. M. Jenkios, the Secretary of the Royal Agricultural Society, has just issued a circular to members and others in which he states that the seeds and plant diseases committee would be much obliged if any person would forward to Miss E. A. Ormerod, of Dunster-lodge, Isleworth, the consulting entomologist of the Society, any information respecting the injuries caused by wireworms to various crops that they might be able to give, also as to any remedial that has been found beneficial. It is intended to collect and publish the results of the observations and practical experience of agriculturists in all parts of the kingdom concerning the attacks of wireworms, which have been unusually disastrous this season, in the same manner as has been done by Miss Ormerod during the past year with regard to turnip flea, and all persons are earnestly requested to give their assistance in this work. Information is especially desired upon the following points:—(1.) The extent of the injury and the probable money loss caused by such attacks. (2.) Methods of treating pastures or clover leys before they are broken up and the results of the application of dressings and of rolling, bush harrowing, and other means which have been found serviceable to prevent the click beetles from laying their eggs and to destroy the wireworms. (3) The effects of any special methods of cultivation as well as of the treatment of land whose crops have been affected—such as rolling, treading by sheep, or other means. (4.) The results of the application of artificial manures in encouraging the rapid growth of the plants affected, the special effect of rape cake, and of caustic manures put on to directly check the wireworms. (5.) As to whether land is more subject to wireworms attacks after certain crops (for instance "seeds"), and the special precautions taken in such cases; also whether crops, such as mustard and peas, act as preventives of attack. (6.) Upon any other points in connexion with wireworm attacks that may have been noted. The circular contains a very good illustration of the click beetle and wireworm, to enable farmers and others to identify the pest.—*London Times.* [Query as to the effect of caustic manures on cockchafer grubs; caustic lime, for instance? As for plants to attract insects from the coffee roots, their cultivation would mean weedy estates, and yet we believe a crop of mustard was tried in one instance in Maskeliya with some degree of success. —ED.]

TO REMOVE WORMS FROM LAWNS AND POTS.—Place a peck of quicklime in thirty gallons of water, stir well up, and allow it to stand for a few days until it is quite clear; then water the lawn thoroughl with the clear lime water. The worms will come to the surface when they may be swept up and cleared away. This is an old and useful mode of eradication.—*Indian Agriculturist.* [It might be efficacious in bringing grubs to the surface on coffee estates?—ED.

TO WATERPROOF CALICO.—A cheap and easy mode of rendering calico waterproof, so as to make it applicable as a temporary substitute for glass as a covering to frames, is by the following process:—Take pale linseed oil 3 pints, sugar of lead 1 oz., and white rosin 4 oz.; grind the sugar of lead with a little of the oil, then add the rest and the rosin. Stir the whole well together in a large iron pot over a gentle fire. Tack the calico loosely on the frame, and apply the mixture while hot with a large brush.—*Gardener's Chronicle.*

LIQUID GRAFTING WAX.—This is a very useful application, and is, perhaps, the most convenient for the purpose of all the mastics used for covering wounds and grafting. It is of the consistency of varnish, and is applied very thinly with a brush. Care must be taken got to lay it on thickly, for the surface hardens so rapidly that the alcohol is prevented from evaporating. VII.—Rosin 1lb., beef tallow 1oz, spirits of turpentine 1 tablespoonful, alcohol (95 per cent.) 6oz. Melt the rosin over a slow fire; when melted, take it off and add the beef tallow, stirring it constantly; let it cool down somewhat, mix the spirits of turpentine little by little with it, and at last the alcohol in the same way. Should the alcohol be added while the mass is too hot, much will be lost by rapid evaporation; if, on the contrary, it is too cool, it will form a viscid lump, and must be slightly heated again. Stirring briskly is indispensable to mix the ingredients thoroughly. In well-corked bottles it keeps for years. If course of time it becomes too thick, the addition of some alcohol will make it liquid again. For this purpose it must always be warmed. It is a good plan to put the bottle containing it in boiling or hot water to accomplish this.—*Ibid.*

TEA.—THE REPORT of the Doom Dooma Tea Company for 1881 must be a comforting document to the shareholders. It shews a dividend earned and declared of 10¼ per cent. To those who purchased their shares at par, this is a snug income, and even to those who buy at the present enhanced rate of the shares (136), it represents a return at the rate of 7½ per cent. The report gives evidence of good management in the factory as well as careful control in the office, and given these *desiderata*, it were strange this Company's career should not be a prosperous one. The outturn was 622,565 lb., being at the rate of 425 lb. per acre of plants in full bearing. The cost of this tea in London, including all Calcutta and London sale charges, and allowing for exchange, was one shilling and one-eighth of a penny per lb., equal to 8 as. 1 pie. This must be considered particularly good. The estimate for the present year provides for 676,000 lb., at a cost on the factory of 4·4 annas per lb. Allowing for exchange, last year's cost 6 annas per lb., so that the present year promises well. A heavy item, apparently, is the sum of £581-13 9 for directors' fees, but, as this is made up of five per cent. on the sum available for dividend, it is clearly well spent. The system of paying such fees by a fixed payment per meeting is wrong in principle, while that adopted by this Company is financially sound. Perhaps the most satisfactory item in the accounts is that of £870, commission to European establishment. This item increases the salaries of these gentlemen by no less than 29·63 per cent. This is the true way to make people take an interest in their work, by making interest and duty run on parallel lines.—*Indigo Planters' Gazette.*

GIGANTIC BAMBOO.—Messrs. Skeen & Co. remind us that the photograph from which an engraving was made for the *Gardener's Chronicle* of the gigantic bamboo at Peradeniya Gardens, was taken by them and was accompanied by Dr. Trimen's graphic description. Messrs. Skeen's indeed is a more complete picture than Mr. Scowen's, taking in the whole group and displaying a wealth of vegetation and a glimpse of river scenery seldom equalled even in tropical representations.

GRAFTING WAX.—Grafting wax is very much used on the Continent for protecting newly-made grafts instead of the clay and horse droppings formed into a plaster, such as is used in this country. It is also of great service in covering fresh wounds in trees, made either by accident or design, and is a much more cleanly substance, as well as a more neat application, than the ordinary grafting clay. I have here furnished various formulæ for making the grafting wax or mastic, and, as I have used them all at various times, they may be relied upon to answer the purpose for which they are intended. The first five require to be melted in an earthen pot over a fire, and to be applied warm, but not so hot as to injure the tissue of the bark with which it may come into contact. I.—Rosin 1 part, yellow wax 1 part. II.—Black pitch 5 parts, rosin 1 part, yellow wax, 2 parts. III.—Burgundy pitch 1lb, black pitch 4oz., yellow wax 2oz., rosin 2oz., mutton suet 2 drams. IV.—Yellow wax 2 parts, suet 1 part. V.—Black pitch 1 part, yellow wax 1 part, suet 1 part, pounded brick 3 parts. The following has not the inconvenience of requiring to be applied warm, and may be prepared and used without being heated. VI.—Yellow wax 1lb, turpentine 1lb, Burgundy pitch 8oz., mutton suet, 4oz Melt all together and mix thoroughly, and leave them to cool. Form the mass into small balls, as it will not stick to the fingers, and use them when opportunity offers.—*Indian Agriculturist.*

TREES.—The *Cincinnati Commercial* Expains the influence of tree culture on the atmosphere:—"Forests influence the atmosphere, it says, more powerfully by their effect on its general humidity than in any other way. An evaporation of moisture from both earth and trees takes place constantly. The evaporation is greater from open soil than from woodland, but the difference is far more than made up by what is called 'transpiration' of leaves of the trees. This corresponds in a degree to the insensible perspiration of animals. Some conclusive experiments have been made with growing pot plants, going to show that leaves do not absorb moisture, but that, on the contrary, they give it out. Moisture is absorbed through the roots. "The quantity of sensible vapour that is given off through leaves is immense, amounting to one and a quarter ounce to the square foot of leaf surface. The world-old metaphor of counting the leaves of the trees has a new significance in the light of science. Painstaking experiment has enabled those studying the matter to make an approximate estimate of the comparative amounts of vapour given off by earth surface and leaf surface. They have calculated that a square foot of soil sets free about six times as much moisture as a square foot of leaf. The leaf surface is, however, many times greater than the soil surface, so that twice as much evaporation takes place from forests as from open land. When the wood of the country is cut away, therefore, other things being equal, two-thirds of the moisture-giving material of the atmosphere is gone with it. Hence the long fearful droughts on lands bare of trees.'"—*Lumberman's Gazette.* [This seems philosophical and we have never undervalued the influence of trees in a naturally dry and flat country. What we have always denied is that rainfall is lessened by forest denudation in a hill country naturally moist.—ED.]

HOW TO OBTAIN OLD COFFEE, WELL ROASTED AND GROUND, has been a problem more difficult of solution in Ceylon than in countries where coffee cannot be grown. Our readers, especially those at the head of families, will be glad to learn that one so experienced and competent as Dr. Shipton has laid himself out to supply this long-felt want. Dr. Shipton in sending us a specimen tin of good old coffee (with an admixture even of chicory !) writes :—"I am trying to supply what I think has always been a great want in Ceylon, i. e., good *old* coffee prepared for use, as there has always appeared to me great difficulty, first of all in getting the raw product and then in getting servants to properly roast and grind it. I can supply it to the public at 50 cents per lb., and propose making it up in 2 lb. and 3 lb. tins, charging 25 cents each for the tins, which will be soldered. I hope not only to find a good demand for local consumption but that the steamers calling at Colombo may find it convenient to take in a good supply. Perhaps in time a market may also be found in India." We wish Dr. Shipton all the success his enterprize deserves. His name is a guarantee for the excellence of the article he promises to supply. We believe Messrs. J. Walker & Co. manufactured the roaster to be used by Dr. Shipton.

RECENT EXPLORATIONS AND NEW PRODUCTS IN BOLIVIA.—Dr. E. R. Heath, who has recently returned to the United States from South America, reports that he has explored 300 miles of the River Beni to its confluence with the Madeira. Little or nothing had been known of the northern portion of Bolivia until Professor Orton, who met his death in that country a few years ago while prosecuting his surveys, and his successor, Dr. Heath, penetrated this vast wilderness of pampas. The latter gentleman has succeeded in correcting many geographical errors which appeared on the published maps, and reports the river as navigable through its entire length, with the exception of a slight fall at one point. The water of the Beni varies in depth from 27ft. to 500ft. The channel of the stream has been cut through the red clay and gneiss formations to an average depth of 30ft., the walls being in many places vertical. In a few years the vast resources of this country will be developed, and the effects of this inland commerce will be felt by American and European countries. Some of the products of the Beni valley are the rubber tree, which is even now being exported to Europe, but a period of two years and upwards is required to receive returns. Peruvian bark is extensively cultivated in many places on the confines of civilization. One planter owns a forest of 1,000,000 trees, while another is the possessor of 200,000. The supply of Peruvian bark is said to be practically inexhaustible. The finest quality of coffee in the world is raised in this region, and it is believed that its introduction into foreign ports will materially lessen the cost of the staple varieties now in use. Dr. Heath, during his travels, covering several years, came into contact with many savage tribes. He describes one of these as being a white race, but possessing the Indian physiognomy. A tribe of cannibals occupies a portion of the Beni valley, and makes yearly incursions into the neighbouring districts for human flesh. Many of the tribes of this section are entirely nude, while others are provided with but little clothing. Traces of former occupancy are numerous in many places, and hieroglyphics are abundant along the rocky walls of some portions of the river, and in some places he observed that certain characters occurred at high water mark, showing when it was dangerous to navigate the river. Among these devices, of which drawings were made, are a number strongly resembling anchors, though the general character of them is the same as the ancient picture writings found on the rocks in some sections of the western United States. Ruined stone structures are abundant at many points. The fauna and flora of the Beni region include a large number of hitherto undescribed species, and the collections of the former have been placed in the hands of Professor E. D. Cope, the eminent palæontologist, for classification. No published reports of the explorations have yet appeared, but they will be issued in due time.—London *Times*.

LOCAL SALE OF COCOA.—We learn that Mr. J. L. Stipperger has purchased about 16 cwt. of cocoa from the Delgolla plantation, in the Kurunegala district, at very satisfactory rates for the producer. The cocoa was divided into three lots :—about 4½ cwt. 'selected' bought at R55 per cwt. ; about 9 cwt. ordinary at R53 ; and 3¼ cwt. common and light for R30 per cwt. These are very good prices to start the local market with, and must be considered encouraging by all planters of cocoa. We may yet see a large portion of the Kurunegala district under this new product.

A WHITEWASH THAT WILL STICK AND WASH.—We find in a German paper a formula for a wash which can be applied to lime walls and afterwards become waterproof so as to bear washing. Resenschek, of Munich, mixes together the powder from three parts silicious rock (quartz), three parts broken marble and sandstone, also two parts of burned porcelain clay, with two parts freshly slaked lime, still warm. In this way a wash is made which forms a silicate if often wetted, and becomes after a time almost like stone. The four constituents mixed together give the ground colour to which any pigments that can be used with lime is added. It is applied quite thickly to the wall or other surface, let dry one day, and the next day frequently covered with water which makes it waterproof. The wash can be cleansed with water without losing any of its colour ; on the contrary, each time it gets harden, so that it can even be brushed, while its porosity makes it look soft. The wash of calcimine can be used for ordinary purposes as well as for the finest painting. A so-called fresco surface can be prepared with it in the dry way.—*Public Opinion*.

A CORRESPONDENT writing to the *Madras Mail*, recently made certain remarks regarding Neilgherry tea and the prospects of Indian tea planters. Of the former, he observed that for the first week, during which he had used Neilgherry tea, he thought the beverage delicious, but continued use created a dislike which induced him in a few weeks to abandon it altogether. Many of our readers will regard this as an exaggeration. Neilgherry tea, like every other manufactured article, is of many and different qualities. We have tasted the congou of some of the estates enjoying the very best reputation, and have found it the vilest stuff. Planters are in the habit of disposing of tea with defects in manufacture to the local trade and petty dealers, and this damaged stuff not unfrequently is passed off upon customers, who thereupon at once condemn the genuine article. Even the very best tea in a climate like Ootacamund, if not carefully kept, becomes mouldy in a short time, and then yields a most objectionable flavored liquor. We have frequently seen tea that had become mouldy in packets dried in the sun and repacked. The genuine article, of reputed brand and obtained from respectable dealer, produces as fine a tea as any body could wish to drink Some of our friends who have used the tea for years speak in the highest terms of the liquor and strength and of its thorough wholesomeness. The China tea is even here used to flavor a mixed tea. The China leaf has this single recommendation, and for this reason planters cultivate a small patch, with the China plant, and after manufacturing the leaf separately, mix it with the tea of high class hybrid. The separate manufacture seems necessary, as China leaf is hard and does not roll or ferment as rapidly as the leaf of Assam hybrids. The prospects of tea planters are not of the brightest at present ; tea estates are a drug in the market, but an improving future is before them, and a reaction imminent. With expanding consumption, increasing markets and depression in China trade, all the conditions exist for the future prosperity of the tea industry of the Neilgherries.

FUEL.—The *Madras Mail* believes that India's great need is an abundant supply of cheap fuel, which was once cheap and abundant; but the wasteful habits of the natives, who recklessly cut down shrubs and bushes as soon as they had grown a foot or two in height, have completely exhausted the supply. For want of this the smelting of iron, which was once largely carried on in many districts, has almost died out; and other industries, such as pottery, for which artifical heat is indispensable, are also likely to become extinct. The Government has already paid some attention to the matter by the creation of what are known as village forest lands.

COFFEE LEAF FUNGUS.—(Linnæan Society) Mr. F. Crisp, Treasurer, in the chair.—Mr. M. Ward read a paper on his 'Researches on the Life History of *Hemileia vastatrix*, the Fungus of the Coffee leaf Disease.' The phenomena attendant thereon show great analogy to those of the Uredine fungi. The spores, under favourable conditions, viz., moisture, a due supply of oxygen, and a temperature of 75° F., usually germinate in from twelve to twenty-four hours. Complete infection, or establishment of the mycelium in the intercellular passages of the leaf, occurs about the third day after the formation of the germinal tubes. The so-called yellow spot, or ordinary outward visible appearance of the disease, manifests itself about the fourteenth or fifteenth day, but may be delayed, its development and course being dependent on secondary causes, such as atmospheric conditions, monsoons, age of the coffee leaf, &c. By watching the progress of the spots it has been ascertained that the spores therefrom may be continuously produced for from seven to eleven weeks, or even more. Some 150,000 spores have been estimated as present in one yellow cluster, and as 127 disease spots have been counted in one pair of leaves, the quantity of spores thus regularly produced must be enormous. According to amount of diseased spots the sooner the leaf falls, and though young leaves arise the fruit-bearing qualities of the plant necessarily are seriously interfered with. The various sorts of coffee plant are all liable to infection; the only possible remedy is the difficult one of destruction of the spores, and these are supposed originally to have been introduced from the native jungle and rapidly spread under the favourable conditions of artificial cultivation.—*Athenæum.*

WORSE AND WORSE WEEDS.—Sometime ago we mentioned the fact that the flowers of the Ox-Eye Daisy were in such demand by the city florists, that several persons were engaged in forcing them, in order to get them into bloom in early spring, at which time they were sold at a price sufficiently high to pay for the labor expended. When the plants came into flower in the fields, they were offered at every street corner, and were not much in demand. Later, we have seen in the florists' windows, clusters of the flowers of a still worse weed, the Toad-flax (*Linaria vulgaris*), also called "Butter and Eggs," and in some localities "Ramsted weed." This is now justly regarded as one of the worst weeds of our farms, yet the writer can recollect when it was a favorite garden plant. Clusters of this were generally offered by the Broadway florists. Another weed appeared later in the windows, and noticeable from the fact that it is a native. The two plants mentioned above are introduced from abroad, as are the great majority of the weeds of our fields and gardens, but in *Rudbeckia hirta*, the "Thorny cone-flower," we have an undeniable native. This is supposed to have been brought from the West in baled hay; at all events it is now thoroughly distributed throughout the meadows and pastures of the Eastern States; it has come to stay, and makes itself more thoroughly at home from year to year. Like the Ox-Eye Daisy, it belongs to the great Sunflower family. It is much larger and coarser than that; its flowers are much larger, with yellow rays, and the central portion, or disk, of so dark a purple that it is almost black. The stems and foliage are very coarse and beset with rough hairs. To see this miserable weed, the increase of which we have watched with dismay, offered for sale, and to see large clusters of it in the belts of ladies who had purchased it, produced a sensation far from pleasing. It will be curious to watch what effect this sudden bringing into favor of some of our most pernicious weeds will have upon the agriculture of the country.—*Ibid.*

IMPORTANT SALE OF A PLANTATION.—We are glad to learn that Mr. Kettlewell, who was here recently in his yacht, besides investing in Cinchona property in the Maskeliya district, has, through his local agents, purchased the Great Valley estate in Lower Hewaheta for the sum of £14,000 cash with expenditure from 1st April. Great Valley has been the scene of extended cultivation with cinchona under the direction of Mr. E. S. Grigson and the active superintendence of Mr. R. P. Hart, and the plantation has generally been considered as worth a good deal more than the price paid for it. The parties selling have certainly not made their fortune out of it, and the congratulations are rather to be extended to the purchaser on the good bargain he has made.

CINCHONA PROPERTY.—If the Agents of Mr. Kettlewell or any other capitalist want to get a hold of a valuable cinchona property, they ought to look after the sale advertised in another column. The Kenmare estate referred to has been generally regarded as a most promising place, and the neighbourhood is famous for its healthy growth of the usually uncertain but valuable crown bark tree. A correspondent writes:—"Mr. T—— is losing a SPLENDID property just as it is going to give good crops in cinchona bark; hard lines is no name for it. I believe it will go for R33,000 if there is no competition; here 's a chance for men with a little money."—According to the advertisement there is even now 20,000 lb. of cinchona to be harvested, worth, we suppose, from £2,000 to £3,000 sterling!

TEA IN CEYLON.—It is reported that the estimate of crop from Galbodde plantation, Ambagamuwa for the coming season is 5¾ maunds—say 550 lb.—per acre! The tea cannot be more than five years old: when it was between three and four years the yield was equal to 400 lb. per acre. From the Kalutara district we learn that a 2½ year old clearing is estimated to give over 3 maunds, and the prospects of tea in this moist part of the lowcountry are excellent. On Mipitykande, Yatiyantota, the crop for six months of tea now only 2½ years old, has been equal to 160 lb. an acre and for the coming year, 400 lb. per acre will probably be exceeded. To refer to a fourth district, we learn that some tea from Agar's Land, Balangoda, has been pronounced by a home authority as equal to the best Darjiling which is quoted 3s 8d per lb. This gentleman reports:—"I never tasted any tea, India "or China, equal to it for delicacy of flavour and "for strength. The tea plant being a camellia, I wonder "that Ceylon can grow it, as it does best in a cool "atmosphere, I fancy the higher it is grown with you "(as in the case of Arabian coffee and cinchona) the "richer the produce." With the very suitable climate, easy transport and cheap labour enjoyed by the tea planter in Ceylon, he is almost certain to beat competitors in India, in the price at which he can ship his produce. But, cheap as labour is, machinery is still more economical and effectual for the preparing department—a rolling machine for instance doing with 4 coolies what it requires 40 to complete without. When tea rolling, drying, and sifting machines are in full operation on all large plantations and in central factories for the service of limited areas under tea, and when men now beginning to understand the work, have gained the needful experience, there need be no fear of Ceylon holding its own in tea against competitors.

LABOUR IN JAMAICA.—Mr. Valentine Bell, in a lecture on railways in Jamaica, gave a history of the Jamaica railway and compared its working and expense per mile under Government control, with that of the Company who instituted the railway, and gave several reasons why the engineers who had charge of the extension of the Jamaica railway chose to cut the Gibraltar Tunnel. He was sanguine that when the extension was completed the railway traffic would be doubled, and it would be a source of revenue of some advantage to the colony. Notwithstanding the enormous exodus of labourers to the Panama Canal works, there were still plenty of labour to be had, and he was of opinion that labour would be plenty throughout. These works supplied labour to persons who would otherwise be idle. After the lecture advantage was taken, by several persons in the body of the Hall, of the usual "question time" allowed, which gave the meeting the appearance of a political election campaign with the farce of "Heckling" which always winds up the more serious performance. These questioners elicited the fact that male labourers on the railway receive 1s 6d per day and females 1s per day, but the most of the work was task-work which was paid by results. —*Gall's News Letter.*

THE LABOUR QUESTION IN BRAZIL.—There are many questions awaiting the attention of Parliament, whose settlement is of urgent importance. Among these is the old immigration question which assuredly should be delayed no longer. It is not a matter which can be settled in a day, nor a week; it will require the earnest, candid consideration of Parliament for many weeks, for the simple reason that the welfare of immigrants requires reforms in almost every department of legislation. We are convinced that Brazil can secure a large and steady immigration, providing the right inducements are held out, but never under present laws. The immigrant must come as a prospective citizen and property-holder, and he must be assured of every right which his fellow-emigrants enjoy elsewhere. He must be assured beyond all possibility of doubt that there will be no restrictions upon his religious faith, and that no artificial barriers will be placed before him socially and politically. He must be made to feel that the country needs his political and social co-operation just as much as it needs his labor. This question is one which cannot safely be deferred much longer, and the General Assembly will do well to inaugurate the needed reforms at once.—*Rio News.*

COARSE OR FINE TEA PLUCKING.—Of course the younger tea leaf is when plucked the finer the resulting tea. But quantity and price at which planters can afford to sell, have to be considered as well as quality. The *Indian Tea Gazette*, in discussing the question of separate rollings for large and small leaf writes:—

It is most assuredly certain we shall have to abandon the fine plucking so lately recommended; the difficulty pointed out by our correspondent will become less, because the leaf will be more equally coarse: that is to say the percentage of coarse leaf will be out and away above that of the very fine. Whereas we had been told at the commencement of last year that none but first-class teas would do, now we are told that the demand will be for teas which can be sold, at a profit, retail at 2s a lb. or less. And why is this? Because Indian teas are going into more general consumption—which means that the middle classes are drinking them, having found out their merits over Chinas. But still these classes cannot afford to pay, and will not pay, more than a certain price. Thus it seems that, while making a certain percentage of tea for mixing, we shall have to make a larger percentage than before of teas to be drunk pure, and then a little over-fermentation will not prove a matter of so much consequence, as regards the other.

THE YELLOW stain made by the oil used on sewing machines can be removed, if, before washing in soapsuds, the spots be rubbed carefully with a bit of cloth wet with ammonia.—*Queenslander.*

GORSE (OR FURZE, SCOTTICE WHINS) AS A FORAGE PLANT is thus noticed by a writer in the *Field*:—There were some very intelligent farmers in the neighbourhood of Guildford some years ago, and I believe they tried gorse as a forage plant. It grows freely enough and blossoms magnificently, all over Surrey, on the poorest sands. "Agricola" gave many examples in the *Field* of its successful cultivation; and many others have been reported in Staffordshire, where it was given to cows, and in Wales, where it put horses into capital condition. I have seen a report of cavalry horses during the Peninsular War getting nothing but gorse, and doing well on it. It is a plant of strong constitution and vigorous habit, deep-rooted and productive—the best plant in the world, one would suppose, for extracting nutriment from poor soils.

AN AMERICAN COFFEE PLANTING COLONY IN MEXICO.—The Boston *True Flag* of February 18th relates the following concerning the establishment of an American colony in Mexico:—A thoroughly American city has been laid out in the state of Chiapas, Mexico. The site is a beautiful plateau of land, through which runs a never-failing stream of mountain spring water, clear as crystal, full of fish, and affording power for any amount of manufacturing machinery, at an altitude of three thousand feet above the sea-level, on the line of the Mexican Southern railroad. It is called Allen City. Around the city are laid out and taken up twenty-four coffee farms, each touching the city plat. There will be over three million coffee trees in nursery cultivation at this place within the coming year, all to be transplanted and raised to bearing within the next four years. All goods, stores and supplies, agricultural implements, machinery, building material and furniture for the colonists, are exempt from duty, also all exports and imports of productions of the country, and stock for work or breeding purposes, are exempt for ten years. The colonists thus far are from California.—*Rio News.* [The altitude is all right, but, before offering an opinion on the prospects of the coffee enterprize, we should like to know what the average rainfall is and its distribution over the year, also the minimum temperature.—ED.]

CINCHONA AND CACAO IN JAMAICA.—Sir Arthur Musgrave and Mr. D. Morris are doing wonders for the West Indian colony: would that we had some of their energy in high quarters in Ceylon:—

The efforts of the Government of Jamaica to introduce the cultivation of the cinchona tree into that island promise to be as successful as those of the Government of India, and may be expected in time to contribute powerfully to lower the high price of that invaluable drug quinine. Governor Sir Anthony Musgrave, in his report just published, directs attention to the fact that this year the article which used to be known in commerce as Jesuits' or "Peruvian" bark appears for the first time in the list of West Indian exports. The bark sent away during the year, amounting to 23,981 lb., of the stated value of £7,302, was chiefly the produce of the Government plantations. Sir A. Musgrave observes that a great impetus has been given to the cultivation of this valuable tree by the success attending the experiment undertaken by Government, and it may be confidently hoped that in the course of a few years the export of cinchona bark will rank high on the list of exports. It is added that there is a large quantity of land available which is well suited for the growth of cinchona, for the acquisition of which on liberal terms facilities have recently been offered by public notification, the particulars of which have already been set forth in our columns.—*Colonies and India.*

ACTION OF LIGHT ON VEGETATION.

Professor Pringsheim thus sums up the results under this head obtained from a long series of observations:—The primary action of the rays of the sun on vegetation consists in thermic and photo-chemical effects, the influence of which on the separate constituents of the cells is directly recognizable in intense light. The photo-chemical effects relate exclusively to the behaviour of the plant towards the oxygen and carbonic acid of the atmosphere; they are simply changes of intensity in the interchange of gases. These have been fully determined in the case of the absorption of oxygen; less completely in that of carbonic acid. It cannot be shown that light produces any other effect on the plant than the thermic and the photo-chemical. All the action of light on the phenomena of vegetable life, not merely on growth and metastasis, had also the so-called vital and mechanical movements of irritation caused by light, can readily be traced to purely thermic and photo-chemical effects. A more exact knowledge of them requires, however, a special investigation of the behaviour of those constituents of the cells which are sensitive to light, *i.e.*, which are photo-chemically excitable. For an investigation of these, and of their differences from those constituents which are not excitable photo-chemically, the reader is referred to the author's treatises on the functions of chlorophyll and the action of light upon it.—*Pharmaceutical Journal.*

THE LABOUR DIFFICULTY IN JAMAICA.

TO THE EDITOR OF "THE PLANTERS' GAZETTE."

Sir,—It must be a matter of sincere regret to all wellwishers of Jamaica to find that now, after so many years, the old cry of the decadence of Jamaica is raised again at home with as much earnestness and vigour as ever. When such respectable journals as the *Colonies and India* and the *Planters' Gazette* give credence to it, and write leading articles upon it, and when the chairman of the Colonial Bank reiterates it at an annual meeting, it is but natural to think that there must be some foundation for all the statements made.

None, however, is given. They say there is no prosperity in Jamaica because of the "labour difficulty," and they advise us to import coolies from India to remove it. Now, as a matter of fact, there is no "labour difficulty" in Jamaica. The difficulty is purely mythical, and the cry is a delusion and a snare. It was a cry of some force some fifty years ago, but today, with an increase of population equal in proportion to that of the United Kingdom, it is nowhere. If a hurricane of great severity, if a drought of greater intensity, and if unexpected floods disturb—as disturb they must—the prosperity of a purely agricultural colony, the depression which naturally follows is at once ascribed to the old bogey, the "labour difficulty."

It would, no doubt, surprise the writers of the articles in question to learn—and I speak from some experience and knowledge in the matter—that the Jamaica negro, who is paid 1s 3d or 1s 4½d per day, and finds his own hut, food, tools, and medical attendance, is twice as good a labourer as the poor Indian coolie (recommended to us by our mentors), who in Ceylon gets 9d or 10½d per day, but who, in addition, has barracks, tools, rice, blankets and medical attendance found for him. As a tropical labourer, the Jamaica negro is unsurpassed, and he only requires careful and judicious management and prompt payment to make him fully equal to all the labour demands of the colony. On the government cinchona plantations—the most remote and most difficult of access of any plantations in the Blue Mountains—we have had to dismiss this week 60 people, all strong healthy Jamaica negroes, whose services are no longer required. The other day I wished to get some ten acres of forest cleared in another portion of the Blue Mountains, and asked a headman to get a gang for the purpose. In a few days he had 60 men—axemen and others—to do work intended for only about 10 men! If the necessary capital were forthcoming, at least 5,000 acres could be placed under cultivation in cinchona and coffee on the Blue Mountains of Jamaica without importing a single cooly! Where is then the "labour difficulty?"

Is it on sugar estates? The fact that few, if, indeed any, coolies are applied for to the Immigration Department, in spite of two heavy railway contracts in progress, and the departure of 500 labourers for the Panama Canal, shews that the difficulty on sugar estates is as mythical as on the coffee and cinchona estates. If not on the mountains nor in the plains, where is the "labour difficulty" of Jamaica? Surely it can only exist *at home!*—I am, Sir, very faithfully yours,

D. Morris,
Director of Public Gardens and Plantations, Jamaica.

Feb. 24th, 1882.

THE ORANGE TRADE IN THE AZORES.

In a review of the produce of the Azores, dated about the middle of last year, it is stated that the Orange trade shows indications of decline; 220,678 "malote" boxes of Oranges, of the value of £42,312, were exported to England, and notwithstanding this apparently large number the season was stated to be a most disastrous one for St. Michael's, the Orange trade every year getting less and less, and the population emigrating because they are unable to find employment and subsistence. Several circumstances, however, have tended to circumscribe the exportation of Oranges to England: firstly, the old trees have been left, young ones have not been planted in sufficiently large numbers to replace the old ones, and a corresponding diminution of fine Oranges has been the result; secondly, a series of rainy seasons has caused the Oranges to drop off before maturity. Instead of 401,191 "malotes" or flat boxes of Oranges which were exported in 1878, and nearly as many in 1879, only 220 678 were exported last year, being little more than half. On the other hand the anticipated falling-off of the Orange trade has stimulated the cultivation of Pine-apples, which has been raised to 57,232 Pines exported during the season under review against 35,207 and 39,869 exported in 1878 and 1879 respectively. But what has tended more than anything to paralyse the Orange trade with England has been the arrival of Oranges from Valentia in Spain, and the islands of the Mediterranean. In 1872, 417,026 cases of Oranges were exported to Great Britain from Valentia, and in 1878 this trade had increased to 645,000 cases, and no doubt during the last two years the importation of Oranges to England must have been more important. It is stated further that another cause of the diminution of this trade has been the employment of steamships instead of sailing vessels, for one of these large steamers will take six times as many Oranges as the former sailing ships did, and on that score landing in England at one time, and delivering in a few weeks the whole of the Azores crop of Oranges and meeting at the same time the shipments from Valentia the market in England became glutted, and this at a cold winter season when the state of the weather limited the consumption. In 1872 and 1873 steam vessels were purchased by a company in St. Michael's; no doubt the speculation has proved remunerative to the company, but detrimental to the interests of the proprietors of Oranges in the island

and to the public generally, by depreciating the value of the Oranges from St. Michael's, for the arrival of Oranges by steam vessels could be calculated, while that of sailing vessels could not, and the market rigged accordingly. The prices latterly have been so low as to give cause for speculation on the advisability of some other article of export being found to replace the Orange. The Coffee tree has been tried and found to succeed very well—that is, that the trees grow very well in sheltered situations and produce fine Coffee beans, but it has still to be ascertained whether the damp climate of the Azores will allow these beans to be dried sufficiently for exportation. Great difficulty attends the drying of the Indian Corn cobs, but as this cereal forms one of the principal articles of food for the inhabitants and for the towns on the continent of Portugal, the difficulty has been overcome. The Tea plant has also been tried and found successful, and two Chinamen were sent for to teach the means adopted for curing the leaf, which has also to contend with the extremely damp climate of these islands. In doing so it was found that the leaf requires an immense deal of manipulation before it can be presented for sale, and a great part of this manipulation can only be accomplished by mixing up with the hands the Tea leaves. Perhaps some better way may be discovered in process of time when this cultivation comes to be better known; in the meantime the plant thrives very well, and does not appear to require more shelter than the Coffee or Orange trees.—*Gardeners' Chronicle.*

THE CAUSES OF LEAF DISEASE.

TO THE EDITOR OF "THE PLANTERS' GAZETTE."

DEAR SIR,—I have read Mr. Holmes's article on Coffee Leaf Disease in the *Planters' Gazette*. The view he maintains, that cultivated plants tend to become enfeebled by the artificial conditions under which they are grown, has often been suggested. I am very doubtful about the evidence myself. Facts might be easily adduced pointing in exactly the opposite direction.

Many of the points in Mr. Holmes's letter seem to me open to discussion.

From what I know of the habits of *Hemileia*, I see no reason to suppose it would have been less deadly if all the coffee plants in Ceylon had been newly obtained from a wild source. The reasons why the Liberian coffee escapes are not, I think, those suggested by Mr. Holmes, but because the texture of the leaves is unfavourable to the development of the fungus. What I should recommend is, that planters should try to obtain a race of Arabian coffee with similar resisting powers. This might be done by carefully selecting any plants which seemed habitually less diseased, saving and sowing their seed, and repeating the process indefinitely. In this way a strain of seed might conceivably be obtained which would be as little injured by the *Hemileia* as the American vines by the *Phylloxera*. All that is to be said on the present state of the question is contained in Mr. Marshall Ward's last report. It includes some excellent practical suggestions. I should scarcely think this important document can have been seen by Mr. Holmes.—Yours faithfully,

Kew, March 17, 1882. W. T THISELTON DYER.

Mr. Thiselton Dyer's opinions naturally carry great weight from his high reputation and long experience at Kew, but Mr. E. M. Holmes, F.L.S., to whom we thought it only fair to send a proof of the above, remains unconvinced, for he has returned it to us with the following remarks:—

DEAR SIR,—The object of my article on Coffee Leaf Disease was to call the attention of planters to the importance of regarding the subject from more than one point of view. Any *facts* that Mr. Dyer can adduce from his large experience in the Royal Gardens at Kew, to prove, that plants in vigorous health and reproducing freely, are more liable to disease than weakly and badly nourished specimens, will doubtless tend to throw some light upon the question, and open a discussion in your columns, which will, I trust, be advantageous to those interested in coffee planting.

Mr. Dyer seems to assume that Liberian coffee escapes the disease. If he will take the trouble to refer to the *Ceylon Observer*, Feb. 27, p. 186, he will find that Mr. Schrottky's carbolic powder has been used to keep down the disease in the *Liberian coffee nurseries* for a year. I attributed the fact that Liberian coffee is *less subject* to the disease to the plant having had as yet hardly time to have its vitality lowered by excessive bearing, or by growth in soil deficient in metallic nutrition for the plant. Unquestionably Mr. Marshall Ward has done good service as a cryptogamist in throwing light on the life history and development of the fungus, and the best time of year to take preventative measures. Of his report I received an early copy from Dr. Trimen, and am not therefore, as Mr. Dyer presumes, ignorant of its contents. But there are other points of view—for instance, that of agriculture. If it be true, as stated by Mr. Stephen Wilson, that the germs of the fungus are found latent in the seeds of diseased plants; his suggestion of taking the seeds of slightly diseased plants, can scarcely be of any value, unless he be prepared to prove that the disease may be prevented by a process of inoculation, similar in some respects to that which has been practised with such success by M. Pasteur on animals; but I am not aware that this line of experiment has even been suggested. The Joddrell Laboratory at Kew doubtless offers excellent opportunities for an investigation of this kind. I venture to suggest to the assistant director the possible value of experiments with this view.—Yours very truly, E. M. HOLMES.

THE COCOA-NUT AND DATE PALM IN QUEENSLAND.

On the Pioneer River, exactly opposite to the town of Mackay, is to be seen one of the most remarkable sights in all Australia, the cocoa-nut groves of Mr. Barnes. It is some sixteen years since Mr. Barnes conceived the idea of growing cocoa-nuts, and he selected his present homestead with that particular view, and it appears to be eminently suitable for the purpose. The land is a low-lying sandy and vegetable deposit, at one time covered with mangrove trees, and just about on a level with high springtide mark. In fact, dams are made in places in order to keep back these tide waters.

Mr. Barnes has a grove of 1,200 of these beautiful trees now healthily growing upon 10 acres of land. The oldest planted are perhaps some 20 feet in height, but the majority are not yet up to that. The age at which these trees commence to bear fruit varies much, some beginning at four years old, and some not for some eight years later. When once they commence fruiting they continue without intermission—that is, a flower-stem shoots out from the base of every leaf as it is formed, so that fruit in all stages, from the flower to ripeness, will be upon the one tree at the same time The fruit of the cocoa-nut improves with the age of the tree, and these at Mackay are not yet up to their best, therefore Mr. Barnes has not as yet troubled about looking for an export market. The Kanakas on the various plantations buy a large number, so that it pays the proprietor better to sell, say, one-half the produce at a retail price, and let the other half waste, than to hunt for a distant wholesale buyer. For the same reason he has not commenced to dry the

fruit, or express the oil, or utilise the fibre. Thus any selector thinking to go in for cocoa-nut growing will see that it is entirely owing to the circumstance of Mr. Barnes being so close to a large town that the industry has been made to pay.

In these gardens there are many other trees as well, the most noticeable being date palms, of which there are 300 planted. These grow quite as well as the cocoa-nuts, and are equally handsome. Between 300 and 400 orange trees also are planted out, most of which are in full bearing; some of these were evidently suffering from dryness or poverty of the soil, and a great many were injured from having been planted too near the date trees, which rival the bamboo in the way in which their roots ramify and rob the moisture from every neighbouring plant or tree.—*Queenslander.*

PYRETHRUM INSECT-POWDER.

BY C. V. RILEY.

Application of Pyrethrum in Fumes.—The powder burns freely, giving off considerable smoke and an odour which is not unpleasant. It will burn more slowly when made into cones by wetting and moulding. In a closed room the fumes from a small quantity will soon kill or render inactive ordinary flies and mosquitos, and will be found a most convenient protection against these last where no mosquito bars are available. A series of experiments made under our direction indicates that the fumes affect all insects, but most quickly those of soft and delicate structure. This method is impracticable on a large scale in the field, but will be found very effective against insects infesting furs, feathers, herbaria, books, &c. Such can easily be got rid of by enclosing the infested objects in a tight box or case, and then fumigating them. This method will also prove useful in green-houses, and, with suitable instruments, we see no reason why it should not be applied to underground pests that attack the roots of plants.

Alcoholic Extract of Pyrethrum Powder.—The extract is easily obtained by taking a flask fitted with a cork and a long and vertical glass tube. Into this flask the alcohol and pyrethrum are introduced and heated over a steam-tank or other apparatus, The distillate, condensing in the vertical tube, runs back, and at the end of an hour or two the alcohol may be drained off, and the extract is ready for use. Another method of obtaining the extract is by repercolation after the manner perscribed in the American Pharmacopœia. The former method seems to more thoroughly extract the oil than the latter; at least, we found that the residuum of a quantity of pyrethrum from which the extract was obtained by repercolation had not lost a great deal of its power. The first method is apparently more expensive than the other, but the extract is in either case more expensive than the other preparations, though very conveniently preserved and handled. The extract may be greatly diluted with water, and then applied by means of an atomiser. Professor E. A. Smith, of Tuscaloosa, Ala., found that, diluted with water at the rate of one part of the extract to 15 of water, and sprayed on the leaves, it kills cotton-worms that have come in contact with the solution in a few minutes. The mixture in the proportion of one part of the extract to 20 parts of water was equally efficacious; and even at the rate of 1 to 40 it killed two-thirds of the worms upon which it was sprayed in 15 or 20 minutes, and the remainder were subsequently disabled. In still weaker solution, or at the rate of 1 to 50, it loses its efficacy, but still kills some of the worms and disables others. Professor Smith experimented with the extract obtained by distillation, and another series of experiments with the same method was carried on last year by Professor R. W. Jones, of Oxford, Miss. He diluted the extract with twenty times its volume of water, and applied it by means of an atomiser on the cotton-worm and the boll-worm with perfect success. Mr. E. A. Schwarz tried last summer the extract obtained by repercolation, and found that 10 drachms of the extract, stirred up in two gallons of water and applied by means of Whitman's fountain pump, was sufficient to kill all cotton-worms on the plants. Four drachms of the extract to the same amount of water was sufficient to kill the very young worms.

Pyrethrum in Simple Water Solution.—So far as our experiments go this method is by far the simplest, most economical, and efficient. The bulk of the powder is most easily dissolved in water, to which it at once imparts the insecticide power. No constant stirring is necessary, and the liquid is to be applied in the same manner as the diluted extract. The finer the spray in which the fluid is applied the more economical is its use, and the greater the chance of reaching every insect on the plant. Experiments with pyrethrum in this form show that 200 grains of the powder stirred up in two gallons of water is amply sufficient to kill the cotton-worms, except a very few full-grown ones, but that the same mixture is not sufficiently strong for many other insects, as the boll-worm, the larva of the Terias nicippe, and such species as are protected by dense long hairs. Young cotton-worms can be killed by 25 grains of the powder stirred up in two quarts of water. The pyretbrum water is most efficacious when first made, and loses power the longer it is kept. The powder gives the water a light greenish colour, which after several hours changes to a light brown. On the third day a luxuriant growth of fungus generally developes in the vessel containing the fluid, and its efficacy is then considerably lessened.

The Tea, or Decoction.—Professor E. W. Hilgard, of Berkeley, Cal., is the only one who has experimented with pyrethrum in this form, and he expresses himself most favourably as to the result. He says:—"I think, from my experiments, that the tea, or infusion, prepared from the flowers (which need not be ground up for the purpose) is the most convenient and efficacious form of using this insecticide in the open air; provided that it is used at times when the water will not evaporate too rapidly, and that it is applied, not by pouring over in a stream, or even in drops, but in the form of a spray from a syringe with fine holes in its rose. In this case the fluid will reach the insect despite of its water-shedding surfaces, hairs, &c., and stay long enough to kill. Thus applied I have found it to be efficient even against the armoured scale-bug of the orange and lemon, which falls off in the course of two or three days after the application, while the young brood is almost instantly destroyed. As the flower tea, unlike whale soap and other washes, leaves the foliage perfectly clean, and does not injure even the most tender growth, it is preferable on that score alone; and in the future it can hardly fail also to be the cheaper of the two. This is the more likely as the tea made of the leaves and stems has similar, although considerably weaker, effects; and if the farmer or fruit grower were to grow the plants, he would save all the expense of harvesting and grinding the flower-heads by simply using the header, curing the upper stems, leaves, and flower-heads altogether, as he would hops, making the tea of this material by the hogshead, and distributing it from a cart through a syringe. It should be diligently kept in mind that the least amount of boiling will seriously injure the strength of this tea, which should be made with briskly boiling water, but then simply covered over closely, so as to allow of as little evaporation as possible. The details of its

most economical and effectual use on the large scale remain, of course, to be worked out by practice."

The method of applying pyrethrum in either of the three last-mentioned forms is evidently far more economical in the open field, and on a large scale, than the application of the dry powder, and, moreover, gives us more chance of reaching every insect living upon the plant to which the fluid is applied. The relative merits of the three methods can be established only by future experience.—*American Naturalist.*

THE VEGETABLE PRODUCTS OF PARAGUAY.

The following notes, gathered from a recent report by Mr. E. H. Egerton, on the above subject, will give an idea of the character of the economic plants of that country. Paraguay, we are reminded, is but very slowly recovering from total collapse, the result of the depopulation and financial ruin caused by its great war. Two sugar-mills are reported to have started work. The Paraguayan sugar cane is said to contain more saccharine matter than the Tucuman cane. On this subject, however, Mr. Egerton says:—"Though my opinion is not worth anything, the rich alluvial soil of Tucuman seemed to me more suitable for the cane, which certainly grows thicker and more luxuriantly there than in the Paraguayan red sandy soil, fertile though the latter be.

"Paraguay will find it hard to find a market for her sugars, as in Monte Video and the Argentine Republic there are heavy import duties, so that I cannot believe much production of sugar, beyond that for home consumption, will take place in Paraguay."

Tobacco is grown everywhere, but the better quality comes from near Villa Rica. Cigars prepared like Havanas are made there, and there may be considerable increase in the export of these. The taste of nearly all Paraguayan Tobacco is somewhat strong and bitter, which will prevent it fetching high prices. Of undressed Tobacco large quantities are sent to Bremen and other ports of Europe from Asuncion, *via* Buenos Ayres and Monte Video.

Of oil from the indigenous Coco Palm a fair quantity is made. There might be a considerable increase in this article, as there are vast quantities of this tree in the neighbourhood of Asuncion. A quantity of ground-nut oil is produced. It is known as "Mani." It is used as a substitute for Olive oil. The Castor-oil plant, which grows well in Paraguay, is recommended for more extended cultivation in consequence of the oil being valuable for lubricating purposes.

Enormous quantities of Oranges are sent from Asuncion to Buenos Ayres, Paraguay having a reputation for the excellence of its Oranges, which are much superior to those of Corrientes. Most of the gardens contain Banana trees, and there is some export of the fruit. Coffee is grown on a small scale on the northern side of the hills; its flavour is very good, though somewhat strong and bitter. No Wheat seems to be grown, but the native bread, made from the Mandiocca root (Manihot utilissima), is an excellent and wholesome substitute. At present, the newer valuable produce of the country is the Yuba Maté (Ilex Paraguayensis), of which increasing quantities are yearly exported. The Paraguayan Maté, though better than the Brazilian, is not equal to that of the Upper Argentine Misiones.

The wealth of timber is immense, all the hills—and the whole country is hilly—being covered with splendid trees, and all the marshy shores of the Paraguay are a vast forest. When more Basques and Italians arrive the timber trade may become important, and barges full of valuable hard woods may be floated or towed down the river for export. Such hard work as feeling or dressing trees is not very congenial to the native Paraguayan.

Of medicinal plants "Jaborandi" (Pilocarpus sp.) is referred to as being one of the most important, and a plant, of which the native name "Yambayu" alone is known, is considered by the Indians as a cure for asthma. Ipecacuanha is grown in large quantities, but it is said to be distinct and inferior in quality to that from the Brazilian province of Matto Grosso.

Of dyes that obtained from Eupatorium tinctorium is said to be very similar to indigo, though perhaps a little darker. It is a very good dye, and is the blue colour that has long been in use by the Indians. A small sample of this dye lately sent to France for trial is stated to have realised 12 francs, when Indian indigo was sold for 15 francs. The Central American blue dyes have generally been beaten from the field by the Indian indigo; it seems, however, that this Paragnyan shrub is so remarkably prolific and vigorous that it can be stripped of its leaves four times a year without injury to the plants. As it requires but little care or cultivation, this dye plant may some day compete in the European market with that of Indian indigo.

Regarding fibre plants there are many that yield large crops and fibre of good quality. "But," Mr. Egerton says, "by far the best fibre of the country is that of the Caraguatá iberá, a Bromeliacea, which is something like the Pine-apple plant, and which is very abundant in Paraguay, the Misiones, and the Chaco. It is very long and silky, and has long been used by the Indians, and much money has already been spent in endeavours to find some practical machine for the economical preparing of this fibre. I am assured that the desired result has now at length, after a long series of experiments, been attained by a French machine, invented for the purpose, which has just been set up not very far from Asuncion, the process being a simple one without previous maceration. Should this invention prove a success the Caraguatá fibre will become an extremely important article of export, and if half I hear of it be true should compete with advantage against Jute. I am assured, but I cannot vouch for the assertion, that there is immense superiority in the quality of the Paraguayan fibre over that of the Chaco and Misiones Caraguatá."

This plant is referred to in the Kew Report for 1877, p. 37, as a paper material upon which Mr. Routledge had remarked that "Fibre when abstracted no doubt will make good paper." It is also stated in the report to have been determined at Kew to be "one of the singular South American species of Eryngium, which have before flowering quite a Bromeliaceous habit."—F. R. F.—*Gardeners' Chronicle.*

NEW VARIETY OF SILK-MOTH.

On behalf of both entomologists and sericulturists, it seems desirable to make some further mention of the fertile hybrid silk-moth—result of a cross between the *Yamma-mai* of Japan, and the *Tusser* moth of the Deccan—first produced at Bombay about seven or eight years ago (see *ante*, p. 349). It is not mentioned by Mr. Wardle in his valuable "Handbook of the Collection Illustrative of the Wild Silks of India," though that bears date so late as July last year. Besides, this new silkworm, though specially reared, comes under the definition given by Mr. Wardle in his opening sentence:—"The term 'wild silks of India' must be regarded as applying to all species of silk other than that produced by the *Bombyx mori*, the worm which feeds on the mulberry leaf." The primary advantage of this new high-class silk-spinner is in its being able to feed and thrive, not only on the bhair tree (*Zizyphus jujuba*), as mentioned in my remarks the other day, but on almost every variety of the *ficus*—probably on all the trees mentioned by Mr. Wardle (p. 15) as furnishing food to the "Tusser" worm. Thus the

new worm might be diffused over the greater part of India without any planting preparations being required. The Japanese progenitor of the hybrid is known as the "oak-feeding" silkworm; so that may partly account for the omnivorous character of the creature, although experience may show that carefully selected diet will improve the quality of its silk. The new variety might be provisionally designated *Yamma-paphia Mowisia*, thus preserving the name of the ingenious sericulturist, Mr. Paul Mowis, who developed the hybrid, and tested its value through several seasons. Having, myself, seen the creature during all its stages, from eggs to moth, I can testify to its healthy appearance, its fertility, and productiveness. Some millions of its cocoons were, I understood, sent about 1878, to be reeled and worked up at Bradford. The silk is finer than that of the Tusser, and nearly as strong; so that if the worm can be reared and fed on the same plants, and with as little trouble as the coarser Tusser worm, then there should be a very distinct gain in the more valuable quality of silk produced. Mr. Mowis is, at present, carrying on his sericulture somewhere in the railway reserved forests of H. H. the Nizam's dominions; and, no doubt, information could be elicited from him on the subject. He had given much attention to the practical chemistry of sericulture in trying to hit on the best methods of removing the mucilaginous matter from the worms, and in preparing the fibre for dyeing.

Sir George Birdwood's old report (1859-60) on the Tusser and other wild silks of the period (reprinted by Mr. Wardle), though in some respects superseded, gives useful indications of the spirit with which this promising industry should be fostered by the Bombay Government.—W. Martin Wood, West Kensington, February 27th.—*Journal of the Society of Arts.*

TASAR SERICULTURE.

Letter from Major G. Coussmaker, (Tasar Sericulture), to the Secretary to Government, General Department, dated Poona, 3rd February 1882, No. 2.

I have the honor to submit, for the consideration of Government, my report upon the progress made in Tasar Sericulture during the past year as far as the same came under my notice.

1. I cannot yet state that I have succeeded in gathering a full season's crop of cocoons of my own rearing. I certainly had better results last year than in previous years, but still there were many deaths among the silk-worms for which I could not account to my entire satisfaction.

2. I believe that my cages are as perfect and as simple as can be; my plantation has thriven well, and I never thoroughly exhausted my stock of food, though once or twice I fancied that the caterpillars had begun to spin their cocoons before they were quite full grown. I can only imagine that there was some climatic influence which I did not perceive, or against which I was unable to contend with perfect success; or, although the cages kept out rats, birds, lizards, wasps and other enemies of the silk-worms, there may have been some small spiders, mosquitoes or other equally minute enemies which I did not perceive. As it was, I gathered 1,000 cocoons from 270 feet of hedge during the monsoon.

3. I was fortunately able to commence operations at the earliest and most favorable opportunity. My first batch of worms hatched out on 2nd May, and the first cocoon was spun on the 6th June. The last batch of worms hatched in the middle of November, but they gradually dwindled away and came to nothing, the last worm dying on 8th December. A skilful sericulturist might evidently extend the rearing over eight months in the year.

4. The whole season's collection amounted to 60,000, double of what it was in 1880 and collected in the same way. The contribution of the Forest Department amounted to 58,000 against 17,000 in 1880, all gathered in the Northern Division. I had all these cocoons cleaned of extraneous matter, and the result being 200 lb. of clean cocoons for the two years, I sent it all to Mr. Thos. Wardle of Leek. His report will be most valuable, for these are all of this Presidency's production, and the quantity will be sufficient for him to pronounce thereon a decided opinion.

5. In the districts I myself purchased from the villagers about 1,000, which is about what I have been able to do for the past two years in the Ahmednagar Collectorate. Previously I had found them almost entirely on the "Bher" or "Bhori" tree—*Zizyphus Jujuba*; but last year they were found on the "Ain" or "Sádra"—*Terminalia tomentosa*, and the "Karanda"—*Carissa Carandas*. I was at work in the Akola Táluka of Ahmednagar, in a part where the majority of the cultivators habitually manure their seed beds with fresh wood ashes, and where two-thirds of these two trees are pollarded annually or cut back very hard. This cultivation is most favorable to the Tasar worm, for the constant lopping of the trees and burning of the branches and leaves harass the squirrels, birds, lizards, and wasps, while the fresh shoots which spring from the mutilated trees afford the best food possible to the worms. During the short time that I was there I got more perfect cocoons than I have collected elsewhere. I made it a rule to always have a few empty cocoons in my pockets, and when I went out I used to show these to the little village-boys who were tending cattle, telling them to bring me as many as they could, and that I would pay them for so doing. The consequence was that every day when I returned to my tent I used to find three or four children sitting down, waiting for me. I never refused to take the smallest collection, giving them one pie for every two cocoons produced, and they went away exulting in the possession of two or three copper coins. Pretty prompt payment is what is required in this matter, and if the *Wáni*, the village retail dealer, would but take the matter up, the Tasar silk industry would soon be firmly established. The *Wáni* buys these cocoons in the Central Provinces; why should he not take them here to? There is no need for him or any one to kill the chrysalides inside; he has simply to hang the cocoons anywhere where the rats cannot get at them and let the moths escape until he can send the cocoons to Poona, or wherever the market may be. Until village *Wánis* or other independent traders will take the purchasing of the cocoons from the villagers up as a regular business, I fear that we can only look upon the collection of the same as a spasmodic affair fostered by Government officials and carried on by the lower classes for the sake of currying favor with them.

6. As regards the prospects of the Tasar silk industry they are most promising, and every year shows an improvement. Mr. Thos. Wardle has lately drawn up a most complete and minutely detailed account of the "Wild Silks of India" in his "Handbook of the Collection in the Indian Section of the South Kensington Museum." In this he mentions how desirable it is that a trade in Tasar cocoons should spring up, for the uses of this silk are rapidly increasing and the demand is far in excess of the supply; one of the most important uses to which it has been applied is in the manufacture of seal cloth. This beautiful fabric consists of a Tasar silk plush woven into a cotton back and was sold in 1880 at 58s. 6d. per yard. When I was in England in 1873 the highest price obtainable for any fabric manufactured from Tasar was

3s. 6d. per yard. For the manufacture of this seal cloth, yarn spun from the waste and from damaged cocoons is used. In December 1879, I gave over to Government nearly 50 lb. of this yarn manufactured in Bombay by the Alliance Spinning and Weaving Company from cocoons collected in this Presidency. In describing the various purposes for which Tasar silk yarn can be used, Mr. Wardle states, in weaving it into silk carpets he finds that for very many reasons it is superior to Mulberry silk, being lustrous, strong and peculiarly suitable for embroidery.

7. As usual I have sent seed to Mr. Stormont, of the Government Experimental Farm, Bhádgaon, and to Mr. George Baird, at Udepur, for the Mahárána's plantation, and expect to hear some particulars from them soon.

8. I have now laid out one-sixth of an acre as a plantation on one uniform system, and as this seems to answer well, I take this opportunity of describing it for public information. "Lagerstrœmia Indica" *Gul Mendhi* or *Daiyeti* is the best shrub in Poona for the purpose, and I have now planted 906 feet of it in hedges, besides having struck enough cuttings to make nearly as much more. The land is laid out in ridges 7 feet wide with a gutter of 1 foot between. The shrubs are put into a trench of good soil mixed with manure in the middle of each ridge at one foot apart. On each side of these, on the ridges, vegetables of all sorts are being cultivated where the ground is not occupied with the cages, care having been taken to lay out the grounds in the way most suitable for irrigation, and to ensure the most being made of it at all times. The cages are made of rectangular pieces of split bamboo screen work tarred—a very cheap, light material, and when thus protected it is neither liable to be hurt by the weather nor gnawed by rats. In constructing the cages I tie these screens together, making the sides 3 feet high and the ends 6 feet wide. The cage can be put up the whole length of the hedge, and is divided into 12 feet partitions. From side to side, arched over the top of the hedge, are pieces of rattan fastened down at their extremities to the screens, and in the middle to a light ridge pole which rests on triangular screens, stretching across the cage at intervals. Over the hoops thus made coarse open cotton is spread, thus nothing touches the shrubs, for they are uniformly cut to a height of 4 feet and the worms have no inducement to leave their food. The screens under the triangles at the end consist of three, the middle one of which is fixed and the two smaller on either side are fitted with string hinges, thus allowing boys to go in and clean up on both sides of the hedges without injuring the shrubs. The worms are, when hatching, put upon the plants near the door, and they eat away steadily crawling on to the next when their own twig has been stript. As fast as this takes place the bare twigs are cut off and fresh spring forth. In a few weeks' time the hedge is as thick a mass of verdure as it was when the caterpillars were put upon it, and this process goes on as long as the rearing of the worms is continued. As partition after partition gets stript it can be taken down and shifted on further down the hedge or to a new place. An occasional watering is necessary if the weather is not favorable, but as a rule very little irrigation is necessary; still it is as well to have the power at hand if required.

9. I have now spent the R500 placed at my disposal by Government in March 1880; indeed I have spent R67-10 0 over and above that sum, and I hope that Government will now place another sum of R500 at my disposal, the account of which will be as usual submitted to the Accountant-General.

SILK-PRODUCING BOMBYCES AND OTHER LEPIDOPTERA REARED IN 1881.

BY ALFRED WAILLY.

(Membre-Lauréat de la Société d'Acclimatation de France.)

By referring to my reports for the years 1879 and 1880, which appeared in the *Journal of the Society of Arts*, February 13th and March 5th, 1880, February 25th and March 4th, 1881, it will be seen that the bad weather prevented the successful rearing in the open air of most species of silk-producing larvæ. In 1881, the weather was extremely favourable up to the end of July, but the incessant and heavy rains of the month of August, and beginning of September, proved fatal to most of the larvæ when they were in their last stages. However, in spite of my many difficulties, I had the satisfaction of seeing them to their last stage. Larvæ of all the silk-producing Bombyces were preserved in their different stages, and can be seen in the Bethnal-green Museum. In July, when the weather was magnificent, the little trees in my garden were literally covered with larvæ of more species than I ever had before, and two or three more weeks of fair weather would have given me a good crop of cocoons, instead of which I only obtained a very small number. The sparrows, as usual, also destroyed a quantity of worms, in spite of wire or fish-netting placed over some of the trees.

On the trees were to be seen—*Attacus cynthia* (the Ailanthus silkworm), the rearing of which was, as usual, most successful; *Samia cecropia* and *Samia Gloveri*, from America; also hybrids of *Glovercecropia* and *Cecropia-Gloveri*; *Samia promethea* and *Telea polyphemus*; *Attacus pernyi*, and a new hybrid, which I obtained this last season by the crossing of *Pernyi Roylei*. For the first time I reared *Actias selene* from India, on a nut tree in the garden, and *Attacus atlas*, on the ailanthus. The *Selene* larvæ reached their 5th and last stage. The *Atlas* larvæ only reached the 3rd stage, and were destroyed by the heavy rains; only two remained on the tree till about the 8th or 9th of September, when they had to be removed. I shall now reproduce the notes I took on some of the various species I reared.

Actias Selene.—With 60 cocoons I only obtained one pairing. The moths emerged from the beginning of March till the 13th of August, at intervals of some duration, or in batches of males or females. I obtained a pairing of *Selene* on the 30th of June, 1881, and the worms commenced to hatch on the 13th of July. The larvæ in first stage are of a fine brown-red, with a broad black band in the middle of the body. The second stage commenced on the 20th of July, larvæ of a lighter reddish colour, without the black band; tubercles black. Third stage commenced on the 28th of July; larvæ green; the first four tubercles yellow, with a black ring at the base; other tubercles, orange-yellow. Fourth stage commenced on the 6th of August; larvæ green; first four tubercles golden-yellow, the others orange-red. Fifth stage commenced on the 19th of August; first four tubercles yellow with a black ring at the base; other tubercles yellow, slightly tinged with orange-red; lateral band brown and greenish-yellow; head and forelegs dark brown. As stated before, the larvæ were reared on a nut-tree in the garden, till the last stage. *Selene* feeds on various trees—walnut, wild cherry, wild pear, &c. In Ceylon (at Kandy), it is found on the wild olive-tree. As far as I am informed by correspondents in Ceylon, this species is not found—or is seldom found—on the coasts, but *Attacus atlas* and *Mylitta* are commonly found there.

Attacus (antheræa) Roylei (with 60 cocoons); three pairings only were obtained, and this species I found the most difficult to pair in captivity. Two moths emerged on the 5th of March, a male and a female,

and a pairing was obtained; but the weather being then too cold, the ova were not fertile, the female moth, after laying about 200 eggs, lived till the 22nd of March, which is a very long time; this was owing to the low temperature. The moths emerged afterwards from the 8th of April till the 25th of June. A pairing took place on the 2nd of June, and another on the 6th of June.

Roylei (the Himalaya oak silkworm), is very closely allied to *Pernyi*, the Chinese oak silkworm, the *Roylei* moths are of a lighter colour, but the larvæ of both species can hardly be distinguished from one another. The principal difference between the two species is in the cocoon. The *Roylei* cocoon is within a very large and tough envelope, whilst that of *Pernyi* has no outer envelope at all. The larvæ of *Roylei* I reared did not thrive, and the small number I had only went to the 4th stage, owing to several causes. I bred them under glass, in a green-house. A certain number of the larvæ were unable to cut the shell of the egg.

Here are a few notes I find in my book :—Ova of *Roylei* commenced to hatch on the 29th of June; second stage commenced on the 9th of July. The larvæ in the first two stages seemed to me similar to those of *Pernyi*, as far as I could see. In second stage, the tubercules were of a brilliant orange-red; on anal segment, blue dot on each side. Third stage, four rows of orange-yellow tubercles, two blue dots on anal segment, brilliant gold metallic spots at the base of the tubercles on the back, and silver metallic spots at the base of the tubercles on the sides. No further notes taken.

One of my correspondents in Vienna (Austria) obtained a remarkable success in the rearing of *Roylei*. From the 25 eggs he had 23 larvæ hatched, which produced 23 fine cocoons. The same correspondent, with 35 eggs of *Samia Gloveri*, obtained 20 cocoons. My other correspondents did not obtain any success in rearing these two species, as far as I know.

Hybrid Roylei-Pernyi.—I have said that it is extremely difficult to obtain the pairing of *Roylei* moths in captivity. But the male *Pernyi* paired readily with the female *Roylei*. I obtained six such pairings, and a large quantity of fertile ova. The pairings of *Roylei* (female) with *Pernyi* (male) took place as follows: two on the 21st of May, one on the 3rd of June, two on the 4th of June, and one on the 6th.

The larvæ of this new hybrid, *Roylei-Pernyi*, contrary to what might have been expected, were much easier to rear than those of *Roylei*, and the cocoons obtained are far superior to those of *Roylei*, in size, weight, and richness of silk. The cocoon of my new hybrid has, like *Roylei*, an envelope, but there is no space between this envelope and the true cocoon inside. Therefore, this time, the crossing of two different species (but, it must be added, two very closely allied species) has produced a hybrid very superior, at least to one of the types, that of *Roylei*. The cocoons of the hybrid *Roylei-Pernyi* seem to me larger and heavier than any *Pernyi* cocoons I have as yet seen.

The larvæ of this new hybrid have been successfully reared in France, in Germany, in Austria, and in the United States of North America. The cocoons obtained by Herr L. Huessman, one of my German correspondents, are remarkable for their size and beauty. The silk is silvery white.

I have 17 cocoons of this hybrid species, which number may be sufficient for its reproduction. But the question arises, Will the moths obtained from these cocoons be susceptible of reproduction?

In my report on Lepidoptera for the year 1879, I stated, with respect to hybrids and degeneracy, that hybrids had been obtained by the crossing of *Attacus Pernyi and Attacus Yamma-Maï*, but that, although the moths (some of which may be seen in the Bethnal-green Museum), are large and apparently perfect in every respect, yet these hybrids could not be reproduced. It must be stated that these two species differ essentially in one particular point. *Yama-Maï* hybernates in the *ovum* state, whilst *Pernyi* hybernates in the *pupa* state. The hybrids hybernated in the *pupa* state. *Roylei*, as *Pernyi*, hybernates in the *pupa* state.

In the November number, 1881, of "The Entomologist," Mr. W. F. Kirby, of the British Museum, wrote an article having for its title :—"*Hermaphrodite-hybrid Sphingidæ*," in which, referring to hybrids of *Smerinthus* and *populi*, he says that hermaphroditism is the usual character of such hybrids.

I extract the following passage from his article :—"I was under the impression that hermaphroditism was the usual character of these hybrids; and it has suggested itself to my mind as a possibility, which I have not, at present, sufficient data either to prove or to disprove, that the sterility of hybrids in general (still a somewhat obscure subject) may perhaps be partly due to hybridism having a tendency to produce hermaphroditism."

Now will the moths of my new hybrid *Roylei-Pernyi* (which I expect will emerge in May or June, 1882), have the same tendency to hermaphroditism as has been observed with the hybrids obtained by the crossing of *Smerinthus populi* with *Sm. ocellatus*? I do not think that such will be case with the moths of the hybrid *Roylei-Pernyi*, on account of the close relationship of *Roylei* with *Pernyi*, but nothing certain can be known till the moths have emerged. Here are the few notes taken on the hybrid *Roylei-Pernyi*. Ova commenced to hatch on the 12th of June; these were from the pairing which had taken place on the 21st of May. Larvæ, black with long white hairs. Second stage commenced on the 21st of June. Larva, of a beautiful green; turbercles orange-yellow; head dark brown. Third stage commenced on the 1st of July; 4th stage on the 7th. Larva of same colour in those stages: tubercles on the back, violet-blue or mauve; tubercles on the sides, blue. Fifth stage commenced on the 18th of July. Larva, with tubercles on back and sides, blue or violet-blue. First cocoon commenced on the 10th of August. Want of time prevented me from taking fuller and more accurate notes.

Attacus Atlas.—For the first time, as stated before, I attempted the rearing of a small number of *Atlas* larvæ in the open air on the Ailanthus tree, but had to remove the last two remaining larvæ in September; the others had all disappeared in consequence of the heavy and incessant rains. These larvæ were from eggs sent to me by one of my German correspondents. The pairing of the moths had taken place on the 17th of July, and the eggs had commenced to hatch on the 4th of August.

I had about 80 cocoons of another and larger race of *Atlas* imported from the Province of Kumaon, but only eight moths emerged at intervals from the 31st of July to the 30th of September. Not only did the moths emerge too late in the season, but there never was a change of obtaining a pairing. In my report on Indian silkworms, published in the Nov. number of the *Bulletin de la Société d' Acclimatation*, for the year 1881, compiled from the work of Mr. J. Geoghegan, I reproduce the first appendix of Captain Thomas Hutton, to Mr. Geoghegan's work, in which are given the names of all the Indian silkworms known by him up to the year 1871.

Of *Attacus atlas*, Captain Hutton says:—"It is common at 5,500 feet at Mussoorie and in the Dehra Doon; it is also found in some of the deep warm glens of the outer hills. It is also common at Almorah, where the larva feeds almost exclusively upon the 'Kilmorah' bush or *Berberis Asiatica*; while at Mussoorie it will not touch that plant, but feeds exclusively upon the large milky leaves of *Falconeria insignis*. The worm is, perhaps, more easily reared than any other of the wild Bombycidæ."

I will now quote from letters received from one of my correspondent in Ceylon, a gentleman of great experience and knowledge in sericiculture.

In a letter, dated 24th August, 1881, my correspondent says:—"The *Atlas* moth seems to be a near relation of the *Cynthia*, and would probably feed on the Ailanthus. Here it feeds on the cinnamon and a great number of other trees of widely different species; but the tree on which I have kept it most successfully in a domestic state is the *Milnea Roxburghiana*, a handsome tree, with dark-green ternate leaves, which keep fresh long after being detached from the tree. I do not think the cocoon can ever be reeled, as the thread usually breaks when it comes to the open end. I have tried to reel a great many *Atlas* cocoons, but always found the process too tedious and troublesome for practical use.

"The *Mylitta* (Tusser) is a more hardy species than the *Atlas*, and I have had no difficulty in domesticating it. Here it feeds on the cashew-nut tree, on the so-called almond of this country (*Terminalia catappa*), which is a large tree entirely different from the European almond, and on many other trees. Most of the trees whose leaves turn red when about to fall seem to suit it, but it is not confined to these. In the case of the *Atlas* moth, I discovered one thing which may be well worth knowing, and that was, that with cocoons brought to the seaside after the larvæ had been reared in the Central Provinces, in a temperature ten or twelve degrees colder, the moths emerged in from ten to twenty days after the formation of the cocoon. The duration of the *pupa* stage in this, and probably in other species, therefore, depends upon the temperature in which the larvæ have lived, as well as the degree of heat in which the cocoons are kept; and in transporting cocoons from India to Europe, I think it will be found that the moths are less liable to be prematurely forced out by the heat of the Red Sea when the larvæ have been reared in a warm climate than when they have been reared in a cold one.

"I do not agree with the opinion expressed in one of your reports, that the short duration of the larva stage, caused by a high temperature, has the effect of diminishing the size of the cocoons, because the *Atlas* and *Tusser* cocoons produced at the sea-level here are quite as large as those found in the Central Provinces at elevations of 3,000 feet or more. According to the treatise on the "Silk Manufacture," in "Lardner's Cyclopædia," the Chinese are of opinon that one drachm of mulberry silkworms' eggs will produce 25 ounces of silk if the caterpillars attain maturity within 25 days; 20 ounces if the commencement of the cocoons be delayed until the 28th day; and only 10 ounces if it be delayed until between the 30th and 40th day. If this is correct, a short-lived larva stage must, instead of causing small cocoons, produce, just the contrary effect."

In another letter, dated Nov. 25th, 1881, my correspondent says:—"I am sorry that you have not had better success in the rearing of your larvæ, but you should not despair. It is possible that the choice of an improper food-plant may have as much to do with failures as the coldness and dampness of the English climate. I lost many thousands of *Atlas* caterpillars before I found out the proper tree to keep them on in a domesticated state; and when I did attain partial success, I could not keep them for more than one generation, till I found the *Milnea Roxburghiana* to be their proper food plant. I do not know the proper food-plant of the *Mylitta* (*Tusser*), but I have succeeded very well with it, as it is a more hardy species than the *Atlas*. Though a *Bomby.x* be polyphagous in a state of nature, yet I think most species have a tree proper to themselves, on which they are more at home than on any other plant. I should like, if you could find out from some of your correspondents in India, on what species of tree *Mylitta* cocoons are found in the largest numbers, and what is about the greatest number round on a single tree. The *Mylitta* is common enough here, but there does not seem to be any kind of tree here on which the cocoons are to be found in greater numbers than twos and threes; and there must be some tree in India on which the cocoons are to be found in much greater plenty, because they could not otherwise be collected in sufficient quantity for manufacturing purposes. The *Atlas* is here found on twenty or more different kinds of trees, but a hundred or a hundred and fifty cocoons or larvæ may be found on a single tree of *Milnea Roxburghiana*, while they are to be found only singly, or in twos and threes, on any other tree that I know of. The *Atlas* and *Mylitta* seem to be respectively the Indian relations of the *Cynthia* and *Pernyi*. It is, therefore, probable that the Ailanthus would be the most suitable European tree for the *Altas*, and the oak for the *Mylitta*."

Attacus Mylitta (*Antheræa paphia*).—I did not receive a single cocoon of this species for the season 1881. My stock consisted of seven cocoons, from the lot received from Calcutta at the end of February, 1880. Five were female, and two male cocoons, one of the latter died, thus reducing the number to six. The moths emerged as follows:—One female on the 21st of June, one female on the 26th, one female on the 28th, one female on the 1st of July, and one male on the 3rd of August; the latter emerging 34 days too late to be of any use for rearing purposes. The last female moth emerged, I think, about the end of September. These cocoons had hybernated twice, as has been the case with other Indian species. I had Indian cocoons which hybernated even three times.—*Journal of the Society of Arts.*

THE INFLUENCE OF LIME IN THE GERMINATION OF SEEDS.—Some interesting results of experiments by Dr. Liebenberg as to the influence of lime on the germination of seeds, have resently been published by that gentleman in the *Journal* of the Vienna Academy of Sciences. It appears that the seeds of many plants require the presence of lime in the soil during the germinating process or the seedlings die for the want of it. It is shown also that many other plants do not fail to germinate freely and well without the presence of lime in the soil. Dr. Liebenberg also points out that plants which fail to grow through the absence of lime in the soil do not fail in consequence of the injurious effects of any other matters that may be present, but because lime is essential to their healthy growth.—*North British Agriculturist.*

THE TIMBER OF BRITISH COLUMBIA.—Professor Dawson, of the Dominion Geolgical Survey, in a report on the forests of British Columbia, draws attention to the vast importance of the timber supplies of the Province. He states that many first-class mills have been established in various parts of the country, and the total annual product is stated to be about 200,000,000 feet, of which 25 million feet are exported to other countries, 25 million feet used at home, and 150 million feet sent to California. He estimates that 110 million acres (or two thirds of the whole Province) are covered with timber. The Douglas fir, or Oregon pine, is the most valuable commercial tree. It frequently exceeds eight feet in diameter, and rises to a height of from two to three hundred feet, forming great and dark forests. The western hemlock and the red cedar are the next most important trees of the Province, both of them, the latter especially, growing to a great size. The importance of these vast reserves of timber, as well as of the mineral resources of the Province, will become more apparent as settlement extends westwards from Manitoba towards the Rocky Mountains. The construction of the Canada Pacific Railway will also develop the mineral and timber resources of the Province.—*Colonies and India.*

SELECTIONS FROM THE NON-OFFICIAL FORMULARY OF THE DUTCH SOCIETY FOR THE ADVANCEMENT OF PHARMACY.

Extractum Cinchonæ (De Vrij) (*Liquid Extract of Cinchona*).

Red cinchona (bark of stem of *Cinch. succirubra*, grown in Java or India, and containing at least 6 per cent of alkaloids), in fine powder	100
Normal hydrochloric acid (volumetric standard)	38
Glycerin	20
Water	362

Macerate the cinchona with the acid and water for twelve hours, occasionally stirring. Whenever the foam has disappeared add the glycerin and transfer the whole to a percolator, the orifice of which is closed with a linen plug. When the liquid runs off clear continue the percolation with water until the liquid is no longer precipitated by solution of soda, and evaporate the percolate on the water-bath until it amounts to 100 parts.

The extract is clear, bright yellow, and yields a clear solution with water. 10 parts of the extract, mixed with a solution of 1 part of acetate of sodium or potassium in 6 parts of water, yield a copious, light flesh-coloured precipitate of kinotannate of quinetum. The quantity of this precipitate, when collected on a filter, washed with a little water and dried on the water-bath in a tared capsule, should amount to 0·7 parts. When mixed with a large quantity of strong alcohol the extract becomes very turbid and deposits a viscid, colourless calcium salt. If this is not the case too much acid has been used in its preparation.

Extractum Cinchonæ Spissum (De Vrij) (*Inspissated Extract of Cinchona.*)

Evaporate the liquid extract of cinchona on the water-bath until the weight does not diminish any more sensibly. 100 parts of the liquid yield about 57 parts of the inspissated extract.

It is of the consistence of thick honey, yellowish-red, and yields a clear solution with water in all proportions.—*New Remedies.*

THE INDIAN CINCHONA FEBRIFUGE.

On several occasions we have referred to reports as to the results following the administration of the alkaloidal mixture prepared in India from red bark, and which is now used largely in India under the name of "cinchona febrifuge." For although success in the attempt to provide a cheap and effective substitute for quinine sulphate would prove a vast boon to suffering multitudes in our Eastern possessions, its effects would not be limited to them, but would extend to other parts of the world. A communication to the *Medical Times and Gazette*, of March 18, from Dr. James Irving, formerly Surgeon-General in the Bengal Army, enables us to quote a few details which will supplement those already published.

Dr. Irving states that the "febrifuge" is now extensively used in Bengal and Bombay, and that during the year 1880-81 as much as 9,296 lb. were manufactured, according to Mr. Wood's process, at a cost of rather less than 18*s.* 6*d.* per lb. Oddly enough, however, it does not seem to gain much favour in Madras, although the preparation formerly made by Mr. Broughton was in repute there. Dr. Irving says, too, that when the preparation was first issued for use in Bengal, and probably also in Bombay, there was undoubtedly a strong prejudice on the part of medical officers against it, owing to its disagreeable taste and smell, but chiefly to its tendency in some cases to produce nausea and even vomiting, as well as an uncomfortable feeling of griping, which were attributed to the presence of amorphous alkaloid.

Recently an abstract has appeared of a series of reports of the medical officers in the North-West Provinces and Oudh, where the febrifuge has been tried for a year in gaols, police hospitals and dispensaries, alternate cases being treated with quinine. All the reports testify that the preparation is of undoubted therapeutic value in the treatment of ordinary malarious fever, and is an excellent tonic in small doses; but the most of them indicate that it is inferior to quinine in every respect and not trustworthy in the treatment of severe cases of intermittent or remittent fevers. Disagreeable gastric symptoms are said to occur in about one-third of the cases in which it is administered, but a combination of sedatives and aromatics has been found to obviate these symptoms.

Dr. Irving concludes by saying that there is no denying that disagreeable effects not very uncommonly follow the use of this remedy, and that although some medical officers have spoken favourably of it, they are generally opposed to the use of the febrifuge for European soldiers. He therefore thinks it very desirable that, if possible, the obnoxious principle should be removed. But even as it is, he considers the introduction of the febrifuge has been a great boon to the people of India, as it is very much cheaper than quinine and infinitely superior as an antiperiodic to any of the indigenous drugs.—*Pharmaceutical Journal.*

NITROGEN IN SOILS: PRACTICAL CONCLUSIONS.

Messrs. Lawes and Gilbert.

1. Most of the nitrogen of farm-crops is derived from the nitric acid of nitrates within the soil.

2. The nitric acid in the soil is produced from the nitrogenous compounds of the soil itself, from the nitrogenous organic matter of animal and vegetable-manures, from the ammonia of artificial-manures, and from the ammonia supplied by rain and condensation from the atmosphere. A very small quantity of ready-formed nitric acid is supplied by rain and condensation from the atmosphere. Nitric acid is also provided by the direct application of nitrates.

3. The ammonia of ammonium-salts is rapidly converted into nitric acid in the soil, as also is the nitrogen of some organic matters, such as urine. The nitrogen of rape-cake, that of the less soluble parts of farmyard-manure, of stubble, of roots, &c., is much more gradually converted into nitric acid, and it may require many years for the conversion of the whole of it. The nitrogenous compounds of the soil itself are very slowly converted into nitric acid, but the soil yields a certain quantity every year.

4. When there is no vegetation, and there is drainage from the land or even when there is vegetation, and excess of drainage, nitric acid is lost by drainage.

5. As in the case of permanent grass-land the soil is always covered with vegetation, there will be with it the maximum amount of nitric acid utilised by the crop, and the minimum amount lost by drainage. Land without vegetation will be subject to the maximum loss of nitric acid by drainage.

6. The power of a growing crop to utilise the nitric acid in the soil is much diminished if there be a deficiency of available mineral constituents, and specially of potash and phosphoric acid, within the reach of the roots.

7. As the various crops grown upon a farm differ very much as to the period of the year of their most active growth, the length of time they remain on the land, and the character and the range of their roots, their capacity for taking up nitric acid from the soil is very different.

8. The recognised exhausting character of corn crops is largely due to the limited season of their active

growth, and the long period during which the land is bare, or there is little growth, and so subject to loss of nitric acid by drainage.

9. When salts of ammonium, or nitrates, are applied as manure, the chief, if not the only unexhausted residue of nitrogen left within the soil available for future crops, is that in the increased roots and other residues of the crops; and this is only slowly available.

10 When oilcakes or other foods are consumed by stock, the formation of nitric acid from the manure produced is slower, but continues longer than when salts of ammonium are used. When there is a liberal use of animal-manures, an accumulation of nitrogenous and mineral matter takes place in the soil, and such accumulation is known under the term "condition." Under such circumstances the fertility of the soil is maintained, or it may even be considerably increased.—*Journal of the Royal Agricultural Society of England.*

NURSERY TREATMENT OF PLANTS.

All young trees before being removed to plantations should be transplanted from the seed-beds into positions in the nursery approaching, where practicable, those into which they are ultimately to be transferred, and the state of the plants ought to be regulated to suit the soil and site. Thus for bare and exposed tracts small robust plants well furnished with fibres are necessary, larger ones with similar roots for those less exposed, and for sheltered positions, with a good open loam, those with moderately furnished roots will answer, provided they are able to sustain their vigour; but for open, sandy, and stiff, tenacious soils the plants cannot be too well rooted. I will not enter here into the question of the most suitable sizes of plants for planting, and need only state that this must be regulated by attendant circumstances, just as exposure, the nature of the ground, and the natural covering that may be growing upon it.

In my opinion the non-stability of the trees, where that exists, is not traceable to any elaborate treatment they receive in their younger stages, but in some case it may be owing, especially with conifers, to the manner of performing the necessary operations in the nursery. As already stated, the roots ought to spread out equally all round the plant, and not, as frequently is the case, all on one side, for when such are planted, by some of the methods at present in vogue, they are placed permanently in the ground with their roots directed in one direction, so that fresh roots require to strike out from the base of the plant in an opposite one, and they never attain the same vigour and strength as the others; it is therefore not surprising that numerous trees are heeled over when a strong wind strikes them from a point opposite to that of their roots.

The methods adopted when transplanting in the nursery are "dibbling" and "laying," but to have properly formed roots these operations must be efficiently carried out. In the case of small coniferous plants, with a nursery soil of a loose and open character, dibbling is to be preferred before laying, as better developed roots are formed if they are dropped direct down in the opening formed by the dibble; but if the opening so made is not of sufficient capacity, either as to depth or width, the roots inevitably get doubled up with their points near the surface, which causes them to be of an unnatural form, and thereby hurtful for a time to the growth of the plants and to the further development of their underground ramifications. Laying is performed by cutting a trench in the form of a right or acute angle, deep enough for the roots of the plants to be inserted, and to project direct down to their full extent, and when that is done they will be formed in a natural manner; but when the trench is opened, as is too often done, to a depth quite insufficient for the requirements of the roots, the consequence is that they are placed at something like a right angle to the stem, and when not covered in that position they are generally doubled up and pressed against the face of the trench by the operator when pressing in the loose soil to cover them, so that they become shaped according to the way in which they are placed; and, if they be again transplanted, the contortions of the roots are further aggravated. I do not mean to aver that when such are planted and growing in plantations they will not be capable of withstanding storms of wind, but they will be more ready to succumb than those whose roots have been grown in a form more nearly approaching those in a natural state.

There are particular soils on which plantations are more liable to suffer than on others, such as those of a loose, open, and thin character, and on thin soils with a cold, tenacious, or impervious stratum underneath; on these, whether the trees have grown there direct from seed, from seedlings planted there, or from plants prepared in the nursery, they would be equally liable to suffer.

In conclusion I may state that what ought to be more looked to in treating plants in the nursery is greater attention and care in transplanting, so that roots may be produced of a more natural formation, and when they are transferred from there to the forests they should be placed in the ground in as natural a position as possible.

With a view to nullify the effects of winds upon plantations, belts of trees, which are most capable of weathering the storms, should be planted on all their most exposed boundaries, and particular attention must be paid to these, if they are to be of any benefit, both in their arrangement when planting, and in after years. Trees of a low-growing habit ought to be kept on the outer margin, and taller ones behind, and they should never be allowed to become crowded together, but have plenty of room for encouraging the development of side branches, and extending their roots underground. Hillocks and ridges might also be taken advantage of, where these would be likely to afford shelter to other portions of the plantation, arranging and treating the trees upon them for that purpose.—Andrew Slater Jun., Wyreside Cottage, Lancaster.—*Journal of Forestry.*

BIOLOGY AND AGRICULTURE.

Recent advances in our knowledge of the lowest forms of life have tended to bring into prominence not only their relation to disease but to the ever-increasing importance of the part which they play in our arts and idustries. Probably in none of the industrial arts, save those concerned with fermentation, commonly so called, has the progress of this branch of biology shown such remarkable development as in its bearing on the art of agriculture.

It was even been suggested that a *bacterium* is at the bottom of the present state of agricultural depression, and there is a considerable amount of force in this suggestion. The loss of nitrogen from the in the form of nitrate is one of the most serious difficulties with which the farmer has to contend; and, as this loss takes place by the washing out of nitrates in the drainage and its diffusion into the subsoil below the reach of the roots of plants, it is necessarily greater in wet seasons such as have been the rule for the last few years.

We believe that Pasteur was the first to suggest, twenty years ago that the process of nitrification going on in soils and waters might be due to the agency of an organism; but it was not until the last five years that the researches of Schlösing and Müntz and of Warington conclusively showed that this is the case and that the organism is a *bacterium*. This *bacterium* is present in all fertile service soils and

under the proper conditions of temperature, moisture, supply of oxygen, and presence of salifiable base is continually converting ammonia and nitrogenous organic matter, which has passed the putrefactive stage, into nitrates. The nitrates are the chief form from which most crops and especially the cereals assimilate their nitrogen is now admitted generally, even by the few physiologists who still cling to the belief that plants can assimilate free atmospheric nitrogen; the very great use of this nitrifying organism is thus apparent. It may be remarked in passing that this Schizomycete is able to effect a change in a mineral substance, ammonia, causing its oxidation into nitric acid, all other known organised ferments being concerned in the transformation of organic bodies, and this is an operation hitherto unsuspected in the life of any Bacteria.

Nitrification takes place in soils most rapidly in the hot months of the year, and as a cereal crop assimilates little or no nitrogen after June, but merely transfers that already taken up and present in the roots, stems and leaves to other organs, it follows that, on a cornfield, in the late summer and the autumn months, nitrate will be formed and, will, in the event of wet weather, be readily washed out of the soil.

Observations made during many years at Rothamsted, and recently published by Messrs. Lawes, Gilbert, and Warington,* show the extent to which this loss of nitrates may occur. They find that on land uncropped and unmanured, that is, a bare fallow, during 4 years 1878-1881, nearly forty-two pounds of nitrogen per acre per annum, equal to nearly two and a half hundredweight of ordinary nitrate of soda, was lost by drainage. They also estimate that on land under continuous wheat cropping from ten to twelve pounds of nitrogen per acre per annum was lost by drainage from plots which received no nitrogenous manure. When nitrogen is applied in the manure, considerably larger quantities are lost in the drainage, and this is exclusive of that diffused into the lower layers of soil below the reach of plant roots, and of that which may under certain conditions be lost by deduction to elementary nitrogen.

In an ordinary rotation the loss of nitrogen will be considerably less than in these experiments, for crops will often be growing for months after the cereal crop is removed, and thus conserve the available nitrogen and store it up for future use. It is however obvious, that, with a bare fallow favouring the production of nitrates, followed by a wet season, a very considerable loss of available nitrogen will occur through loss of nitrates, and it becomes a matter for the farmer to consider whether it is to his advantage, for the sake of cleaning his land, to take the risk of this loss and supply the nitrogen at a cost, in ammonia, salts, or Chili saltpetre, of nearly a shilling per pound, or on the other hand, adopt some system of cultivation and cropping by which much of the loss may be obviated. On some soils the growth of an autumn green crop would save most of the nitrates and leave the land in fair condition for a succeeding crop; naturally the decision as to the advisability of such a course must rest in each case with the individual farmer.

The Agricultural mind appears to always require a panacea from the scientific man before it will accept his results as of any use. At a recent meeting of the Farmers' Club it was observed by a leading agriculturist, that, although Mr. Lawes (now Sir J. B. Lawes) had discovered the way in which nitrogen was lost he had not told the farmer how to retain the good effects of nitrogenous manures in adverse seasons. The discovery of the manner in which the loss occurs is, however, an immense step in the right direction, and moreover Lawes and his colleagues have clearly shown that with a growing crop on the land the loss is very greatly lessened.

This *bacterium* of nitrification is but one of a great number of the lower forms of life now engaging the attention of scientific men, which are, or ought to be, of immense interest to the scientific pursuit of agriculture. The researches of Pasteur on the life history of *Bacillus* of Anthrax, Aitken and Hamilton's investigations now being conducted into the causes producing braxy and louping ill: and the study of the organisms concerned in the changes which occur during the souring of milk and the ripening of cheese are kindred studies bearing in a direct manner on the daily practice of the farmer. Of no less interest too is the biological work done by Kühn and Liebscher, which has traced the *beet sickness* to the presence of a Nematode, while the investigations into the life history of *Hemileia vastatrix*, the too well-known coffee leaf disease, the *Plasmidiophora*, which is the proximate cause of *anbury* in turnips, and the fungus of potatoe disease, all point to the growing relation between the kindred sciences of biology and agriculture. Illustrations might be multiplied almost indefinitely, but these are of sufficient importance to show that the work of the microscopist and biologist has a wide and deep influence, first of all on the practice of agriculture, and through it on the comforts and the pockets of the consumers at large.—*Nature*.

CULTIVATION OF CINCHONA IN THE UNITED STATES.

In response to the resolution presented in the House of Representatives, relative to the growth of cinchona trees in the United States, published in the *Oil and and Drug News* on May 9, the following letter was received from the Commissioner of Agriculture:—

Washington, May 12, 1882.

In reply to the above resolution I have the honor to state that for the past sixteen years the Department of Agriculture has annually distributed cinchona plants, some seasons to the amount of many hundreds, and that the reports received afford but little hope for success except in Southern California, and, so far, no trustworthy experiments have been made in that region.

Some of the species will live in Southern Florida, notably *cinchona succirubra*, which is one of the most robust, as also one of the most useful; but the climate of that State is not considered so promising for the establishment of an experimental plantation as the higher lands of Southern California.

Dr. J. Elliott Howard, of England (high authority in everything relating to the cinchona), in the transactions of the Linnean Society, remarks that "it must be remembered that these are mountain plants, loving free air and alternate mist and sunshine, while the hot, close atmosphere of the lower lands is always injurious to their perfection as quinine-producing plants.

The object sought to be obtained by the Department in its distribution of cinchona plants was that of making practical tests in the most promising localities in regard to their permanent introduction; this being the only safe method of procuring such information.

The climactic conditions under which the cinchona flourishes in its native habitats have been repeatedly described and are now comparatively well known. The management of an artificial cinchona plantation is now as well understood as is the management of an orange group.

In the India cinchona plantations the best results are said to be obtained in a warm, equable, and very moist atmosphere, at elevations where the mean yearly temperature indicates 64° Fahrenheit, and in those established in Saint Helena the plants flourish well at an elevation of 1,500 feet above sea level, in rich lands, bathed in moisture, the mean temperature for the year being 60°.

It is shown in the reports of the Signal office that the mean temperature for the year at San Diego is 60°, the

highest monthly mean reaching 68° in August, and the lowest monthly mean being that of 53°, in January and February. So far as thermometric figures indicate atmospheric temperature, the climate of San Diego corresponds with that of St. Helena; but it is well known that the thermometer alone is not a safe guide in comparisons of this kind, the hygrometrical condition of the atmosphere being of equal, if not of greater, importance as regards vegetable growth, and here, as elsewhere, a well-conducted practical test with the growing plants will settle the question of adaptability.

This, as well as many other questions of similar import, could readily be answered by this department if means for doing so were placed at its disposal, and where lands in suitable locations could be made available in carrying out, under special instructions emanating from and controlled by this Department.

GEO. B. LORING, Commissioner.

P. S.—I enclose herewith a communication addressed to my predecessor on the subject of cinchona, under date of December 20, 1880.

SALEM, COLUMBIANA COUNTY, OHIO, December 20, 1880.

SIR,—In accordance with my offer when in your office a few days ago, I send you the following copy of my letter to you under date of July 7 of the present year, which seems to have been lost:

* * * * * *

I have shown that this tree is not strictly tropical, as you suppose it to be, but belongs to the cold climate (*tierra fria*). The cinchona belt begins at the limit of that of the orange, banana, coffee, bamboo, &c. You say that it will not bear the slightest touch of frost, but I have explained that the whole cinchona region is liable to a visitation of frost any night of the year, and that considerable ice is formed in some parts of it. There is, perhaps, no forest tree that runs up into a higher, and therefore colder, region of the Andes.

I suspect that your plants have been killed by heat, rather than by cold. I would expect to succeed by selecting a site on the mountains above the range of the trees above mentioned. This would be the rule within the tropics, and one would suppose that it would hold good in any other region where the cultivation was at all possible. Certainly, few localities could be less congenial to this tree than the hot, flat and water-soaked soil of Florida.

A study of the literature of the subject as found in England in connection with the forthcoming thermometric and hygrometric reports of the present year would place the Department in a position to judge with considerable accuracy as to the manner of conducting experiments and the probability of a favorable issue in a given locality. I would always be ready to assist so far as my own observations in the Andes might be of value.

WILLIS WEAVER.

In the Report of the Agricultural Department for 1879, a correspondent in Elk Grove, Sacramento County, California, inquired whether an attempt has ever been made to naturalize the cinchona in the warmer parts of the United States; and whether it is probable that the tree could be raised in California, the climate of which, he remarks, "is suitable for oranges, lemons, figs, olives, and other tropical fruits; and, proceeding to reason upon this erroneous basis, he urges that our government ought not to be behind that of England, which has successfully introduced cinchona into its East and West Indian colonies. Mr. Le Duc, then Commissioner of Agriculture, replied as follows:—

We have advised our correspondent of the unsoundness of his position in regard to the climate of California, and that oranges, lemons, figs and olives, not being tropical fruits, afford no criterion of climate in the premises; and further, that if our government had tropical climates within its control, as has that of England, it might with some propriety be urged to make efforts to introduce tropical plants, and especially such plants as are peculiarly valuable, and strictly tropical, as cinchona is believed to be.

The various climates of our widespread country, however, embrace no locality that can be called tropical, and but is adapted to the cultivation of tropical products, whatever may be the range or degree of temperature. It is alleged, we know not with how good reason, that there are localities in California and Florida where frost is never experienced; and hence the conclusion is ignorantly or unadvisedly reached that all the conditions of a tropical climate exist, and that the productions of such a climate are possible. This quite common error leads to embarrassment, and often to disappointment, and as the Department has frequent occasion to notice, gives rise to inquiries for information and to requests for seeds and plants which would otherwise be avoided. There are other conditions of vegetation within the tropics than that of mere absence of frost, conditions upon which plants strictly tropical absolutely depend, and in the absence of which, whatever the temperature may be, they cannot be expected to succeed. It has been stated that in some of the most southern counties of England an occasional winter will pass without the thermometer ever dropping below the freezing point. Still it cannot, we think, from this casual occurrence, be concluded that England, or any portion of it, has a tropical climate.

With regard to cinchona, the Department has in former years grown plants of several species, and distributed them in Southern California, and in several of the Southern States, more particularly Florida. The results of experiments made with these plants, have been in all cases unfavourable, owing to adverse climatic conditions, showing that the plant will not stand the slightest degree of frost without injury. The locality of San Diego, California, is the only one in the United States which affords any promise of success, and the uncertainty and doubt in respect of that would not warrant the Department in a continuous effort to introduce the cultivation. In a word, after many years of trial, the Department considers the prospect of successfully growing cinchona as being too unfavourable to authorize any further distribution of plants, or any special attempts to establish its production among us.

It is believed that Commissioner Le Duc, in the above, did not treat the question with knowledge of the subject, and further experiments will continue to be made by Commissioner Loring.—*Oil and Drug News.*

A SLEEPING TREE.—A tree was recently brought from Australia to Nevada, which has been in the habit at night of going to roost like the chickens. The leaves fold together, and the ends of the tender twigs coil themselves up like the tail of a well-conditioned pig. After one of the twigs has been stroked or handled, the leaves move uneasily, and are in a sort of mild commotion for a minute or more. Indignant at having been transplanted the other day, it had hardly been placed in its new quarters before the leaves began to stand up like the hair on the tail of an angry cat, and soon the whole plant was in a quiver.—*American paper.*

THE AMERICAN JAPAN TEA MARKET.—Regarding the importation of Japan teas into the American tea market by American buyers, the *Japan Herald* writes as follows:—The American tea market seems destined to operate as a caution and a warning to the direct trade enthusiasts, by which they ought not to fail to profit, unless they are singularly obtuse. In the course of only two months during last season it was asserted, and passed uncontradicted, that importers lost no less than three million dollars by their operations, and this year telegrams to hand convey the intelligence that the first parcels of new season's tea show a loss of from seven to eleven cents per pound. These facts prove how reckless the competition of buyers is, and that large sums of money pass into Japanese pockets, which would never find their way there if business, on the part of foreign tea buyers, were conducted on more rational principles, or if the Japanese were to carry out to its full length the direct shipment theory, in which in the absence of experience, seem to have so much faith.—*Indian Tea Gazette.*

INDIA :—CROP AND WEATHER REPORT.

FOR THE WEEK ENDING 11TH JULY 1882.

GENERAL REMARKS.—The rainfall of the week has been general throughout the country (excepting the Madras Presidency, from which no reports have been received). In Coorg the rainfall has been excessive ; in the Mysore State extremely heavy in parts and sufficient everywhere ; in the Bombay Presidency heavy in some places, good in others, and light in a few talukas of three districts ; in the Nizam's territories fair ; in Berar good ; in the Central Provinces good everywhere, and heavy in two districts ; in the Central India States good on the whole ; in the Rajputana good in some districts, fair in others, and none in Peshawar ; in the North-Western Provinces and Oudh heavy in Rohilkund, good or fair in other districts and light in the eastern tracts ; in Bengal good nearly everywhere, though light in one or two places ; in Assam good in all districts, though in one more is wanted ; in British Burmah good generally, but in some localities apparently still short.

General prospects are satisfactory on the whole. In Coorg the ragi crops are being weeded and paddy, where not flooded, is doing well ; in the Mysore State standing crops are in good condition and sowings are in progress ; in Berar and the Nizam's territories the sowing of kharif crops is either progressing or completed ; in the Bombay Presidency sowings have mostly been completed and in some places transplantation has commenced ; in the Central Provinces the kharif sowings have been completed in parts and continue in others, and the transplanting of rice is progressing in the eastern districts ; in the Central India and Rajputana States ploughing and sowing are progressing; in the Punjab kharif sowings continue in some districts, and have commenced in others ; in the North-Western Provinces and Oudh the kharif crops have come up well in places and sowings are still in progress in others ; in Bengal the sowing of the autumn crops is still going on in Behar, elsewhere the transplanting of winter rice on low lands is proceeding, and sugarcane, early rice, and jute are doing well ; in Assam and British Burmah ploughing and sowing are still in active progress.

BENGAL.—Rain fell in all districts during the week ; prospects generally favourable, but more rain is wanted in some places for cultivation of winter rice, especially on high lands ; transplanting of winter rice on low lands proceeding; sugar-cane, early rice, and jute promising ; in Behar sowing of autumn crops still going on ; cholera has almost disappeared from many places, but is still prevalent in Birbhoom, Chittagong, and Sonthal Pergunnahs ; fever is said to be increasing in parts of Nuddea, but is abating in Darjeeling Terai.

ASSAM (CACHAR).—Weather very warm and sultry ; sowing of dumahi and murali crops finished ; ploughing for sali crops continues ; common rice 21 5-16th seers per rupee ; tea doing well ; no more cholera cases reported.

MYSORE AND COORG.—Rain has fallen generally throughout the Mysore State ; heavy floods in the Cauvery, Henavaji, and Zegachi rivers ; the Tongabadra in the Shimoga district has overflowed its banks in many places ; standing crops everywhere in good condition ; agricultural operations in active progress ; ragi, *Kartik* paddy, balar. &c., being sown ; prospects favourable ; prices—ragi 25½ seers per rupee in Bangalore, 20 seers in Mysore, 23 to 36 in Shimoga, 32 to 44 in Chitaldrug ; public health good.—*Pioneer.*

NEW VARIETY OF SUGAR-CANE.

A communication, interesting in itself, and specially to inasmuch as it must have been one of the last matters to engage the attention of our great naturalist, Darwin, was read before the Linnean Society at its last meeting. The subject was the production of a new variety of Sugar-cane by a process of apposition, and which opened up the whole question of Graft Hybridisation. The paper was forwarded to Mr. Darwin by a Brazilian planter, with a record of confirmatory experiments by Dr. Glasl, Director of the Botanic Garden of Rio Janeiro, and communicated to the Linnean Society. According to the statements made in the paper, duly and formally attested by a number of planters, a new variety had been produced by taking two cuttings of different varieties of Sugar-cane, dividing the cuttings in halves lengthwise, and then tying the cut surface of one-half of the one to the corresponding surface of the other. Then by means which we need not detail, but but which seem to be similar to the *greffe à double bouture* of the French, and which is employed for propagating Aucubas, union is effected, and a new bud or shoot produced, possessing, not characters intermediate between the two varieties, but characters sufficient to lead the authors to speak of it as an entirely distinct variety—a circumstance which leads us to think the experimenters are attempting to prove too much.

In addition to the sworn testimony photographs were sent, but from the slight inspection we have been enabled to make of them, we should not deem the evidence they afford as sufficiently conclusive. Of course there is no reason whatever to doubt the perfect good faith of the writers ; but in a case of such importance it is only right to require that the evidence they lay before us should be made as rigorous as possible, so that misinterpretation of facts should be as far as possible excluded. Gardeners in general who, or their ancestors, have practised the art of grafting from time immemorial, are almost without exception unanimous in their verdict against the possibility of graft hybridisation ; but, on the other hand, they must and do admit the existence of some modifications, else the utility of grafting at all would, to a large extent, be negative. The truth seems to be that physiological differences are produced—the stock acts in this way on the scion, and to a less degree the scion on the stock. It is needless to give illustrative instances, as they are familiar to every gardener, and we have so often adverted to the matter in these columns, and given so many illustrative cases, that it is needless now to repeat them.

It must be admitted that, as a rule, the changes produced are chiefly physiological, actual changes of form so marked as to be obvious to the unaided vision being relatively few. Still they do exist, and if the proportions they bear to the enormous number of cases in which no such visible effect is produced is apparently infinitesimal, yet the presumption is that as marked physiological change can hardly exist without change of structure, so it is only the imperfection of our vision and the coarse methods of our observation which prevent us from seeing it. If this be admitted, and we think it must be, the possibility of graft hybridisation must be admitted also. Then such cases as that of the Cytisus Adami, of the Potato, of the Vine (several cases), of the Pear, and of many others which have been recorded in these pages from time to time are, taken as a whole, inexplicable upon any other hypothesis. The numerous cases where a variegated scion has communicated its properties to a green-leaved stock, of which we have also seen numerous cases, are sufficient to prove the reality of the reciprocal influence, though it is perhaps not fair to adduce a constitutional defect as a case of graft hybridisation properly so called.

We believe, then, that graft hybridisation is quite possible—nay, that it does occur ; but under all the circumstances of the case we are justified in demanding the most rigorous evidence possible before we can admit that any individual case which may present itself is really attributable to hybridisation of this character. Grafting of any kind in the case of monocotyledons is indeed of doubtful possibility. It is true we have

heard of the grafting of Dracænas, and we have heard of flute-grafting in the case of some grasses, but we do not think in either case that the evidence is free from suspicion. These matters demand careful experiment and most minute and patient examination, and there are few matters that might more profitably attract the attention of experimenters with the requisite intelligence, skill, and patience. The matter would not be of purely scientific interest, but clearly also of practical value. We trust, therefore, that instead of having to rely, as we do now, on a very few isolated examples which occur to us, as it were, by accident, we may in the future have a body of evidence, founded on careful experiment, and from which all sources of doubt and fallacious interpretation may be banished.—*Gardeners' Chronicle.*

PEARLS owe their lustre to their being composed of fine layers which allow light to pass through them, whilst the numerous layers, lying one under the other, disperse and reflect the light in such a manner that it returns and mixes with that which is directly thrown back from the outer surface.—*Progress.*

FUNGI.—Not very long ago, Sir James Paget pointed out that much might be learned by the surgeon from a study of morbid growths in plants. Gardeners are now returning the compliment, and acknowledge that they may learn from the medical man how to study the life history of the microscopic fungi which infect plants, and the nature of the minute ferments which convert insoluble inert salts into soluble nitrates fit for the food of the plant.—*Pharmaceutical Journal.*

CINCHONA ALKALOIDS.—It has been observed by Dr. Hagar that the ingestion of the cinchona alkaloids and morphia is better tolerated by the stomach when accompanied by an excess of hydrochloric acid. Some experiments that he has made lead him to the same conclusion with respect to chinoline. He found that upon taking tartrate of chinoline in the pill form, without acid, in doses of 0·5, 0·75 and 1·5 gram, it always produced distrubance of the stomach and a dull singing in the ears. The same quantities of tartrate of chinoline made up into pills with 0·25, 0·4, and 0·8 gram of the official hydrochloric acid, when taken and followed by half a glass of water, did not cause the unpleasant symptoms.—*Phramaceutical Journal.*

DOES LIBERIAN COFFEE PAY?—This is a question mooted by an Indian contemporary in a brief paragraph on the subject, and he proceeds to answer it to some extent in the negative, for no other reason than that the cultivation of the variety does not seem to have made much progress in any of the countries into which it has been introduced. So far as Ceylon is concerned, we should say it has succeeded in nearly every locality where it has been planted, and so far as bearing goes, nothing could be better than the Liberian estates in Ceylon. That this new product has not taken with planters so readily as some others, may be attributed to two reasons. One of these probably is that the coffee stocks being excessive, it is not desirable to increase them; secondly, many localities which are unsuitable to Liberian coffee are favourable to other new products such as tea, cocoa, cardamom, and hence these latter have had the preference with most Ceylon men. Moreover the decided success which has attended the last-named cultivations, has encouraged planters to continue them, and so long as this is the case, tea is bound to have the preference over coffee as a lowcountry product. It is true that in one locality, that of Kalutara, Liberian coffee and tea are thriving side by side, and we may venture to say both equally well. Kalutara tea bids fair to take a high position in public estimation, a sample having recently been valued at 2s 2d per lb.—*Ceylon Times.*

QUASSIA CUPS are now largely made in Boston, Massachusetts. One firm there last year worked up fifty tons of the wood (*Picræna excelsa*), which is obtained from Jamaica, and costs about £5 per ton. Four years ago the price was £12 per ton, but it has steadily declined as well as that of the bitter cups which have dropped from 12s. to 4s. per dozen. —*Journal of Applied Science.*

THE ADELAIDE BOTANIC GARDENS.—Dr. Schomburgk's annual report on the establishment under his direction contains as usual many features horticulturally interesting. Amongst plants of special botanical interest are mentioned three species of Landolphia, named respectively Kirki, Petersianum, and Watsoni. These Landolphias are woody climbers, belonging to the Apocineæ, and are natives of the east and west coast of tropical Africa. They are the producers of a caoutchouc of excellent quality, known as "African rubber," which forms a large article of export. It is only lately that these three species have been botanically described and named. Dr. Schomburgk fears they are not suited to the dry climate of Adelaide, but will, no doubt, thrive at Port Darwin. There also will the "Rain Tree," Pithecolobium Samao, be likely to succeed; it has been growing luxuriantly in the shade-house. We note amongst the novelties Bertholetia excelsa, the tree which furnishes the well-known Brazil nuts; Nectandra Rodiei, a noble tree belonging to the Laurineæ, a native of British Guiana, where its bark is considered a febrifuge. The new Museum of Economic Botany has been appreciated more than Dr. Schomburgk ever expected; young and old take a lively interest in the many objects exhibited, which show how the vegetable products can be turned to account for our use as articles of food, construction, medicine, or art, which knowledge is the more readily obtained by exhibiting the economical and commercial plants in their raw state side by side with the articles into which they have been converted by the labour and skill of man.—*Australasian.*

TONGA PLANT.—Mr. N. E. Brown, in the *Gardeners' Chronicle* (February 11, p. 180), gives a detailed account of the tonga plant, *Rhaphidophora vitiensis*, Schott. This gentleman, who has paid especial attention to the aroid group remarks that the plant is involved in great confusion botanically. In his opinion it is identical with *R. Pinnata*, Schott, and with *Epipremnum mirabile*, Schott, the last name being the one he prefers to retain for the plant. It is stated to be a widely distributed plant, occurring in Java, Sumatra Baly, Amboyna, Timor and Tropical Australia, and has been in cultivation by Mr. Bull, at Chelsea, since 1878, but was not then recognized by Mr. Brown, who saw it in flower, as identical with *Raphidophora vitiensis*. According to Rumphius ('Fl. Amboynensis,' vol. v., p. 489, t. 183, fig. 2), the natives of Java and Baly cook "the horns," or terminal buds of the flowering stems, a little over the fire, and bruise them and squeeze out the juice, which is given to lean and feeble horses and cows, and is said to bring them into a fat and healthy condition. The internal substance is pounded and used in the form of a poultice as a remedy for sprains. Cows feed upon the leaves, especially during the hot months when the fields are destitute of grass; they seem to be very fond of them and also of the stems, as these are not acrid. Mr. N. E. Brown attributes the identification of tonga to Baron Mueller. This is scarcely correct, the first identification being that by E. M. Holmes in May, 1880 (*Pharmaceutical Journal*, [3], x., p. 889), of *Rhaphidophora vitiensis*, by comparing the starch found in tonga with the starch found in a fragment of the stem of that plant. The other plant, *Premna taitensis*, was first identified by Dr. Hansen Erch, who visited the Fiji Islands on purpose to discover the plants.—*Pharmaceutical Journal.*

CARBOLIC ACID AND CARBOLATE OF SODA in doses of from 15 to 20 grains daily have been used by M. Raymond (*Practitioner*, Feb., p. 126, from *Journ. de Méd.*) in the treatment of typhoid fever, with the result of a notable lowering of temperature, lasting as long as six hours; he did not, however, find that the duration of the fever was shortened by the treatment. M. Hallopeau reports more favorable results, as he found that the effects of carbolate of soda in lowering the temperature lasted for many days, and he believes that it did exercise an influence on the duration of this disease. M. Raymond says that he has also obtained excellent results from the use of carbolic acid in erysipelas; he uses a 50 per cent solution as a lotion, and administers carbolic acid internally and carbolate of soda in injections.—*Pharmaceutical Journal.*

COTTON SEED AS MANURE.—One of the advantages of feeding sheep on oilcake is that the nitrogenous constituents of the diet are conveyed to the soil in the shape of manure; but it appears to have only recently occurred to any one to try the experiment of using cotton-seed as a manure by direct application. The idea seems to have originated in the United States, where cotton-seed meal applied to poor cotton lands increased the productiveness of the cotton crop eightfold. Land, which before the use of this cotton-meal as a fertilising agent yielded only 18 bales per acre, is said to have been so improved by its application as to have produced 145 bales to an acre. The interesting question arises, whether this remarkable result is due to any particular connection between the chemical properties of the manure and those of the crop—both being identical? It would be important to decide this point by trying cotton-meal as a manure for different crops. It is a well-known fact that a manure which will suit one plant will disagree with, or produce smaller effects on, another, and cotton-seed meal may not give such startling results as those above quoted if applied to other agricultural produce. But the experiment is worth trying. It would, if the American reports may be relied upon as accurate, prove invaluable, at least in India, Queensland, Fiji, the West African Settlements, and other cotton-producing parts of our Empire, even if it did not succeed on other crops.—*Colonies and India.*

TEST FOR GOLD.—In the present great search for gold in Ceylon the following test, taken from the *Public Opinion*, will be read with interest:—"There is a simple method for the detection of gold in quartz, pyrites, &c., which is not generally described in the mineralogical text-books. It is an adaptation of the well-known amalgamation process, and serves to detect very minute traces of gold. Place the finely-powdered and roasted mineral in a test tube, add water and a single drop of mercury: close the test tube with the thumb, and shake thoroughly and for some time. Decant the water, add more and decant repeatedly, thus washing the drop of mercury until it is perfectly clean. The drop of mercury contains any gold that may have been present. It is therefore placed in a small porcelain capsule and heated until the mercury is volatilsed, and the residue of gold is left in the bottom of the capsule. This residue may be tested either by dissolving in aqua regia and obtaining the purple of Cassius with protochloride of tin, or by taking up with a fragment of moist filter paper, and then fusing to a globule on charcoal in the blowpile flame. It is being shown that gold is much more universally distributed than was formerly supposed. It has recently been found in Fulton and Saratoga counties, New York, where it occurs in pyrites. It has also been discovered in the gravel of Chester Creek, at Lenni, Delaware County, Pa. In one of the Virginia gold mines wonderful richness is reported. 160,000 dols. worth of pure gold having been taken from a spe of three square feet."

A SIGN OF THE TIMES.—One marked effect of the low prices which prevailed in 1880 has been to stimulate a demand for our medium and cheap qualities, as well as to permanently increase the price paid for them, so that now common grades show an advance of about 30 per cent, while fine teas exhibit a falling-off of fully half as much. It is believed that fine sorts will remain permanently weakened, and that the tea of the future in most general demand will be one which can be retailed at from 2*s.* to 2*s.* 6*d.*—*Indian Tea Gazette.*

THE LARGEST TREE.—The biggest tree in the world is not in California, as every one supposed, but in Australia. The champion of the Yosemite Valley must give way to the peppermint trees on the Dandenong range of hills in Australia. Baron von Müller, who is a great authority on botanical subjects, asserts that he has seen one of the trees of the enormous height of 480 feet, almost equalling the height of St. Paul's Cathedral.—*Land and Water.*

A COCOA-NUT GROVE IN QUEENSLAND.—On the Pioneer River, exactly opposite to the town of Mackay, is to be seen one of the most remarkable sights in all Australia, the Cocoa-nut groves of Mr. Barnes. It is some sixteen years since Mr. Barnss conceived the idea of growing Cocoa-nuts, and he selected his present homestead with that particular view, and it appears to be eminently suitable for the purpose. The land is a low-lying sandy and vegetable deposit, at one time covered with Mangrove trees, and just about on a level with high springtide mark. In fact, dams are made in places in order to keep back these tide waters Mr. Barnes has a grove of 1,200 of these beautiful trees now healthily growing upon 10 acres of land. The oldest planted are perhaps some 20 feet in height, but the majority are not yet up to that. The age at which these trees commence to bear fruit varies much, some beginning at four years old, and some not for some eight years later When once they commence fruiting they continue without intermission—that is, a flower-stem shoots out from the base of every leaf as it is formed, so that fruit in all stages, from the flower to ripeness, will be upon the one tree at the same time. The fruit of the Cocoa-nut improves with the age of the tree, and these at Mackay are not yet up to their best, therefore Mr. Barnes has not as yet troubled about looking for an export market. The Kanakas on the various plantations buy a large number, so that it pays the proprietor better to sell, say, one-half the produce at a retail price, and let the other half waste, than to hunt for a distant wholesale buyer. For the same reason he has not commenced to dry the fruit, or express the oil, or utilise the fibre. Thus any selector thinking to go on to for Cocoa nut growing will see that it is entirely owing to the circumstance of Mr. Barnes being so close to a large town that the industry has been made to pay. In these gardens there are many other trees as well, the most noticeable being Date Palms, of which there are 300 planted. These grow quite as well as the Cocoa-nuts, and are equally handsome. Between 300 and 400 Orange trees also are planted out, most of which are in full bearing; some of these were evidently suffering from dryness or poverty of the soil, and a great many were injured from having been planted too near the Date trees, which rival the Bamboo in the way in which their roots ramify and rob the moisture from every neighbouring plant or tree. Many Bananas and Pine-apples are grown, and Mr. Barnes adopts the safe plan of frequently changing the ground upon which he grows these, and also plants them wide distances apart. Melons in great quantities are also grown, and are ripe in early September. As this is a full month sooner than they appear in the Brisbane market, doubtless a trade will some day be carried on in the way of the North exporting them to the South. —*Queenslander.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(London Price List, July 6th, 1882.)

IMPORTED FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White	Slightly softish to good hard bright	£6 10s a £8
Yellow	Do. drossy & dark ditto	£5 a £6
CINCHONA BARK—		
Crown	Medium to fine Quill	4s a 6s per lb.
	Branch	2s a 3s
,, Red	Medium to good Quill	2s a 3s
	Branch	1s 6d a 2s
,, Twig		5d a 9d
CARDAMOMS, Malabar	Clipped, bold, bright, fine	6s a 7s
	Middling, stalky & lean	3s 6d a 5s 6d
Aleppee	Fair to fine plump clipped	4s a 5s
Madras	Long, lean, to fair	2s 6d a 4s 6d
Mangalore	Good & fine, washed, bgt.	6s a 8s
Ceylon	Middling to good	2s 6d a 3s 6d

"TRAVELS OF PLANTS": THE COCONUT, COFFEE, AND PLANTAINS *VS.* BANANAS.

We do not know what position in the botanical world is occupied by "H. E.," who wrote the article on the migration of plants, which will be found on page 82 (Vol. II.), but, amidst much that is exceedingly interesting, he tells us some things which have surprized us. For instance, taking the leading botanists of the world as our authorities, we have hitherto pinned our faith to the belief that the coconut palm was a native of South America, whence the nuts floated to the East Indies, including Ceylon; the isles of the Pacific, &c. But we are now astonished at being told that, while the Eastern hemisphere is indebted to the Western world for such products as the potato, the cinchonas, tobacco, wheat and maize (chillies and a good many other plants might be added to the list), it was the Eastern world which, with sugar and coffee, gave to the Western the boon of the coconut palm! We thought, too, it had been finally settled as an article of botanical belief, that coffee is indigenous to Africa, and that what is called *Coffea arabica* reached Arabia Felix from its home in Abyssinia, at a period not very far back in history. Travellers in Abyssinia and in Africa generally, especially western and central Africa, have found varieties of the coffee plant growing abundantly in the primitive forests, while we are unaware of any evidence that coffee has ever been seen in any part of Arabia, except as a cultivated plant,—generally requiring and obtaining irrigation. Are we now to believe, on the authority of this writer in the *Gardeners' Chronicle*, that "*Coffea arabica*" is not a misnomer but a correct indication of origin? Is it true also that forced growth, the result of excess of sun, accounts for rust in wheat? We are inclined still to believe that wheat rust, like the allied fungus of the coffee leaf, flourishes chiefly where there is excess of moisture. The fact that innumerable seedlings of aspen sprung up around Moscow after the conflagration which checkmated the Corsican invader is of great interest, but it is not singular. In Australia, myriads of seeds of *eucalypti* and *acacias* which have lain in the soil inert, perhaps for generations, vivify and spring up on tracts which have been swept by desolating bush fires, and many seeds refuse to germinate until heated by fire or steeped in hot-water: the seeds of the Australian acacias (wattles), for instance, should always receive a steeping in hot-water before being sown. "H. E." writes as if there were a real distinction between plantains and bananas. We are not aware of any, although we have occasionally heard very large sized plantains grown in Ceylon called bananas. Here we speak of plantains: in America, and we believe in the West Indies, in Australia and most other parts of the world, "banana" is the term for the nutritious starchy and saccharine fruit, so valuable as an article of food to the inhabitants of the tropics.

Since writing the foregoing, we have referred to the "Treasury of Botany," from which we learn that botanists observe a slight distinction between the plantain and banana. The following contribution by Dr. Masters ("M. T. M.") is of general interest, apart from the question under notice:—

M. paradisiaca and *M. sapientum* are the botanical names by which the plantain and banana are respectively known. The latter has its stems marked with purple spots, and its fruits are shorter and rounder than those of the plantain, but otherwise the two plants are little different one from the other. They have been cultivated from the most remote times in tropical climates, in subtropical Asia, America, Africa, and the islands of the Atlantic and Pacific Oceans, for the sake of their fruits, which they produce in enormous quantities with very little attention. There are several varieties, the fruits of which differ in flavour, but all are more or less mawkish and viscid, at least in the ripe state, for the starch that abounds in the unripe fruit becomes converted, as it ripens, into mucilage and sugar. They are highly nutritious, and serve as the staple food of a large number of the human race. Though less nutritious than wheat or potatoes, yet the space occupied by their culture, and the care required, are so very much less, that Humboldt has calculated the produce of bananas compared to that of wheat as 133 to 1, and ta that of potatoes as 44 to 1.

Plantain meal is obtained by powdering the dried fruit; it is very nutritious, as it contains not only starch, but protein or flesh-forming material. The fruits of the plantain are stated by chemists to be most nearly allied in composition and nutritive value to the potato, and the plantain meal to rice. The natives of many parts of India live almost entirely on plantains, and the stems, laden with fruit, are made use of at wedding festivities, in token of plenty. Plantations of bananas or plantains are made by settlers to support their families, and the fruits are eaten raw, or cooked in various ways. The expressed juice is in some countries made into a fermented liquor, and the young shoots eaten as a vegetable.

The specific name, *paradisiaca*, was given under the supposition that the fruits of the plantain were the Forbidden Fruit of the Scripture, or the fruits called grapes that the spies brought to Moses from the promised land as evidence of its fertility; but it is hardly necessary to say that there is no foundation for such opinions.

When the stems are cut down, or decay after the formation of the fruit, new suckers are sent up from below, and these in the course of a few months produce fruit in their turn. Each bunch of fruit weighs from sixty to eighty pounds and upwards, even when ripened in hothouses in this country. The abundance and nutritive properties of the fruit are not the only qualities which give these plants their value. Their leaves serve as thatch for houses, and for other domestic purposes; and some parts are used medicinally in cases of dropsy, and as an external application to burns and ulcers.

The *Musas* are likewise remarkable for the quantity of fibrous tissue pervading their leafstalks, and which is capable of being employed for weaving purposes, for making paper, &c. One species, *M. textilis*, is especially valuable on this account. It furnishes what is known as Manilla hemp, the plant being cultivated in the Philippine Islands for the sake of its fibre, the finer kinds of which are woven into beautiful shawls, and the coarser employed in the manufacture of cordage for ships, &c. A very large supply of fibre, adapted for papermaking and other purposes, could be obtained at comparatively little cost from this and various species of plantain.

Several species are cultivated in hothouses in this country for their foliage or for their fruit. *M. chinensis*, also called *Cavendishii*, a dwarf species from China, produces fruit abundantly in our hothouses. *M. Ensete* is a native of Abyssinia, where it was discovered by the traveller Bruce. Its fruit is dry and inedible, containing a few large stony seeds; but the base of the flower-stalk is cooked and eaten by the natives. A plant of these species was for many years one of the chief ornaments in the palm-house at Kew, its leaves being upwards of twenty feet long, and traversed by a stout vivid red rib, while the trunk attained a circumference of nine feet in three years. It was remarked by Bruce that on ancient Egyptian sculptures representations of Isis with ears of corn, and the foliage of the banana occur, and sometimes carvings are met with showing the hippopotamus destroying the banana. Now the true banana is not a native of Egypt; hence Bruce surmised that the Abyssinian *Ensete* was intended. The hippopotamus typifies the Nile, the inundations of which have gone so far as to destroy not only the wheat, but also the *Ensete* which was to supply its place.—[M. T. M.]

THE ANALYSIS OF CINCHONA BARK.

Mr. A. C. Dixon is good enough to write in the interests of planters and others as follows:—"A paragraph in your paper on Saturday in regard to the

analysis of cinchona did not give books where much information could be got *re* analysis. It is very scanty in all you name. The best works are in German. The best English work on the subject has recently been published I send it to you perhaps you might like to reprint a portion for planters. See page 448 on the Determination of total alkaloids and separation of the same." The book in question is Vol. II. of "Commercial Organic Analysis" by Alfred H. Allen, F. I. C., F.C. S., published by Churchill this year. The important chapter to which Mr. Dixon refers is as follows :—

ASSAY OF CINCHONA BARKS.—The complete assay of the various species of cinchona bark, with the view of ascertaining the proportion of the different alkaloids contained in them, is a process at once important and difficult. A great many methods have been proposed, but very few can b trusted to yield accurate results when employed by chemists unused to them. Again, a process which is suitable when quinine is the chief alkaloid present becomes difficult of application when the cinchonine is in excess. Unfortunately, also, certain processes which are extensively employed by professed quinologists are kept strictly to themselves.

In choosing a process of assaying cinchona bark, due consideration should be given to the kind of information required. Thus, a pharmacist desiring to know the alkaloidal strength of his bark, will require a less accurate and elaborate process than a manufacturer buying bark for the extraction of quinine. Again, in some cases it is sufficient to determine the percentage of total alkaloids, while in others it is very important to ascertain the proportion of crystallized sulphate of quinine which the bark is capable of yielding. On this account, it is desirable to discuss the determination of the total alkaloids and of the actual quinine separately.

DETERMINATION OF THE TOTAL ALKALOIDS OF CINCHONA BARK.—1. The following process is that of De Vrij, with certain modifications suggested by Prescott and Muter. It is applicable to all varieties of bark. 20 grammes* of the finely powdered bark, weighed after drying at 100° C.,† is thoroughly mixed with 5 grammes of quicklime and 50 c.c.‡ of water. The mixture is then dried at a very gentle heat. When dry, it is transferred to a flask fitted with an inverted condenser, nd boiled with 200 c.c. of the strongest rectified spirit.§ The liquid is allowed to cool, and is then passed through a filter 6 inches in diameter, and the residue is again boiled with 100 c.c. of alcohol, and then washed twice with alcohol, using 50 c.c. each time. The filtrate is next rendered slightly acid by dilute sulphuric acid, and, after allowing any precipitate of calcium sulphate to subside, the liquid is passed through a very small filter, which is washed with a little alcohol. The filtrate is evaporated or distilled till the alcohol is expelled, cooled, and again passed through a small filter, the precipitate, consisting of quinovic acid and fatty matter, being washed with water slightly acidulated with sulphuric acid. The filtrate, which contains the alkaloids in the form of acid sulphates, is then concentrated to about 50 c.c. or less, and transferred to a separator of 100 to 150 c. c. capacity. Soda is next added in decided excess, and the liquid containing the separated alkaloids then shaken without delay with 30 to 40 c. c. of previously washed chloroform. After a few minutes' agitation, the liquid is left at rest till the chloroform has completely separated from the aqueous layer. The lower stratum is then tapped off, and the watery liquid agitated three times more with chloroform, using from 2 to 30 c. c. on each occasion. The mixed chloroformic solutions are then distilled to a small bulk, the residual liquid evaporated to dryness, and the residue dried in the water-oven till constant in weight. The amount so found represents the total alkaloids in the 20 grammes of the bark taken.

* A gramme=15·4328 grains; 28⅓ grammes go to an oz.—ED.

† 100° c.=212° F—ED.

‡ A centilitre (1-100th litre)=2 dr. 49 min.—about a small dessert-spoonful.—ED.

§ The spirit may be methylated, but should be previously dehydrated to about 93 per cent. by being kept in contact with freshly-ignited potassium carbonate. Soxheth's extracting apparatus, shown on page 127, might doubtless be advantageously employed for the alcoholic treatment described in the text.

Cinchonine and cinchonidine readily become anhydrous at 100°, and quinine may be trusted to do the same. Quinidine retains 2 aqua in thewater-oven, but the proportion in which this base occurs is too small appreciably to affect the accuracy of the assumption that the alkaloids are weighed in the anhydrous state. If preferred, however, the temperature may be raised 115°C.*

For the assay of *yellow* cinchona bark, ether may be substituted for the chloroform employed in the above process.

2. The foregoing method being thoroughly satisfactory for the extraction of the total alkaloids of cinchona bark, it is only necessary to describe in detail one other, which is that of Hager. The accuracy of the method has been confirmed by O. Medin.†

Ten grammes of the dried and finely-powdered bark are treated for a short time with 100 c.c. of water and 10 grammes of caustic potash solution of 1·35 specific gravity. The mixture is then heated and kept at the boiling point for a quarter of an hour. 15 grammes' weight of diluted sulphuric acid (sp. gr. 1·115) is next added, and the whole boiled for twenty minutes. After cooling, both liquid and residue are transferred to a measuring cylinder, and diluted with water till the whole has a volume of 110 c.c.‡ The liquid is then passed through a dry filter, and 60 c.c. of the filtrate (=6 grammes of bark] are mixed with 50 c.c. of a cold, saturated, aqueous solution of picric acid. After standing for a half-an-hour the precipitated picrates are filtered off, washed with a little cold water, dried at 100°, and weighed. The product contains 42·5 per cent. of its weight of alkaloids, calculated as quinine. A preferable plan is to suspend the washed precipitate in cold water, add excess of caustic soda, and agitate with chloroform. The chloroformic solution of the alkaloids is then treated as in process 1. The picric acid method of assaying cinchona barks is said to be accurate, easy, and expeditious.

Probably a very perfect and expeditious method of obtaining the total alkaloids from cinchona barks would be to extract the dried mixture of the powdered sample with lime, obtained as described in process 1, in a Soxheth's apparatus, with chloroform. Very little of the solvent would be required, and, by avoiding the evaporation of dilute alcoholic or aqueous solutions, there would be no danger of producing amorphous alkaloids.

SEPARATION OF THE ALKALOIDS OF CINCHONA BARKS.—The separation of the various alkaloids of cinchona bark is a far more difficult problem than the determination of the total amount present. In some cases it is sufficient to determine the proportion of crystallizable quinine, which may be effected as described on page 453, but in other cases it is necessary to determine also the cinchonine, cinchonidine, and occasionally the quinidine, quinamine, and amorphous alkaloids. Such an analysis is very difficult, and its accurate performance presents special obstacles to an inexperienced analyst. For the separation of quinine from the admixed alkaloids, ether is usually employed, but it must be remembered that the separation effected by this solvent is not an absolute one, all the free cinchona bases being more or less soluble in ether, especially in the presence of quinine. The anhydrous sulphates of quinine and cinchonidine are almost insoluble in chloro-

* With a few modifications of minor importance, the method described in the text is that used by our best quinologists. Dr. Paul prefers to work on a very large quantity of the bark (about 2 lb.). Having treated with lime, alcohol, and acid in the manner described in the test, he precipitates the aqueous solution of the sulphates with soda, filters, washes slightly, dissolves the precipitate in acetic acid, and filters from any undissolved colouring matter. The filtrate is divided into two equal parts A and B. A is precipitated by ammonia, filtered, and the filtrate shaken with chloroform, which is then used to dissolve off the alkaloids from the filter. The solution is evaporated, and the total alkaloids weighed, after drying at 115eC. B is treated in a manner similar to A, but the chloroform is replaced by ether. The alkaloid thus dissolved is called "quinine," the difference between that and the total alkaloids being the "other alkaloids."

† *Zeitsch. Anal. Chem.* viii. 477; and ix. 447.

‡ This is allowing 100 c.c. for the liquid, and 10 c.c. for the bulk of the residual woody fibre, &c.

form free from alcohol (see page 430) but in presence of sulphate of cinchonine or quinidine, sensible quantities pass into solution. Crystallization of the quinine sulphate from water affords a simple and fairly accurate mode of separation, which has the advantage that is is similar to the process employed by the manufacturer.

The tabulated scheme for the separation of the principal cinchona bases on next page is founded on a method described by De Vrij.* The process requires a considerable weight of alkaloids, and does not yield strictly accurate results. Traces of quinidine and cinchonidine are dissolved by the ether, and are only recovered on treatment of the amorphous alkaloids with a limited quantity of ether as directed. In presence of much quinine the solubility of cinchonidine in ether is notably increased. The best part of the process is the accurate estimation of the crystallizable quinine, and this determination may be still further improved by substituting iodosulphate of quinoidine for the tincture of iodine, as described on page 421; † but this mode of operating sacrifices the possibility of investigating the nature of the amorphous alkaloids.

A weight of not less than 2, and preferably 5, grammes of the mixed alkaloids in a free state is finely powdered, and treated in a closed tube with ten times its weight of ether (free from alcohol). The mixture is well shaken and left at rest for twelve hours, when it is filtered, and the residue washed with a small quantity of ether.

A. The residue is dried and weighed. It may contain *cinchonine, cinchonidine* and *quinidine*. It is dissolved in a slight excess of dilute hydrochloric acid, and the solution rendered neutral by cautious addition of soda. The cinchonidine is then precipitated as tartrate, the quinidine as hydriodide, and the cinchonine as hydrate, the operations being conducted exactly as described on page 454, with the exception that quinine and amorphous alkaloids having been previously removed, the processes and calculations necessitated by their presence may be omitted.

B. The ethereal solution is evaporated to dryness, and the residue weighed. It consists of *quinine, amorphous alkaloids*, and *quinamine*, with traces of *quinidine* and *cinchonidine*. It is dissolved in 10 parts of proof spirit, acidulated with 1-20th of sulphuric acid. To this solution an alcoholic solution of iodine is gradually added as long as a precipitate is produced. Excess of iodine must be carefully avoided. In presence of much quinine, a black precipitate of herepathite is immediately produced, but, if the quantity is small, some time is required for its appearance. In such a case only a small quantity of iodine solution must be added, and the liquid well stirred, and left twelve hours. The precipitate is filtered off, and washed with strong alcohol.

The precipitate consists of herepathite. It is dried at 100° C., weighed. The weight, multiplied by ·55055, gives the quantity of *quinine* in the mixed alkaloids operated upon. The precipitate may also be treated as suggested in the note on page 451.

The solution is treated with sulphurous acid till colourless, and then carefully neutralized with caustic soda. The alcohol is evaporated off, and the liquid treated with excess of soda or ammonia, and agitated with chloroform. The residue left on evaporating the chloroform consists of *amorphous alkaloids*, with traces of *quinidine*. The two latter will remain undissolved on treatment with a limited quantity of ether, and the amorphous alkaloids may be distinguished as described on page 444.

In some cases it is desirable to separate the quinine in the actual form of crystallised sulphate, this being regarded by many as the best proof of the proportion obtainable by the manufacturer. The following method described by Muter is the most accurate mode of proceeding:—

Treat the total alkaloids or the ether-residue from 20 grammes of bark with warm distilled water slightly acidulated with dilute sulphuric acid, till the mixture is perceptibly acid. Add water to make 70 c.c. for each 1 gramme of alkaloids taken, and then very dilute soda with constant stirring till the liquid is exactly neutral, with a faint tendency to acidity. Digest the liquid at 85° C. for five minutes; then cool, and leave at 15° C. for one hour. Filter the liquid through a small double filter (2¾ inches diameter), the two filters being previously trimmed to equal weight, and receive the filtrate in a graduated cylinder. Wash carefully with water at 15° C. till the filtrate and washings measure 90 c.c. for each 1 gramme of the mixed alkaloids. The filter and contents are now completely dried at 100° C., and weighed, the second filter being used as a counterpoise. To the weight in grammes add ·000817 gramme for each c.c. of filtrate and washings. The sum divided by 0·855 gives the corresponding amount of crystallised sulphate, and this number multiplied by 5 gives the crystallised quinine sulphate obtainable from 100 grammes of dried bark.

The quinine sulphate so obtained is apt to contain cinchonidine sulphate (see page 435).

The foregoing method may be applied with advantage to the residue obtained by evaporating to dryness the ethereal solution B. of De Vrij's process (page 452), and for many practical purposes is even preferable to precipitation as herepathite. The remaining alkaloids may be recovered from the filtrate from the quinine sulphate by concentrating the liquid somewhat, adding soda in excess, and agitating with chloroform. On evaporating the chloroform the bases will be obtained in a solid state, and may be separated in the following manner. The method may also be applied to the total mixed alkaloids extracted from a sample of bark, in which case it may be carried on simultaneously with the treatment for crystallised quinine sulphate described above.

The mixed alkaloids extracted from the bark or the filtrate from quinine sulphate by treatment with soda and chloroform, or the residual alkaloids left on treating the total alkaloids with ether (see page 452), are dissolved in strong alcohol. The solution is rendered faintly acid by hydrochloric acid, and evaporated to dryness at 100° C. The residue is dissolved in the least possible bulk of water at 40° C., and the trace of free acid neutralised by soda. A saturated solution of Rochelle salt is next added in excess, the liquid cooled to 15° C., and repeatedly stirred during one hour. Crystalline streaks in the track of the glass rod consist of tartrate of cinchonidine (or quinine). The precipitate is collected on a double tared filter, and washed cautiously with cold water, the filtrate and washings being collected in a graduated cylinder.

The precipitate is dried at 100° to 105° C. and weighed, the outer filter being used as a counterpoise. The amount found is corrected by adding ·00083 gramme for each 1 c.c. measured by the filtrate and wash-water. The sum multiplied by ·804 gives the weight of *cinchonidine*. If quinine has not previously been separated, the amount of crystallised sulphate found must be multiplied by ·915, and the product substracted from the weight of the tartrate before calculating it to cinchonidine.

A. The filtrate is concentrated to its original bulk, cooled, a drop of dilute acetic acid added, and then excess of a saturated solution of potassium iodide (free from any alkaline reaction). The liquid is left for two hour at 15° C., being frequently stirred. Any streaks in the track of the glass rod are produced by quinidine hydriodide. The liquid is filtered on a double counterpoised filter, and the precipitate cautiously washed with cold water.

The precipitate is dried at 100° and weighed. Its weight is corrected by the addition of ·00077 gramme for each 1 c.c. of filtrate and washings (B). The sum, multiplied by ·7168, gives the *quinidine*.

B, filtrate is measured and made distinct by alkaline with caustic soda. The precipitated *cinchonine* is filtered off, washed, dried, and weighed, or else extracted by agitation with chloroform. The weight found is corrected by deducting .00052 for each 1 c.c. measured by filtrate A., and ·00076 for each c.c. of filtrate B. Any *amorphous alkaloid* may be dissolved out by spirit of ·94 sp. gravity.

The foregoing process, with experience, gives very good results, the sum of the separated alkaloids frequently amounting to 99 per cent of the mixed bases operated on. It is well suited for Indian barks. The most defective part of the process is the separation of the cinchonine from the amorphous bases by dilute spirit. A cautious employment of ether is, perhaps, preferable. If the process of

* *Pharm. Journ.* [3], ii. 612.

† If desired, the herepathite may be converted into crystallized quinine sulphate by heating it with alcohol and sulphurous acid till colourless, and then neutralizing with soda and proceeding as described on page 453.

eparation be conducted simultaneously with the determination of the crystallized quinine sulphate in another portion, the whole analysis can be completed in about six hours.

The mixed alkaloids of yellow cinchona bark consist almost wholly of quinine, and hence the portion soluble in ether represents the whole useful constituents of the bark. Pale and red barks, on the other hand, contain a considerable proportion of alkaloids insoluble or sparingly soluble in ether. Hence the use of chloroform in the general process for assaying cinchona barks (see page 448).

In some cases the alkaloids soluble in ether are contaminated to a considerable extent with colouring matter. In this event, the following is a good method of obta-in ing colourless quinine sulphate:—The ether-residue is dried thoroughly and weighed. It is then dissolved in 30 c.c. of absolute alcohol, and decinormal sulphuric acid cautiously added from a burette, using litmus paper as an indicator, till the liquid is neutral or *very* faintly acid. The measure of acid used is noted. Each c.c. is equivalent to ·324 grammes of anhydrous alkaloids. The liquid is next evaporated nearly to dryness, and a measure of decinormal sulphuric acid added equal to that previously required for neutralization. 30 c c. of hot water are added, and the liquid boiled till complete solution results. Purified animal charcoal (prepared as described on page 227) is added, in quantity equal to the weight of the ether-residue. Heat the liquid on the water-bath for 20 minutes, filter, and wash the residue twice with boiling water acidulated with sulphuric acid. The filtrate is brought to a concentration of 70 c.c. for each 1 gramme of ether-residue taken, and then cautiously neutralized with caustic soda, and further treated as decribed on page 453.

Special processes for separating certain of the cinchona bases will be found on pages 435, 441, and 445, as also methods for testing the purity of the various commercial salts of the alkaloids.

Obviously every analyst of cinchona bark or other substances ought to possess Mr. Allen's very full and able work.

THE CULTIVATION OF CINCHONA IN CEYLON.

We are indebted to the courtesy of Dr. Trimen, the Director of the Royal Botanic Gardens in Ceylon, for a copy of his report on the work carried out under his guidance in the gardens during the past year, and are thus enabled to place before our readers some interesting information as to the progress of the attempts to cultivate in Ceylon various economic and useful plants, among which cinchonas and rubber-yielding plants are, perhaps, the most important at the present time. As regards the cinchonas, it may be mentioned that during the year 1880 a very great impulse was given to their cultivation in Ceylon, and very sanguine anticipations were entertained as to the probable results of this enterprze. The varieties grown were principally *C. officinalis* and *C. succirubra*. The climatic conditions of the higher elevations in Ceylon are remarkably suitable for the growth of the former, but at heights below 4,500 feet it appears more desirable to grow other varieties. Dr. Trimen satisfied himself last year that the more valuable *C. Ledgeriana*, though less abundant than the sorts above-mentioned, was nevertheless represented by a considerable number of trees scattered over several estates in the island, these having been raised from seed obtained either from the gardens of the Dutch Government in Java, or from Darjeeling or the Nilgiris, but in all cases being descendants of the seed originally brought over by Mr. Ledger. In speaking of the cultivation of this most valuable variety of cinchona, Dr. Trimen took occasion to impress upon the attention of owners of these trees the extreme importance of minimizing the chances of their being crossed by the pollen of other and inferior kinds. He recommended that, if any of these were in the immediate neighbourhood, they should be destroyed, and that in selecting seed trees no pains should be spared in ascertaining from analyses by a competent chemist which were most suitable for the purpose, all those which did not give good results on analysis of the bark being ruthlessly destroyed. It is only in this way that it will be possible after a few years to obtain seed that will come true, and growers may judge of the desirability of this course being adopted by them from the probability that before long it will be only the best kinds of bark yielding a large amount of quinine that will secure good prices.

In the report for the year 1881, which has just come to hand, Dr. Trimen again refers to the supreme importance of selection based on analysis in the scientific cultivation of *C. Ledgeriana*, and he mentions that the observations made on this point in his previous report have been supported by further experience. As a general rule the botanical characteristics were found to tally with the bark value, so that selection intelligently made on that basis was usually justified by subsequent analysis; but such very distinct exceptions to this general rule were occasionally met with as to force one to the conviction that the production of alkaloids must be largely personal, so to speak, to the particular tree, apart from its inherited external characters. For this reason, therefore, Dr. Trimen considers that analysis must still be regarded as the only certain guide in the judicious selection of trees for the cultivation of *C. Ledgeriana*.

The simple process of grafting on *succirubra* has been found in a large proportion of cases both easy and successful in the propagation of *C. Ledgeriana*, and it is considered that this or some similar process must become the general practice in the cultivation of specially valuable trees on the principles advocated.

Much attention has lately been directed to the large and usually readily distinguished trees found scattered over estates in Ceylon, and variously known as "hybrid," "lanosa," or "large-leaved Condaminea." These trees were sent out from the Hakgala nurseries in past years, usually as *succirubra*, but sometimes as *officinalis*, and they are identical with the "magnifolia," "pubescens," "robusta," etc., of the Nilgiri Government plantations, from whence they were doubtless originally received. They were first noticed there by Mr. McIvor, and considered at one time by him to have originated by the crossing of *succirubra* and *officinalis*. The same view was also taken in Ceylon, but Colonel Beddome, after examining these plantations, has come to the conclusion that the trees in question are not of hybrid origin, but from a well-marked and distinct species. Dr. Trimen does not share this view, which was largely based upon the positive statement of Mr. Cross that the plant is the same as that yielding the "Pata de Gallinazo" bark of Chimborazo, which he collected there when with Dr. Spruce, and he considers that there are great difficulties in accepting this story. Thus, for instance, a comparison of the Nilgiri plant with Spruce's original specimens at Kew does not lend it any support whatever. On the contrary, the two kinds seem to be quite distinct in several respects, and M. Triana, one of the most careful and accurate botanists who has made cinchonas a special study, has referred Spruce's specimens to *C. erythrantha*, Pav., which is considered to be a variety of *C. pubescens*, Vahl. According to Dr. Trimen, the view which is on the whole most in accordance with the facts is that the plant is a hybrid which has acquired some permanence and stability, though he is not in a position to speak decisively as to the amount of permanence from seed. Colonel Beddome maintains that it comes as true to type as any other species, while the majority of observers in Ceylon state positively that a large proportion turn out to be *succirubra* and *officinalis*. In Sikkim, also, where this kind, originally from Ceylon, is called "ignota," fully half the seedlings are said to come up *officinalis*. Dr.

Trimen proposes that the distinctive name *robusta* should be applied to this cinchona, as it is the only one that is not preoccupied or otherwise unavailable. He also thinks that those who can do so should propagate it by cuttings from trees ascertained by analysis to be good; but the more rapid increase by seed need not be neglected, as the young plants showing reversion could be easily removed.—*Pharmaceutical Journal.*

GOVERNMENT CINCHONA PLANTATIONS.

The following summary from the *Madras Times* shews that as a mere money speculation, the cinchona enterprize of the Madras Governmemt has been a success, while the gain to humanity has been incalculable. No doubt the reason why barked trees coppice best is that the shock to the system of the tree increases the tendency to the preservation of life by sending out shoots from the lower portion of the stem :—

"We gather the following particulars from the last Administration Report on these plantations submitted to Government by Colonel Jago. In accordance with the wishes of the Secretary of State, the supervision of the cinchona plantations hitherto entrusted to the Commissioner (now Collector) of the Nilgiris was transferred during the latter part of the year to the Conservator of Forests, and the Local Forest Officers assumed charge of them on the 1st February 1881. Deducting casualties, and adding plants put out, the total number of trees in the plantations had risen from 569,031 in 1878 to 666,815 on the 31st March 1881. During the year 1,140,209 plants, seedlings and cuttings were raised, of which 843,484 were issued to the public. Three plants of the Santa Fé and six of the Carthagena varieties were brought by Mr. Cross in October 1880. The three plants of the former variety were taken care of by Mr. Cross himself who had at the close of the year six established. The six Carthagena plants were handed over to the Superintendent of the Botanical Gardens, Ootacamund. Though five of these plants died, a portion of the plants was saved for cuttings, five of which had rooted on the last day of the year. The yield of the year was 243,896lb of dry bark against 179,299lb in the previous year. The sale of bark realized the following amounts during the year :—

	R.	A.	P.
Value of bark sent home	405,860	9	4
Value of bark supplied to Bombay Medical Department.	2,397	15	4
Value of bark supplied to Private Parties.	12,827	4	4

"A further sum of R13,175-4-8 was received from the sale proceeds of plants and seed, the total receipt being R434,261-1-8 against an expenditure of R96,105-0-7. It is observed that coppices from bark trees have been found to grow much better than those from unbarked trees. Manuring operations were about to be increased, and the conservancy of the plantations was well attended to. The financial results from the commencement of the cinchona enterprize up to the end of 1880-81 show a net profit of R58,252-6-9 at the close of that year."

SHADE FOR TEA.

The subject of shade for tea is one which does not obtain that attention which it deserves. For a long period, all shade has been removed from the tea gardens, and a new clearing for tea was perfectly denuded of trees. By and by it was found that, while the great heat of summer certainly vitalized the bushes, and, as it were, forced on the flushes, it likewise led to intense evaporation, which speedily left the plant panting for moisture. In the North-west, moderate shade tended to increase production, by hindering evaporation, and leaving more moisture in the soil. Three things have been found essential; the shade must not be too dense, nor the trees too close together. By planting trees widely, the sun got at every bush for a short period, while for the bulk of the day the bushes were in shade. The shade should be so open that the sunlight should be able to find its way through, here and there, to the plants, and this can be managed by judicious tree pruning, and by planting the proper class of tree. In the second place the tree ought not to be a surface feeder. Such trees withdraw the nourishment intended for the tea bushes, and *third*, the trees should be those shedding their leaves liberally. This for purposes of returning to the soil much which may have been removed by the necessities of tree life. Each district must select its own trees for this purpose. In the North-west the most suitable are the toon (*Cedrela toona*) the *tallow* tree (*Stillingia sebifera*), and the sissoo (*Dalbergia sissoo*). The toon and sisoo trees produce valuable timber, and after 25 years the trees may be thinned out and sold, their places being supplied by seedlings of other varieties.—*Indigo Planters' Gazette.*

A TRIP TO MALACCA: TAPIOCA CULTIVATION.

(From the *Gardeners' Chronicle.*)

As tapioca is now one of the principal articles of export from the Straits Settlements a few notes made during a flying visit I recently paid to Malacca regarding the mode of cultivation and the primitive and modern modes of manufacture there employed may not be uninteresting to some of your readers. During a six years' residence in the Straits I was never fortunate enough to have sufficient time to spare in Malacca to go far beyond the limits of the town; yet when one reflects on what Griffith, Thomas Lobb, Maingay, and others have unearthed from its jungles it has become to the botanist and naturalist the most interesting part of the Straits Settlements, and, while driving along its country roads or traversing its jungle paths and reflecting on the work done by those lovers of nature, one feels that he is on classic ground so far as botany is concerned.

It was, therefore, with no little satisfaction that I accepted an invitation from Mr. J. M. Lyon, who is the head of an engineering firm in Singapore that has acquired considerable local renown for its inventions for manufacturing tapioca, to accompany him on a short trip to Malacca before leaving for "the land of the white elephant."

Leaving Singapore at 4 p.m. on September 14th by the steamship "Mayflower"—which, by-the-bye, is not the same craft which conveyed the "Pilgrim Fathers" from the shores of Old England "converted" —we arrived in Malacca (locally known as "Sleepy Hollow") at 9 a.m. next morning, and at once called on some of the principal tapioca planters.

Before starting for the plantations we were treated to a surfeit of Malacca fruits, which at the time of our visit were abundant, including delicious Dukus (Lansium domesticum), the Tampui (Hedycarpus malayanus), which, I think, is much to be preferred to the Mangosteen, of which, of course, we saw plenty, and splendid Chikos (Sapota Achras), which, although is not an indigenous fruit, thrives and fruits to perfection in Malacca.

Before noon, however, in company with two of the most extensive and energetic planters in the colony, Mr. Chca Hooo Bong and Mr. Koh Hoon Boh, we were *en route* to their plantations.

To the estate of the former gentleman, which is about 10 miles from Malacca, the drive was very enjoyable, the sides of the road for some distance being mostly overshadowed with Coconuts, while under-

neath the Rambeh trees (Pierardia dulcis) were loaded with long hanging racemes of fruit, while large clumps of Salak (Zalacca edulis), Licualas, Bauhinias, Poinciana pulcherrima, Ixoras, &c., served to diversify the vegetation, Some fine native grown coffee was passed, laden with ripe fruit, and further on a thriving nutmeg plantation was passed through. Further on, where the jungle road begins, there was little to interest—Rhodomyrtus, Grewias, Mussænda and Melastoma forming the larger part of the vegetation.

The mode of cultivating tapioca in the Straits varies but little on different estates, whether owned by Europeans or Chinese. If jungle composed of large trees is to be cleared the trees are cut down at some height from the ground, the stumps remaining in the ground and the whole set on fire, the charred remains of the trees being generally allowed to lie where they fall until the first crop is being cleared off, when they are utilized for fuel. After the ground has been dug over and the soil put into a friable condition the cuttings of tapioca are planted in rows from 3 to 4 feet apart and about 9 inches or a foot in the rows. The cuttings are lengths about a foot long of the stem of the matured plant. These root easily, and in less than two months the ground is covered with a carpet of green almost a foot high. From this time to the time the crop is lifted, beyond weeding and slightly banking-up, nothing is done to the crop, although on some estates the tall stems are sometimes cut down to about 4 feet from the ground, which must evidently keep the plants in a growing state, and prevent the proper storage of starch. On some estates I have known the crop lifted nine months after planting, with good results; but the Chinese planters in Malacca usually keep the roots in the ground sixteen or even eighteen months. Perhaps each has its advantages, but it has struck me that tubers kept in the ground over a year develop a large amount of woody fibre without increasing the quantity of starch, which is evidently a disadvantage to the machinery. The general mode of lifting the crop is to cut off a certain portion of the tops, and pull up the tubers, the broken pieces being dug out afterwards. Of course, on land that has previously carried a tapioca crop, manure should be used which by some planters is applied previous to planting, and by others after the young plants have started into growth. In Malacca, however, cow-shed refuse is a scarce article, and the cost of carriage would be considerable where estates are distant from the base of supply and roads in many instances steep and bad.

On one estate in Singapore under European management a green crop is grown with the tapioca, consisting principally of Arachis hypogæa, various Crotalarias, principally C. striata, &c., which is dug in with lime, &c., while green, for the next crop, but the plan does not appear to find acceptance with other planters. The root of the tapioca it is hardly necessary to describe here, but I may state that while in Malacca I saw some specimens over 2 feet long, and weighing between 6 and 7 lb. The roots being laid in heaps are carted to the manufactory, and the sticks laid in stacks for supplying cuttings for the next crop.

The estate first visited in Malacca was Bukit Bruang (literally Bear Hill), and here we found J. M. Lyon & Co.'s patent machinery in full working order.

Of course steam is the motive power: in fact the most primitive styles of preparation seem unable to do without this, as I will show later on. The roots, being first divested of their woody tops, are thrown into a large revolving drum, in which pipes are so arranged that constant jets of water play on them as they are turned over and over, and gradually they reach the farther end of the drum perfectly clean, and empty themselves into a rasping machine, whence they emerge in the form of a fine pulp, which is thrown direct from the rasper into another cylinder covered either with stout muslin or brass-wire gauze, through the sides of which jets of water are continually passing. By this process the starch is separated from the pulp, the starch passing through the muslin or gauze into a tank beneath, where further supplies of water send it off through gutters to vats prepared for its reception, while the pulp is discharged from the drum into baskets and thrown into heaps either for cattle feeding or manure, for either of which I imagine it is little suited.

After the starch in the vats has been allowed to subside the water is gradually drawn off, fresh water supplied, the whole stirred up and again allowed to subside, and the water again drawn off. The treatment of the starch in this stage depends on the purity of the water used—as, unless the tapioca when prepared is of the purest whiteness, it can hardly be given away. Hence, one of the principal points to be attended to is the supply of clean water in abundance. After the starch has become sufficiently pure it is allowed to dry in the vats, whence it is cut out in cakes and is then ready for the last stage of preparation. If tapioca flour is required it is placed first on racks to dry, then on large, almost flat tin sheets which form the top of a brick flue where an extremely gentle fire is kept up.

If flake tapioca is requisite it is submitted to rather stronger heat in concave pans at first, whence it is removed to the previously mentioned sheets and kept turned over with wooden rakes, &c., until it assumes the flake-like form so familiar to consumers in Europe. The flakes are then sifted, to separate the various sizes, and the prepared tapioca is ready for placing in the bags for shipment.

After a liberal tiffin, for which we were indebted to the proprietor of the estate, Mr. Chea Hoon Bong, we started for an estate some 8 miles farther on belonging to Mr. Koh Hoon Boh (the name of which I have unfortunately forgotten, and as I have mislaid all my notes about our first day's trip I am obliged to fall back on memory for particulars).

Now commenced the real business of the day. The road from Bukit Bruang to this estate is in some places so steep and bad that only light traps are available, hence it became necessary for either my companion or myself to drive while our Chinese hosts came on behind in another carriage. As it soon became apparent that unless I drove we should remain behind at Bukit Bruang, I was compelled reluctantly to take the ribbons, more especially as I found that our united weight amounted to close on 32 stone, to say nothing of the syce, who would be compelled to hang on behind somehow. The road did not belie our expectations, as it lies mostly through tapioca estates, and cut up by constant bullock-cart traffic, with the end of charred trees projecting on one side, and living ones with enormous buttresses jutting out on the other, combined with stiff inclines and declines and sharp corners, so that it was out of the question altogether to think of looking at the vegetation as we passed.

Arrived at our destination, we found the machinery in splendid order, in three hours putting through 120 piculs (a picul is 133 lb.) of roots, one-fifth of which would be tapioca eventually. On this estate about 20,000 acres are under cultivation. Reaching Bukit Bruang on the return journey safely, we changed vehicles, and arrived at Malacca at 8. P.M., visiting a very flourishing nutmeg plantation belonging to Mr. Koh Hoon Boh on the way, and leaving our hospitable friends at their estates.

Arrived in Malacca, we found ourselves pretty well tired, but our labours were by no means yet at an end. My companion had declined several country invit-

ations to dinner and a bed for each of us, as he had always been accustomed to put up at the house of a planting friend in Malacca, and depended on being able to do the same this time; consequently, on arriving at the entrance, we got our traps out and discharged the carriage. Judge of our surprize when, after sitting down a little while, we were told that Mr. —— was away at the plantation.

Calling a carriage, we started to find somewhere to put up at, as Malacca possesses no boarding-house or hotel, and, as there is nothing to do in Malacca after 6 p. m., residents retire early; so on driving to one house after another we found them shut up for the night. Driving to the residences of some bachelor friends we were informed by the servants that "master had gone for a walk, and the time of his return was uncertain." This caused us to look rather stupidly at each other, and, after a drive all round the town, I proposed that we should put up in the carriage for the night, my companion proposing that we should go back and take possession of the house of one of our absent friends. This we acted on, and succeeded admirably, being warmly welcomed by our host after the first surprize of finding "men in possession."

I have related this incident rather in detail as it will help to give some idea of the state of civilization at which Malacca has arrived, and as a "word in season" to travellers who think of visiting Malacca to make sure of a bed before arranging to stay ashore a night there.

Next morning at 6 o'clock we were *en route* to another estate, belonging to Mr. Koh Hoon Boh, at Matchap, about 18 miles distant. The first ten miles is along the public road, along some parts of which in wet situations are large indigenous plantations of the Glam (Melalenca leucodendron), the bark of which is used by Malays for caulking their boats. In all directions we saw the natives busy planting the rice fields.

On leaving the public road, however, our troubles began; to drive over the road we did the day before was a delight compared with the one it now fell to our lot to drive over, and it was with no little satisfaction that I gave up the reins at Matchap to the syce, after his informing me when within 50 yards of the house that I had 2 miles more to drive. Here we found the primitive style at work. The roots are first half-peeled with knives, in which operation a large part of the root is cut off, then thrown into a tank of water when they are washed by the Chinese treading on them; thence they are lifted in baskets, to the rasping machine, and worked by a traction engine, built in the brickwork, and regulated by hand. The pulp falls from the rasper into baskets, which are carried about 20 yards, and the contents emptied on muslin covers of concave wickerwork baskets, above which a wooden water gutter is placed, the supply of water being regulated by plugs over the baskets. Here the Chinamen separate the starch by arranging a constant fall of water on the muslin, and keeping the mass well stirred with their hands until they think they have extracted all the starch, when they throw the refuse pulp away, and receive a fresh supply from the rasper, the water with which they wash the pulp serving to convey the starch to vats prepared for it. Of course the starch prepared in this manner requires more washing than that prepared by the machinery I have described, and I venture to think that consumers in England would prefer tapioca made by machinery, when it need never be handled, to that which is carried about so much amongst decaying vegetable matter and mud, as that hand-prepared usually is Here the starch is backed by fire passing beneath a tile covered flue on which it is placed. Pearl tapioca is manufactured here as follows:—A cloth is attached like a hammock to the beams and kept open by cross sticks. A man at each end alternately jerks the cloth to and fro, the slightly warmed starch under this treatment soon forming small. completely spherical balls, which are afterwards baked on a tile-covered flue.

The number of coolies about here was surprizing, and it is hardly necessary to say that only about 30 piculs of tapioca are produced per diem; in fact, Mr. Koho Hoon Boh is so thoroughly convinced of the superiority of manufacture combined with economy of the preparation by machinery, after comparing the cost at his estate, which we visited the day before, with the cost of hand preparation, as at Matchap, that he ordered a machine to be erected at once.

After tiffin we returned to Malacca, where we were lodged and fed, in first-rate style, our host being Mr. Chea Hoon Bong, whose name is well known throughout the Straits (and beyond) as one of the most liberal-minded and hospitable Chinese gentleman in the colony. The next day we parted from our hospitable friends of Singapore per steamer "Biliton," arriving on Sunday morning loaded with presents of fruit for ourselves and Singapore friends. Thus ended what is probably the last of my trips in the Malay peninsula, and certainly, thanks to my companion and our Chinese hosts, the most enjoyable one.

Can you or any of your readers give me any information as to the probable date of the introduction of tapioca into the Straits, or by what nation it was first brought to the East? I have not Crauford's *Descriptive Dictionary of the Indian Islands* to refer to but so far as I recollect he does not mention Manihot utilissima.

TRAVELLER.

THE NORTHERN TERRITORY OF AUSTRALIA.

[*S. A. Register's* Special Reporter.]

We were disappointed this morning. The latest recollections of the most sleepless of the party on Friday night were of rain pouring down as rain pours only in the tropics, and the prophecy was a flood today. But this morning when we left the ramshackle public house at Rum Jungle the sun was frowning witheringly upon us as though he intended to grill us offhand. The profuse jungle vegetation, rain-sprinkled, glittered like diamond rests; a select few of the comparative scarcity of birds—the jungle pheasant. the pigeon, the bower bird, the cockatoo, a sort of magpie, and others—piped out cheerily, those that could pipe; and gaudy butterflies—bright-yellow, and mauve-and-black, and one like an animated pansy, and a good pansy at that—fluttered gaily about atop the long intensely white seeding grass. And nature-lovers in the party were moved to music, and for once the prospect was that the trip would be a pleasure excursion.

Just behind the starting-point the telegraph poles begin to alternate—wood and iron—the intention being to make them all of metal eventually. They are burnt down now very often in the dry season, when the natives and the teamsters periodically fire the grass to secure a succulent growt immediately after the late rains. The soil for some distance beyond Rum Jungle is a rich brown loam, sprinkled with ironstone gravel in places—soil similar to that on McKinnon & Poett's plantation, three miles due west. The country is beautifully fertile and undulating, and there are some pretty peeps of scenery, the grass tall but less rank and more succulent; the trees stringybark, ironbark, white gum, and other kinds of eucalypti, as well as the screw palm, all twined round with different members of the convolvulus family. All the way along the road—and also as far as I could cross it while the other horses were perforce going along at a walk—the country is of the sort which would

make the fortune of a stockowner holding stock in it. It is grandly watered and grassed, and, of course is thickly dotted with anthills

This holds good more particularly with regard to the land north of Banyan Creek—called Banyan, I presume, because a peculiar far-spreading sort of fir-tree* grows there. Beyond we had an experience of the difficulties of vehicular traffic on the road. Half a dozen Chinamen, with five horses in a small dray, were struggling to extricate their property from the boggy road—a light stiff clay. They had only about eight hundred weight of rice, and they had been six days coming thirty-six miles from Southport. When the bog ceases the country becomes rugged and stony; less useful for patronage or tillage, and more valuable mineralogically. Several quartz-reefs crop up and there are ironstone and greenstone in plenty.

The most striking upland is Paqualin's Hump—two miles from Stapleton. On it good iron ore has been got, and from its crest you see one of the best views along the whole road. Surrounding hills form an almost perfect amphitheatre, and in the perspective are other elevations rising higher and higher till the last bounds the horizon. The descent of the Hump is long, stony, and winding. Just below its foot is a somewhat pretentious Chinese gardeo, in which are grown principally the peanut, from which the Chinamen have begun to manufacture oil; the sweet potato, which has been grown luxuriously after early failures through ignorance of the proper season in which to plant it; and Chinese beans. The Chinamen—gathered in a body—did their *devoirs* to the party.

Then you come to Stapleton Creek—named after poor Stapleton, who was killed by the blacks at one of the telegraph stations—which sometimes foams down more than a quarter of a mile wide, but now rippled over an rea of only a few yards in width. There is a ford which seems to have done much service. The grass all round for some distance has been eaten down and former rankness has become toothsome herbage. There are high-towering hills round the incipient township of Stapleton, and on the creek's banks grow, besides bright hibiscus, numerous screw-palm and a thick grove of a tall bamboo, which Professor Tate proclaims new to science—a bamboo which flowers periodically on a high stalk, but is not in bloom now.

"A PERFECT FOREST OF CINCHONA TREES FIVE YEARS OLD."

The description which "E. A. C." is good enough to send us of the successful clearing of Crown Bark trees on the upper portion of Loinoru, Bogawantalawa, will be read with general interest. The all-important point is the age of the trees, for clearings of the same variety, beautifully grown and regular and apparently as prosperous as could be desired, have not been uncommon in other districts up to two and even three years of age. Then the fatal canker appeared and one after another the trees died out until all were practically cleared off. If the Loinoru trees have lived over five years without any appreciable mortality, the case is decidedly exceptional and well worthy of the fullest investigation. We would recommend therefore that the Dikoya Association in place of calling for a prize essay, expend their money in getting a report from a competent Committee on the circumstances connected with the clearing, the character of soil and climate, the seed or plants used, the mode of planting, &c. "E. A. C." refers in general terms to the comparatively light rainfall and free soil with which the extreme corner of Bogawantalawa is favoured; but a more particular report ought to be of value. Free soil and a medium or light rainfall are not unknown in other districts where nevertheless clearings of the officinalis' species have, in the face of much care and outlay, proved comparative failures. The District Association with its energetic Secretary ought to cause an enquiry and report to be made *pro bono publico*.

*Fig-tree.—ED.

THE *TROPICAL AGRICULTURIST.*

(Reviewed by a competent authority.)

POSSIBLE SPORTING OF COFFEE AND CINCHONA.

The 1st volume of the *T. A.* has recently been completed by the issue of the June number with its most useful index. New products are discussed here and there in the journal and are steadily making their way to the front, especially cocoa. Tea, coffee and cinchona are all well represented by various articles treating of their cultivation, curing, &c. A large amount of correspondence has taken place about cinchonas *re* hybrids. The subject of hybridity is very easily understood. The term *cross* had better be dispensed with, as it is rather a popular than a strictly scientific term. Plants are divided into natural families and these families into general species and varieties. Now, it is a well-known fact that in the vegetable kingdom genera near akin, *i.e.* of the same natural order, may become fertilized the one by the other. Such a thing is of rare occurrence, but it has happened in the genus *Pyrus* with genus *Crataegus*, both belonging to the natural order Rosaceæ. The resultant plant is termed a *genus hybrid*, also called a *bigener*. Cinchona and coffee belong to the same family, and it is not impossible that some of the sporting of cinchonas on estates might be due to the pollen of coffee fertilizing the ovules of cinchona. The pollen grains of coffee and cinchona are very similar. In the same manner, species near akin may hybridize, which is not at all uncommon in nature. The result of such is termed a *species hybrid*. Fertilization is much easier between varieties near akin, and is exceedingly common as every gardener knows, with varieties of genus Brassica, the resultant of such is termed a *variety hybrid*. The term *cross* if retained should be used for this kind of hybrid. Thus we have :—

Genus hybrids	or	Bigeners,
Species ,,	or	Hybrids,
Variety ,,	or	Crosses,

and from these hybrids we have *derivative* hybrids or combined hybrids.

When plants are *protogynous* (that is when the stigma of a flower is receptive before the anthers of the flower are mature), which is a common occurrence, we have a kind of compulsory hybridization. Now looking at the offspring of planted seeds of cinchona or of fallen seeds, and observing the great sporting which prevails, it is evident that hybridization has taken place.

The treatment of coffee leaf-disease is still pursued, but with no definite effects.

Agricultural education is also taken up in the paper referring especially to work done in the Madras Presidency. The report of the Director of the Botanic Gardens is given in full showing us the work done there in the way of introducing new plants and of experiments carried out. Long may this useful Journal of Agricultural Information live.

———

(From another correspondent.)

I congratulate you on the completion of the first volume of the *Tropical Agriculturist*, and a goodly volume it is with its 1088 pages, and an index as complete and comprehensive as the book itself.

When I received your first number (some twelve months ago) I thought you would have some difficulty in filling up such a number every month, but, whether owing to the extensive and varied nature of your subject, "Agriculture," or to your wondrous faculty of aggregation, you have certainly succeeded in producing a voluminous volume of carefully collected and well written information—a volume which ought to be found on every planter's table and in every merchant's office, as well as in every kachcheri and library in the tropical world.

Perhaps you will allow me space for a few remarks on No. 13, which lies before me. On pages 1001-7 an old friend writes in his usual graphic and interesting style on "New Products in the Lowcountry." But is he not a little behind the age, in this day of "Scowen's transplanters" and Liberian coffee seed at R1 per 1,000, with his "baskets" and consequent expenses and trouble in watering, etc.? His reason for using baskets is that by this plan he has fewer plants destroyed by crickets. If he knows the percentage of destruction in the nursery let him put in extra seed sufficient to cover the loss, and in ten months' time he will find his undisturbed plants will be far stronger and better than those coddled in baskets and will cost him less per thousand too, which is not an unimportant item in such calculations. As to "shade" for cocoa, Mr. Prestoe (page 1079) says:—"Some varieties require shade to thrive well, others do not." My opinion is that, with the variety generally cultivated in Ceylon, shade ought to be provided for two years or so and then be removed. The most inexpensive and efficient (from the beginning) shade, with a minimum of demand on the resources of the soil, will be found in the trees already standing on the land to be planted. Let the planter judiciously —*i. e.* taking into account the nature of the tree, the size, etc., of its roots—select and mark off trees sufficient for slight shade and breakwinds; let the "woodman spare such trees." The planter will not "burn off" such a clearing: he will simply lop and clear sufficiently to hole and plant. Cocoa planting under such conditions will have fewer failures and will be less liable to be attacked by white ants.

The communication signed "Udagama" (p. 1004) will repay perusal. But if "Udagama" can *afford* to be *wise*, he will not allow his 3 year old cocoa trees to mature and ripen as many as 60 pods each; let the trees pass their 4th year first. *Hemeleia* on Liberian coffee:—On a small clearing close to my house and under constant observation I find that it is only small, sickly, badly-grown trees that are affected. The question is, whether the sickly state of the tree is the cause or the effect of the disease. I am strongly of opinion that it is the *cause*. If such trees are "centres of infection," *which I doubt*, or whether this is so or not, all such trees ought to be rooted up and burnt; otherwise they will "cumber the ground" and *may* injure their neighbours.

I do not believe in any special "disease-resisting Liberian coffee" (see page 1073). My belief is that all healthy, well-grown trees will resist disease. But as it is as well at this stage of our knowledge of the subject to take every precaution and also because the best seed ought to be produced by the best trees, all seed in future should be taken from so-called "disease-resisting trees." From Mr. Carry's letter (p. 1018) it would appear that the battle of the "vaporizers" is approaching, Carry *vs.* Storck. I have read with pleasure your article on page 1084. I am a believer in the "adverse influence of the sun spots" theory and imagine that our long-suffering friend *C. arabica* would be better of with less vapour and more sun. Those rays of the sun which produce chemical effects are called "actinic rays," and it is the opinion of scientists that with the maximum of sun spots we have the minimum of actinic rays. Ten years ago, Professor Roscoe invented an instrument to test the truth of this theory. The instrument was handed over to the Russian Government, and the results were to be known in about 10 years. Have you heard of this instrument, or of the results of its use? During the perihelia of the four major planets, the sun-spots visible to us will increase or decrease in proportion to the number, etc., of the planets appearing at the earth side of the sun. If Jupiter and Saturn happen to be at our side of the sun, the sun-spots will doubtless be very few and so the much-dreaded perihelia may be a blessing in disguise. If, however, the sun comes between us and our gigantic neighbours, the sun spots will increase at the *earth side*, and grand disasters *may* follow. Can "Isis" enlighten us on this point? Gardeners will find on page 1021 an interesting article on "Root-grafting Roses." Land owners in the neighbourhood of the great mail port might with advantage study the articles on "Orange Cultivation" on pages 1027 and 1030. Planters who wish to increase their "screw" will find some hints on the subject in an article by Mr. Cooper on page 1032. I commend the article on the cultivation of the "fragrant weed," page 1035, to all whom it may concern, but especially to the notice of our pioneers at Mahatissarama (I think that is the name of the tank visited by the Governor the other day). Cinchona and tea planters have a large share of attention. "Graphite" belongs to the agriculture of a former age; still a notice of it is not out of place here (page 1061), for it may form the "mineral wealth" of some lowcountry estates. Merchants and planters will read with profit the extracts given on pages 1078-79-80, from Mr. Prestoe's report. His recommendation in paragraphs 347 and 348 are worthy of consideration here. We shall soon require a "CENTRAL RECEIVING FACTORY" for both Liberian coffee and cocoa, where small proprietors can sell their produce and where Liberian coffee and cocoa can be properly prepared for the market. Wishing you every success and a large circulation of the *T. A.* past, present and to come.

NIREFONOS.

TEA AS AN INVESTMENT.

A good property for investors should have a capital not exceeding five hundred rupees per acre. We know that many fine gardens have not cost so much as this, and we could also point to some which have cost nearly three times this amount. As a general rule, five hundred rupees per acre should be the capital value of a good garden. This then is the first thing to find out. Another important item is the yield. A garden in bearing should give four hundred pounds per acre. Many give more, but, if the property turns out this quantity all round, that is another point in its favour. We next come to cost of production: that should not exceed eight annas per pound. We are quite aware that, in most of the Assam districts, labour is very much higher than in other localities, but the climate of Assam is so much more favourable to quantity, that we consider the question of labour equalized. In Assam, what with deaths, runaways, and bonuses, we are quite prepared to hear that each adult costs his company eight to ten rupees per month, while in the Upper Provinces labour can be had in abundance at rates running from four to five rupees. The climate there, being, however, not so conducive to heavy flushing, we do not look on the advantage of cheap labour as being of such primary importance after all.

An important point is: what does the future of tea hold out by way of inducement to investors? This important point turns on that other: will last season's prices be maintained or not? Three causes are said to have operated last season to keep the prices up, and the question is: to which of these was the increase

mostly due? These causes were :—(1), the inferior quality of the supplies arriving from China ; (2), the unusually fine quality of the Indian teas, and (3), the extremely low prices ruling for Indian teas, during the preceding two years. The prospects of the coming season, and indeed of the immediate future of tea, depend on the more immediate cause of the recent high-ruling rates. If the first of these three causes has had a predominating influence, or, if, even the third has had a controlling effect on purchases, and consequently on rates, then we may look forward to the future with considerable misgiving. If, on the other hand, the second of the above-noted causes has been the ruling power in the change, investors may look to the future with confidence. A general feeling is abroad to the effect that the real cause of the sudden advance made by Indian tea was the abnormally low prices ruling during the last two years, which induced a wider sale. This, it is felt, was assisted by the low quality of China teas arriving during the same period. We are not prepared to endorse this view, as we consider the real operating cause to have been improvement of Indian tea itself, helped certainly by the inferior quality of China tea in the market, and we shall endeavour to prove our position. That the low prices of Indian tea prevailing for some time is not the cause, is, we think, proved by the fact, that the demand did not cease when these abnormally low prices gave place to the higher—much higher—rates of which we are speaking. Again, if the previous prices of Indian tea were abnormally low, those of China tea were even proportionally lower still, and we do not find that the result was an increase in the consumption of the latter. We shall now give the actual figures for the past three years, which will put this in a clearer light :—

			lb.	lb. per head
	INDIAN TEA.			
Consumption,	1879	...	35,242,800	1·02
Do.	1880	...	41,605,200	1·20
Do.	1881	...	48,862,296	1·39
	CHINA TEA.			
Consumption,	1879	...	125,409,728	3·63
Do.	1880	...	116,965,642	3·36
Do.	1881	...	111,363,493	3·18

In Indian tea the annual increases were ·18 and ·19lb per head, whereas, in China, the decreases were ·27 and ·18lb per head. It will be seen from this that what we call the great increase in the consumption of Indian tea in 1881 was really not greater than it had been in the previous year. This seems to us to dispose of the remark that the low prices caused the increased demand. These figures prove that the consumption of Indian tea has been steadily improving, while that of China has been as steadily declining. We are thus forced back on the second cause as the real one. The tea made last year was very much better, and immediately, in consequence, commanded a better price. It is also worthy of note that the sudden increase which took place in the home value of Indian tea was synchronous with the materially decreased manufacture of under-fermented, under-fired, pungent tea which we had been making for several years past. Indian tea was thus adapted to be drunk alone and unmixed, and the true flavour of good tea soon had the natural effect of increasing its popularity. We hold, therefore, that, barring accident, the tea shareholder can look ahead with considerable confidence.—*Indigo Planters' Gazette.*

DARJEELING TEA COMPANY.

(From the *Planters' Gazette*, May 15th)

The 17th annual meeting of the above Company was held at the office, in London, on the 1st inst., when the directors presented a very satisfactory report of the Company's position and prospects, which was unanimously adopted, and a dividend at the rate of 8 per cent declared. The following extracts will be read with interest by all who are engaged in the tea industry in the East, and we may point out in passing that the example set by the directors of this Company in giving full information to their shareholders might with advantage be followed by those of other concerns occupied in tropical cultivation :—

"The directors consider, that, on the whole, the result of the past season's operations has been of a very satisfactory character, exhibiting, as it does, a nett profit of £12,088 17s 8d, which is equivalent to very nearly nine per cent on the paid-up capital of the Company.

"The weather during the past season was unfavourable for the production of large flushes of leaf, and consequently the total quantity of tea manufactured amounted to only 481,674 lb, being 38,326 lb below the outturn which was estimated by the manager at the commencement of last year.

"The alterations in the treatment of the plants during the spring, and in the system of plucking the leaves, as described in the directors last annual report, have been generally approved and although the quantity of tea may have been somewhat diminished thereby, nevertheless there is no doubt of the fact, that the quality of the tea was vastly improved and the proportion of broken and common descriptions greatly reduced by the alterations which were carried out. In addition to which the condition of the plants has been much improved, they have increased in size, and have now a fine growth of young wood upon them, which must make them capable of producing larger flushes of leaf than formerly.

"It is satisfactory to state that an average price of 1s 7.64d per lb was realized for the crop of tea, which is 2½d per lb in excess of the average price for the previous year's crop.

"For the information of the members the following statistics are given, showing the operations of the Company during the last four years :—

Total Outturn of Tea and Cost at Plantations.

In 1878,	1,393 acres,	511,849 lb.	at 367 lb.	per acre,	R189,115
„ 1879,	1,496 „	475,593 „	318 „	„	185,822
„ 1880,	1,534 „	540,606 „	352 „	„	186,982
„ 1881,	1,534 „	481,674 „	314 „	„	191,222

Gross Expenditure and Cost per lb. of Tea, after deducting th difference in the Rates of Exchange.

In 1878,	£26,695 ...	cost per lb., 1s 0·69d
„ 1879,	£26,123 ...	„ 1s 1·42d
„ 1880,	£27,337 ...	„ 1s 0·31d
„ 1881,	£26,646 ...	„ 1s 1·58d

Account Sales Weight of Tea, Average Prices, and Proceeds

In 1878,	504,619 lb.	at 1s 6·19d,	£38,259
„ 1879,	467,014 „	1s 5·23d,	£33,550
„ 1880,	532,783 „	1s 5·10d,	£37,977
„ 1881,	470,863 „	1s 7·64d,	£38,538

Dividends Declared.

On 1878 crop of tea,		9	per cent.
„ 1879	„	6½	„
„ 1880	„	7½	„
„ 1881	„	8	„

DIVIDEND.

"The directors beg leave to recommend that a dividend at the rate of 8 per cent., clear of income tax, be now declared, and that the same be made payable on and after the 1st May instant, which will absorb the sum of £10,833 12s, and that the balance of £1,255 5s 8d be carried to the credit of the reserve fund.

TEA SEASON, 1882.

"The estimates for 1882 have been carefully prepared by the manager, and although it must at all times be a difficult matter to estimate with accuracy what large numbers of tea plants, covering an area of 1,534 acres, are likely to yield from April to

November, nevertheless, it is believed from past experience that the estimated outturn of 6,650 maunds, or 532,000 lb. of tea is likely to be realized, should fair average weather prevail throughout the season.

"Assuming that the estimates will be realized, the cost of production may be stated as follows :—

Outlay on Plantations	0s 8·56d	per lb.
General outlay	0s 5·64d	,,
	1s 2·20d	per lb.
Less difference in exchange ...	0s 1·81d	,,
Cost	1s 0·39d	per lb.

THE RATE OF INCREASE IN CONSUMPTION OF INDIAN TEA IN BRITAIN FROM 1874 TO 1881,

(averaging 16 per cent per annum), is thus given in the *Indigo Planters' Gazette* :—

	Deliveries. lb.	Increase. lb.	Increase. per cent.
1874 ...	17,756,700 ...	...	...
1875 ...	23,273,900 ...	5,517,200 ...	31
1876 ...	26,733,500 ...	3,459,600 ...	15
1877 ...	28,011,500 ...	1,278,000 ...	5
1878 ...	36,766,700 ...	8,755,200 ...	31
1879 ...	35,243,200 ...	1,523,500 ...	4
1880 ...	41,605,100 ...	5,361,900 ...	15
1881 ...	48,862,300 ...	7,257,200 ...	17

During the past seven years then, the average increase has been at the rate of 16 per cent each year over the preceding season. A consideration of this ought to guide planters in extending, but it does not, and the flooding of the market at home is largely due to this disregard. When a season proves unusually good, extensions are the order of the day, and it seems to be entirely overlooked that this same sanguine feeling takes possession of the minds of all planters simultaneously, the result being a very largely increased area, which comes into bearing a few years later on, when prices may be at zero. If the produce of newly planted land was immediately available, there might be some excuse for this rashness, but the state of the market four or five years after any given date has no connection with that first point. Now we find that the general increase ought to be about 16 per cent. every year, and at first sight the simplest mode of keeping pace with the increasing demand would be to add 16 per cent. of new clearing every year ; but this would be fatal, as no account is taken of entirely new gardens, which are continually being opened out, and the produce of which is steadily coming to market. Taking all these things into consideration, we imagine that an annual increase in the case of gardens already producing should not exceed five per cent. every year, and we feel convinced that this would not lead to the markets being glutted on the one hand, or starved on the other.

We are not believers in the theory that the cure for an overstocked market is to make fine teas only. Doubtless it would speedily reduce stocks, but this would be effected at a heavy cost. A large proportion of consumers cannot afford to pay for expensive tea, and a reduction of stock of such qualities would drive consumers to the China article ; and besides, we believe the theory to be mischievous as applied to the financial working of a garden. We know that the prevailing feeling in this connection is, that you can only get a thoroughly good quality by limiting production—by plucking lightly. This we hold to be a fallacious theory, and we shall give our reasons for holding that opinion. We will suppose a garden whose manager is bent on making five maunds per acre of fair all-round tea, while another has estimated for four maunds, but of superior quality, or to speak more correctly, of finer classes. The latter ought to make—and we are now speaking in round numbers—one maund Pekoe, two maunds Souchong, and one maund Congou. The other ought to make precisely the same, with one maund Congou extra. Now the theory believed in by many being, that you cannot make such fine teas where you have a larger quantity of low class leaf in the factory, and it is just at this point that we join issue with the holders of this theory. We insist that the one maund Pekoe, and the two maunds Souchong of the "quantity" garden need not necessarily be of lower quality than the same teas of the "quality" garden. It is true that the one has more to make each day than the other, but that is a question of establishment. If the same number of factory hands be employed in both cases, then the theory holds good, for if the proper number of men to make four maunds are employed, it would be absurd to look for equally careful manipulation if they are called upon to manufacture five maunds. Another reason frequently advanced in favor of quality, as against quantity is, that the bushes are not so heavily plucked. Let us see what this belief amounts to. The quantity short-plucked being one maund per acre, represents, say, 320lb. of green leaf. Allowing for vacancies, and reckoning plants to be 4′ + 4′ we may estimate the number of bushes per acre at 2,500, and this saving to the bush, is thus at the rate of two ounces. Considering the quantities removed by the pruning knife every year, we look on this other relief as being utterly insignificant. Regarding the proper quantity to pluck, for bush, we hold that a pretty safe rule is to pluck all leaf that will make tea, the only exception to this rule being during the early spring season, when the entire crop consists of single shoots, and before the second and subsequent shoots have had time to grow out from the axils of the first. To pluck heavily under such circumstances would be the extreme of folly. Besides, what do five maunds per acre amount to after all ; one maund of tea requires about 4 maunds of leaf, hence 5 maunds of tea per acre is equal to ·714 ton per acre of green leaf. It cannot surely be seriously advanced that with such a plucking the bushes would be the better of a rest. From a consideration of these points we arrive at the conclusion that it is a mistake to suppose that quality and quantity are opposed to each other. The aim of the intelligent planter should be quality *and* quantity. The limitations of outturn must therefore take the shape of a limitation of the size of gardens, since it is always good policy to pluck all flushes adapted for tea-making,

TREES ON COFFEE ESTATES FOR SHADE, SHELTER, AND OTHER USES.

Circumstances of climate, such as protracted drought and parching winds, may render shade indispensable, and we feel bound to bow to the better judgment of the large majority of planters in Southern India who consider shade necessary for their cultivation (see the letter elsewhere), although in Ceylon the conviction is next to universal that where coffee will not grow without shade it had better not be cultivated at all. But lines or belts of trees are valuable as shelter against tearing winds, which are most injurious to coffee apart from the fact that they infect the leaves, which they do not blow off the bushes, with the spores of the fatal fungus. In many parts of Ceylon, too, where the climate is rainy and the subsoil damp, trees are valuable for purposes of "suction drainage." In planting, whether for shade or shelter, it is, of course, desirable, if possible, to use trees valuable for

their fruit, timber, or juices. The jak is valuable for fruit and still more so for timber, but it puts on a dense umbrageous head. It would, therefore, if adopted, require free and frequent pruning. The foliage so removed would make excellent fodder for animals. We suspect, however, that the jak would leave but little nutriment in the soil for the plants in its immediate neighbourhood. The *erythrinas* and the *albizzia moluccana* used for shade in Java, and the various Indian figs preferred in Southern India are of little for timber or otherwise than as shade trees, unless indeed *ficus elastica* is one of the figs adopted by our friends over the way? If that and other rubber-yielding trees could be grown amongst the coffee, whether for shade or shelter, a double benefit would be gained. Some rubber-yielding trees grow at high altitudes; some at low elevations only; while some have a wide range. So that the right sorts could be chosen with reference to altitude, heat and moisture. On our hill estates in Ceylon tree-growing for shelter and drainage purposes has largely extended of late years, the fast-growing Australian trees, especially the blue gum, the black wattle, and *grevillea robusta* being preferred. But many other trees, and amongst them those yielding caoutchouc could be added with advantage. We should like to have the views of local correspondents on the most recent experience of tree planting in connection with coffee cultivation.

SEEDS FROM SOUTH AMERICA.

A planter, who is expecting seeds from South America, writes :—

Regarding the different seeds soon to arrive from South me rica: they have been procured principally in Bolivia from the districts of "La Paz" and "Jacua."

The *Calisaya morada* is from the former district (whence Ledger's seed came), and I need not add that it is the variety yielding the most valuable bark known. I am told that two only are thought worth cultivating (corroborating what has been said as to this elsewhere), the other doubtless being *C. verde*. This seed has been procured from an unquestionably reliable source, the sender having himself been 18 years resident, and both privately and in business intimately acquainted with many of the principal landowners and merchants throughout the country. He writes that it is only as an "immense favor" that this cinchona seed has been supplied, and it is further stated to be "A 1".

As for the other seeds, the description Markham gives of the different plants and their various good qualities induced me to write for them, now more than a year ago. But from all accounts, the world still moves slowly in South America, and the late war has interfered.

The "Maiz Blanc," the best of several varieties the Incas are said in olden days to have brought to their present perfection (if I remember right) by "selection of seed," must be a very grand specimen of maize, and should prove a success in at least the *high portions* of Uva, and possibly in the higher and dryer parts of Dimbula and Dikoya. It *may* also do well lower down in Uva, but I fear not elsewhere in Ceylon. Peruvian cotton, however, I believe firmly, will prove an entire success in the dry portions of the lowcountry. The rich lands about Trincomalee should suit it to perfection. It is the native of a very dry climate; the yield is spoken of as being very large, and the quality excellent, and I have every hope of its proving a really valuable introduction. The moister districts, at the lower altitudes, are already superabundantly provided for by many well-proven, highly profitable cultivations; and it is for the *dry* portions of the country, though deficient in rainfall, frequently possessing a *splendidly* rich soil, that it would seem to me suitable introductions are still needed, and should now be sought out. Ceará rubber and *possibly* tobacco are the only ones I have as yet heard as likely to be successful without irrigation. Coca ought to do well at the higher elevations here, and I do not see why the natives in the East, as in South America, should not work the better, and preserve a higher standard of health too, by its use. Whether they can be induced to take to it is another question; but it would seem to be well worthy of a trial. In South America it has become an *absolute necessity* to *millions;* and, if this could only be brought to pass amongst the lower orders of both *Hindus* and *Chinese*, it would not only possibly prove directly beneficial in itself, but probably tend to lessen a craving for opium and other *pernicious* (I exclude tobacco) narcotics, and for spirits: the consumption would perforce become enormous, and a staple industry established. The Yungas (Incas!) coffee is also from Bolivia, and I gather that it is there grown very extensively, being (in South America) regarded as the *finest flavoured of coffees*. This I did not write for, and it is evidently sent under an impression that it would be a valuable addition to a coffee-growing country. A small quantity was sent me several years ago, but I was in England at the time, and I do not remember to have heard on my return that it had even been sown—probably not.

CEYLON COCOA TOPPING THE MARKET.

To the Editor of the Ceylon Observer.

Colombo, 15th July 1882.

DEAR SIR,—The following extract from the report of the London brokers who sold the parcel of "Amba" cocoa, shipped by us per S. S. "Orion," will probably be of public interest.—Yours faithfully,

SABONADIÈRE & Co.

(*Extract from Broker's Report on 72 Bags Cocoa per S. S. "Orion" from Colombo.*)

We have nothing new to remark as regards this shipment. The prices are exceptionally good, the cocoa is of exceptionally fine quality, and the competition was general and good. We believe it is generally wise to let well alone, and we can only hope that your cocoa may continue to come of similar good quality, and that the buyers may continue to give us not less than recent prices:—

Amba	Bags 20	@	118s	per cwt.
A.	„ 27	„	120	„
B.	„ 20	„	114	„
T.	„ 5	„	70s 6d.	„
	72 bags			

You will see that, while the bulk realized 120s, the average of all round was over 114s *per cwt.*, which reflects great credit on the care bestowed throughout in curing.—(True extract.) S. & Co.

[We are glad to learn that there is now a nice parcel of 114 cwt. of the same mark of cocoa at the wharf waiting shipment per S. S. "Quetta."—ED.]

CEYLON COMPANY LIMITED:—REPORT.

DIRECTORS:—George Suart Simpson, Esq., Chairman, Charles Joseph Braine, Esq., Major-General Christopher Palmer Rigby, Patrick Francis Robertson, Esq., Christopher Barker Smith, Esq., Richard Ottaway Turner, Esq.

Report: To be presented at the twentieth annual meeting, to be held at the Cannon Street Hotel, in the city of London, at 2 p. m., on the 27th June, 1882.

1.—The Directors have to report that the coffee crop from the Company's own estates in Ceylon, 1881-82, which they have lately been realizing, turned out in quantity

about what they reported as expected in the half-yearly report of 20th December 1881, viz., about 18,500 cwt.

It was about	28,000 cwt.	in	1878—1879
„ „	14,300 „	„	1879—1880
„ „	13,650 „	„	1880—1881
And it is now	18,500 „	„	1881—1882

They regret to say the prices realized have been on the average from 5s to 6s per cwt. less than last year, or about 11s per cwt. less than in 1879-80: this, on about 18,500 cwt., materially reduces the credit to profit and loss for Ceylon business, but still that credit this year is £26,176 4s 11d, against £17,214 4s 7d last year.

2.—As to the ensuing crop, 1882-3, the advices are imperfect and at present not favourable: the weather, January to March, was bad, and the blossoms were poor and injured: some improvement has however, since taken place, which may favourably affect the crop, and the Directors hope for increased quantities of tea and cinchona.

3.—The crop of sugar from Mauritius of 1881-2 on the Company's estates was about 5,600,000lb. against 4,362,804 lb. in 1880-1, as per previous reports. The prices in the average were 2s per 100 lb. higher: thus, and from absence of the unfavourable debits which appeared in last year's report, the loss of last year, £21,413 1s 3d is changed this year to a gain of £8,124 12s 11d. The Directors are very glad also to inform the proprietors that three out of the four estates owned by this Company at Mauritius have been sold and paid for in cash: they are also glad to state that the item, £64,026 3s 3d, "Mortgages and other securities at Mauritius," as per report of last year, has been all realized and credited in the present accounts; the only remaining estate of the Company at Mauritius, Chamouny, left a fair profit last year, and the account of its coming crop is favourable. The above realizations have caused a further loss of £14,750 10s 3d, which has been carried to the debit of estimated deficiency in value of assets. The Directors beg to acknowledge the great assistance they have received from their able agents, Messrs. Ireland, Fraser & Co., in the general management of these affairs.

4.—To the credit of the estimated deficiency account, there have been carried further credits from shares forfeited £3,437 12s 9d, and shares surrendered £4,640, and the balance now at the debit of this account is £305,677 0s 3d against £299,004 2s 9d.

And now further as to the accounts:

5.—The balance sheet for the past year is annexed; the main assets are taken at the valuations of the 31st of March 1878, as has been always done since that date. It has not been found possible to have new valuations, opinions differing widely, particularly as to the value of estates partly planted with cinchona among the coffee, and in separate plantations; the scarcity of money, and fluctuating and unseasonable weather, also making values generally changeable and uncertain. The Directors are giving much attention to the increase of cinchona and tea, and generally to making the most judicious use possible of the properties.

The landed and other properties in Ceylon stand this year at £569,862 19s 7d against £566,003 16s 4d last year. Full details of the acreage under coffee, tea, cinchona, and other products in Ceylon will be found in the annexed schedule.

The cost of cinchona cultivation in reference to trees not matured is shewn this year under a separate heading. Part of this amount was expended in previous years, but was included in other accounts. As the bark comes to market hereafter and brings in revenue, this outlay will be gradually recouped: further expenditure on new planting will on the other hand be debited to this account year by year.

The investment amount at Mauritius is now reduced to £61,190 14s 6d, and the general balance at the debit of profit and loss is £72,928, against £81,976 0s 9d last year.

On the other side full details are given as to capital paid up; the amount of debentures outstanding is reduced from £78,238 10s to £54,600, and the interest upon them from £6,434 10s 6d to £4,123 1s 9d. The liabilities of the Company altogether apart from capital, as compared with last year, are reduced to the extent of £150,228 17s 7d.

6.—The crop of tea from the Company's estates in Ceylon amounted last year to 123,000 lb. A special manager for this article has recently been appointed, under whose direction it is confidently expected that the Company's tea will still further improve in quality, and the Agency business be increased. Cinchona has been largely planted, and the number of trees and plants of it now growing on the Company's estates has been estimated at 4,847,398; many die before maturing, but are replaced by others, and even if one-third only arrive at maturity, a very considerable support is being built up for future years.

India Rubber.—Continued attention is being paid to this cultivation, and to the introduction of new varieties.

7.—The law suits in Ceylon are still pending. The Directors assure the proprietors that they are making every effort, with the assistance of their able legal advisers, to make progress with them. The small legal case at Mauritius the Company are again advised has been decided in their favor with costs.

8.—The Directors decided it was necessary to make another call on the proprietors, payable on the 10th May last, of £1 per share; they are glad to say it was promptly met, and to the present date about £21,540 has been paid of it, and every possible attention is being given to what is outstanding: these receipts of course are not in the present accounts.

The following is a memorandum of the previous calls, and with the full details in the balance sheet, supplies all particulars of the capital account:—

Fully paid shares owned by proprietors	...	4,375
Shares owned by proprietors and liable to further calls	...	28,769
(Of these 28,769 shares there were arrears of calls due in respect of 3,087 on 31st March last amounting to £17,545 10s for part of which some security is held.)	...	
Total shares forfeited and surrendered	...	4,356
		£37,500

The Directors wish again to express their sympathy with their fellow-proprietors at the continuous calls without dividends; they are necessary, and it can only be hoped that time and good seasons, industry and unceasing effort, may give some advantageous result.

9.—The Directors much regret to have to inform the proprietors of the death of their esteemed colleague, Major-General Burn, since the last meeting. Mr. G. S. Simpson and Mr. P. F. Robertson are the two Directors who retire by rotation this year, and being eligible, will be proposed by the Board for re-election.

10.—The shareholders will be requested to elect Auditors for the ensuing year.—GEORGE STUART SIMPSON, *Chairman*.

St. Clements House, 27 Clements Lane, E.C., 17th June, 1882.

THE TEA ENTERPRIZE IN CEYLON: ESPECIALLY WITH REFERENCE TO THE REDEMPTION OF UNPROFITABLE OR ABANDONED COFFEE LAND.

Having, from a period dating back a full score of years, pressed on the coffee planters of Ceylon the advisability of not trusting their fortunes exclusively to one produet, but to give due attention to cinchona and tea, we are naturally pleased to see our advice so extensively and, for the interests of planters and the colony, so beneficially followed. The aspect of the tea enterprize specially dwelt on by Mr. C. Shand, in his reassuring letter which we publish today, is that of the redemption of unprofitable or abandoned coffee land by planting it up with tea. This process, Mr. Shand holds, can be accomplished so inexpensively, that, if but half the average quantity of leaf yielded by estates cut out from the primitive forest is obtained from such resuscitated land, the enterprize in the one case will pay as well as that in the other. With just the serious qualification mentioned by Mr. Shand, of the effect of the present crisis in the coffee enterprize on our supply of immigrants, there can be no doubt of our

superior position in regard to labour ; while by the introduction of such machinery as rollers, driers, &c., a much smaller number of labourers will suffice. While agreeing with Mr. Shand that, as a general rule, it costs less to bring an acre of coffee, tea, or cinchona land into cultivation here than is the case in India, we cannot help suspecting that our correspondent has taken an extreme instead of an average, in putting down R900 to R1,000 per acre as the rule in India for tea estates. Some of the older estates have, no doubt, cost even more than R1,000 per acre, but recently opened plantations stand at a much more moderate sum. In most of the estimates we have seen, R500 per acre for tea in full bearing, that is when the bushes are over four years old, has been the average figure adopted. There is this to be said, however, that greater expenditure must be incurred in India, even where terracing is not resorted to, in clearing away all timber so as not to provide food for the white ants which subsequently attack the tea bushes. There is another difference in the necessarily expensive process of clearing streams running through estates, not only of timber but of large stones. No doubt a good deal of the expense of this process is recouped by the additional space on the banks of streams gained for planting purposes. Our soil in Ceylon may not be equal to that of the Terai or Dooars in absolute fertility, but we have compensation in a climate which, while sufficiently moist and forcing, is generally far more salubrious than that in which our competitors in India are compelled to work. As regards soil, indeed, it is most important to know that in stiff ferruginous clay, not favourable for coffee and very adverse to cinchona, tea will flourish. Considering that the average yield per acre in Assam and Cachar is not more than 280 lb of dried tea, * it is gratifying to hear of 500 lb per acre being gathered on an estate of medium altitude in Ceylon. Indeed Mr. Shand feels himself justified in taking 500 lb per acre as the Ceylon average, in his argument that half that yield on reclaimed lands will pay well. There can be no question that, all abatements made, Ceylon seems destined to become one of the great tea producing countries of the world. India has had the start in the race, but we are following energetically in her wake. We are not aware of any elements of superiority in the case of Japan, while, as regards China, there are not only the internal imposts to which Mr. Shand alludes but an onerous export duty to handicap the tea industry. In his desire to be reassuring, Mr. Shand may have somewhat understated the cost of producing tea in Ceylon both on virgin soil and replanted land—those who have gone carefully into all the elements of expenditure will be able to judge,—but even supposing an appreciable percentage is added, the case is still good and most encouraging, and the planting community will feel grateful to Mr. Shand for his timely words of cheer, based as they are on considerable experience. In July 1879, Mr. C. H. Hay of Doloshagie was good enough to send us the result of his experience so far in Ceylon in a form which we regret to say has not yet seen the light. Better late than never and perhaps the publication of the statement now may induce criticism and bring us the results of further experience :—

"I send you the working out of half a month of this new year beginning July 1st, as you ask if any one can say what 1 lb. of tea costs to make. This is just copied from my tea book.

Date.	Green Leaf.	Pluckers.	Withering.	Rolling.	Drying.	Sifting.	1 ct. a lb. Charcoal used.	Tea made.

Average rate of pay 36 c.

The boxes for holding 80 lb. pekoe, 100 broken pekoe, 70 p souchong.

23 × 18 × 18 cost to make, wood, work, nails, hoop iron everything R2·69 per box. This does not include the carriage, nails, and hoop iron, but this is very small. Of course, the charcoal used is for heating house, drying tea and also for redrying *other tea* before packing. I have not exactly found out what a sheet of lead costs, as I have not been able to count 1 cwt. yet. Of course, the longer tea is made the cheaper it must become, because all new appliances have to be taken into consideration, but this, as you will see is the bare amount expended in making 658 lb. or 8 maunds 9 seers costing R175·86 or 26·7264 per pound. I may have made some mistakes but hope you will correct me.

I am sorry I cannot send more minute details but later on I may find a reduction in some thing. For making about 5,600 lb. I find last year it came to 40 cents closed in the box but then so many things came in this account.—July 24th, 1879.

We hear it said sometimes that the pioneer of tea among Ceylon planters—Mr. Taylor of Loolcondera—has not made the cultivation a profitable one ; but we are in a position to state on the best authority that this is a mistake for the tea-plantation in question is giving "a very fair return."

ORANGES IN FLORIDA.—Reports from Florida show the orange crop of the past season to have been very large, the number of oranges shipped being 28,941,760. A still larger yield is looked for next season.—*Public Opinion.*

RICE.—The following as to the Louisiana Rice crop is from the New Orleans *Sugar Planter* of the 6th May :—"We cannot recall a previous season when the crop of this cereal presented such favourable conditions as at present, and we have no doubt that the product this year will be the heaviest in the history of rice culture in Louisiana."

JADE STONE.—In the April number of the *Monatsschrift für den Orient* Lieutenant Kreitner writes on jade stone. It is found, he says, so far as we know at present, only in three places on the globe:—in New Zealand, on the northern slopes of the Karakorum mountains, and in northern Burmah. The fact that it is found in Europe and America among archæological remains gives the stone a peculiar interest. It has not the value in mineralogy that Asiatics, and especially the Chinese, give it. It is of various colours : white, grey, brown, red, and green—the last being the most common. China is supplied by the Burmese mines, through Bhamo, which is the entrepôt for the trade. The stone must exist there in large quantities, for it is discharged in cargoes from boats at Bhamo. Quality, not quantity, is the test of value. The cutting and shaping of the rough stone into ornaments is in the hands of single artists all over China. In Canton a whole quarter of the city is occupied by workers in jade. It is universally in use as an ornament by all classes, from the highest to the lowest. Occasionally it is exceedingly expensive, a small bracelet in some instances costing as much as 60$_0$ dollars. This it is that makes it overprized in China. —*Japan Gazette.*

* 280 lb. is the official return which includes young clearings.—Writing to us in January 1879 with the Government statistics, Mr. Baker of Assam said:—"Taking average gardens in fair cultivation over three years old and upward, 320 lb is about the outturn. But a 10 year old and upward garden is doing its 500 lb per acre I think all over the province, and this without manure, to which nobody seems to take at all."

Correspondence.

To the Editor of the Ceylon Observer.

CINCHONA MICRANTHA.

Lindula, 22nd June 1882.

DEAR SIR,—Can you tell me if any cinchona micrantha bark has been analyzed in Ceylon? If so, what was the analysis? In Mr. Owen's book, I note he says they are poor in fine alkaloids, and Markham says they are a fine species. I have 300 trees here, about two years old, and I would like to know if they are of any value, before I pull them out.

How would officinalis do grafted on to the micrantha stocks?—Yours truly, W. S.

[We regret that this letter should have been delayed. *C. micrantha* is almost entirely destitute of quinine and scarcely worth cultivating for the sake of the inferior alkaloids. As the trees grow vigorously, however, our correspondent ought to coppice and graft them, harvesting and testing the bark, of course. Like the "inferior" calisayas, the micrantha tree may be improved in the Ceylon climate and soil.—ED.]

COFFEE-PLANTING IN COORG; AND GENERALLY.

Amutty, Coorg, 29th June 1882.

DEAR SIRS,—In the issue of June 13th of the weekly edition of your valuable journal, I notice an article on the coffee enterprize in the Bamboo district of Coorg. It is not my intention to enlarge on this subject, seeing that in the main the article is correct; but I think that the cordial thanks of all interested in that part of the country are due to you for your expressions of kindly feeling in wishing us a continuance of our good fortune. I am, like the griffin at an after-dinner speech, "unaccustomed to public speaking," &c., unaccustomed to public writing, yet I feel that, if a few words from me can be of any use to others engaged in the above industry, it will not be time wasted. For a number of years I have watched with considerable admiration your own exertions so strenuously exercised in whatever was calculated to promote the good of your fellow-colonists, and I am sure I can confidently assert that these have not been fruitless. You are very good, too, in giving room to others who are pleased to give ventilation to their opinions and ideas and are having the same end in view, namely, of being useful in their day and generation. Hence, I would beg for a small corner, if you please, to say a word or two on the subject of coffee-planting generally, but particularly on the letter which appeared in your issue of the 14th June, signed "Mahseer," and dated Munzerabad. It seems to me a very delicate matter to pronounce an opinion dogmatically on any subject, but looking back to a considerable series of experience both in the Ghaut and Bamboo land of Coorg, if there be one thing about which a difference of opinion can scarcely exist, I think it is the necessity of growing coffee with a certain quantity of some sort of shade to protect it from the sun's rays as well as to shelter it from high winds. In certain districts owing to climatic differences there must necessarily be a certain amount of diversity in the kind of trees best suited, as well as regards the density of the shade. To say that coffee in any part of the Province of Coorg, which embraces a climate of wonderful variations considering its area, will grow well and give profitable returns without the help of shade would be a rather rash assertion: but I maintain without the least fear of contradiction that where coffee has been cultivated judiciously under shade in no instance has such cultivation resulted in failure, and I am prepared to go further in maintaining that no place in which coffee has been tried as yet but it would have yielded more or less profit to the grower had the shading of the trees been attended to with care and judgment. Your correspondent's remarks regarding jak as one of the trees suitable for shade are well worthy of notice. There are several other kinds which seem to be as it were universally adapted in this respect. The different varieties of the fig family, for instance, appear to suit equally well in the wet districts as in the dry. In the "bamboo" districts of Coorg we are certainly blessed with good soil, and also with a forcing climate during the greater part of the year, but the long season of drought which we experience between December and April has great drawbacks which are not realized in the "forest" districts of the province; yet, most men prefer to cast in their lot in "the bamboo," and why?—simply because coffee would not pay without having it under shade, hence shade was a *sine qua non* and consequently was studied and handled scientifically. Had the estates opened out on some of the choice bits of our forest land received half the attention bestowed on those neighbouring in bamboo land there would be nothing in the latter to equal them in point of large vigorous trees with close jointed wood alike free from the ravages of "borer" and leaf-disease. I might name another reason why forest land has gone down in public estimation: namely, because of the large tracts of land cleared, which were not fitted from the fact of the exposure being the wrong one, and also the land being unfitted, owing to the nature of the subsoil. Too much sun and too much wind are equally fatal to the constitution of the coffee shrub. It must be borne in mind however, while advocating so strongly the merits of shade, that every other work is to be not neglected: no, by no means. In my humble opinion, timely pruning and handling, keeping down weeds, liberal manuring, and, in short, due regard to be paid to the proper cultivation of the plant, are just as necessary to the welfare of a coffee estate: without these, shade would be of very little avail. With them, it should be the means of at least keeping owners of coffee property in fair circumstances even in these times of low prices. I had intended saying a few words on the merits of the Nalknaad plant and the much discussed subject of leaf-disease, so far as it has affected us, but already this letter has assumed much vaster proportions than was anticipated when commencing.—Yours faithfully,

A "BAMBOO" PLANTER.

CINCHONA ROBUSTA NATURAL BARK 5 YEARS OLD GIVING 6·60 P. C. SULPHATE OF QUININE.

Craig, Haputale, 8th July 1882.

DEAR SIR,—I send you copy analysis of six cinchona trees, "hybrids" or "robustas." These trees were planted in 1872, Hakgala seedlings. Also copy of analysis of six trees, five years old, grown from seed taken from the older trees: the youngsters shame their parents.—Yours truly,

A. McK.

Natural bark.

[The great improvement shown in the bark from trees of the second generation is a good proof of the suitableness of the Haputale climate and soil for these cinchonas. Mr. McKenzie should take care of his best trees, keep the seed separate and watch the further improvement: renewed bark will show a still higher percentage.—ED.]

THE CORK TREE.

Tuesday, July 10th.

DEAR SIR,—"Quercus suber," the cork oak, if planted 45 trees per acre, yielding 150 lb. per tree, would be 6,750 lb. of bark per acre, *i. e.* 3 tons. Can any of your numerous readers kindly inform me—*how cork sells*, and if it is likely to become a drug in the London market, should the supply be largely increased? Whether its cultivation *alone* would necessitate much expense in nurseries, weeding, pruning, labor, etc., and in bringing to saleroom, or if it should be left alone until obtaining maturity, *i. e.* in 15 years. Whether its destruction *then* for tannin would pay? If so, after 1st or 2nd crop, or when to best advantage? Has it failed at a lower altitude than 1,600 feet, other conditions being favourable? Any, or more, information on the subject will be most acceptable.—Believe me, your obedient servant,

NEW PRODUCTS.

A SUCCESSFUL CLEARING OF C. OFFICINALIS FIVE YEARS OLD.

Berar, Bogawantalawa, 11th July.

DEAR SIR,—As there are many who at the present time took upon cinchona officinalis (or, as it is termed in the London market, a "mere annual") as being unsuitable to these coffee districts in the Central Province, I can only say the trouble would be *well* repaid of a visit to the far end of Bogawantalawa.

Last Sunday I spent an afternoon in going over the upper part of Loinorn estate, where there is *literally* without any exaggeration a *forest* of pure officinalis rising five years old.

Although the soil is nothing extraordinary and the drains not particularly close, as generally considered to be necessary, the healthiness of the trees is remarkable, and not one per cent of sickly-looking trees is to be seen. This is equally marked in later plantings of the same variety There are about 15 acres in all of this officinalis planted 6 × 6 in the first instance, and later on supplied between rows and plants, making them 3 × 3 as they now stand.

Undoubtedly the climate where the rainfall is so small and the freeness of the soil coupled with good and careful work can alone account for this great success. I must also mention that Lynford and the adjoining estates bid fair to equal the growth of the clearing above-mentioned, and on Lynford may be seen a field of some 20 acres in extent rising 2 years old, which I have no reason to doubt will be equally good.

In fact, on every side of this most favoured locality may be seen officinalis of all ages looking most promising, in spite of the late winds which have been exceptionally severe. To all interested in the cultivation of this most valuable variety which is so much run down at the present time, the above description, I trust, will be encouraging.—I am, dear sir, yours faithfully,

E. A. C.

HYBRIDS AND CROSSES.

Lindula, 13th July 1882.

DEAR SIR,—In the July number of the *Tropical Agriculturist* just to hand you have an editorial upon a letter from Mr. Gammie headed "What is a Hybrid and What is a Cross?" Mr. Gammie says :—"Will 'X. at the same time tell us where hybrid hares or rabbits are to be seen? He writes as if such were quite common, but I have never either seen or heard of one. There are of course any number of varieties of the common rabbit under domestication, * * * but is there any known instance of the rabbit and hare interbreeding in a state of nature?" You remark upon this :—"We regret to say that we cannot join our good friend in his sceptical queries as to the obtaining of prolific offspring from a union of hares and rabbits," and you give confirmatory extracts from the *Encyclopædia Britannica*, and from *Chambers*. I send you another note on the subject, as every little helps. Could not Mr. W. Smith of Mattakelle tell us whether the hares interbred with the rabbits he used to keep on his patanas?—Yours truly.

KÁROLY FÜRDÖ.

"Of late years a hybrid race of rabbits, bred of a cross between the hare and the rabbit, has been successfully cultivated. These hybrids, singularly enough, and unlike the general rule of hybridization, are able to breed among themselves. The name of *Lepus Darwinii* has been given to this remarkable zoological manufacture of a new species. In Heligoland this kind of rabbit is bred specially for the markets, where it is in high request, and its flesh partakes alike of the best qualities of that of the hare and of the common rabbit."—*Natural History Rambles Underground*, p. 31, 1879, by J. E. Taylor, F. L. S., F. G. S., Editor of *Science Gossip*, &c.

TEA CULTIVATION IN CEYLON :—WHAT CAN BE DONE : FACTS AND FIGURES.

Colombo, July 13th, 1882.

DEAR SIRS,—The export of tea from Ceylon for the current year has increased to 4?2,000 lb., and will probably be 60?,000 by the 30th September. Next year, I think, it will be little short of two millions pounds, and the year after three or four millions, with every prospect of a rapid increase year by year.

I have, as you know, advocated both publicly and privately, the cultivation of tea on abandoned coffee land, and also amongst inferior coffee, especially as an adjunct to coffee and cinchona estates.

Many persons are deterred from adopting the course I have recommended, from a mistaken impression that, unless a large yield per acre is obtained, the cultivation cannot be profitable.

It is with the view of dissipating this idea that I venture to ventilate in your columns a subject, upon which I have given much consideration, and in which I have had some experience.

That the extent of profit on the cultivation of tea in Ceylon as in other countries, depends under equal circumstances, on the yield per acre admits of no question, but, as the cost of production is much less affected by the yield than is generally supposed, it stands to reason that a small yield per acre. from land which has cost a small sum to bring into bearing, may give a larger relative profit than a large yield per acre, from land which has entailed a much larger outlay if the expenses of cultivation, manufacture, and transport to market are equal.

For instance twopence per pound net profit on a tea estate yielding 500 lb. per acre, and costing R200 per acre to bring into bearing, is equal to 20 per cent; whilst two pence per pound on only 250 lb. per acre, on an outlay of R70 per acre, which is the cost of bringing abandoned coffee land into bearing (if it is an adjunct to a coffee estate having water power), is equal to 30 per cent. In saying that the cost of producing and placing tea in the market, is less affected by the acreage yield than is generally imagined, I mean that it costs very little more per pound to lay tea down in Colombo, with a yield of only 250 lb. than it does with one of 500 lb. That this is possible, will be recognised when it is remembered, that after the estate is in bearing, the only items of expenditure in the production of tea, which would affect the cost one way

or another, are weeding and pruning ; and as these do not come to more than seven cents per pound, on a total cost of 33 cents, the difference on a large or small yield would be very slight.

These figures, which will no doubt be criticized closely, are made up as follows :—

Superintendence and contingencies	4c	per lb.
Weeding and pruning	7c	„
Picking green leaf by task work	9c	„
Manufacture where there is a rolling machine	6c	„
Lead-lined tea boxes	5c	„
Transport to Colombo	2c	„
Together	33c	„

I believe these figures will be found to be tolerably correct, but any alteration in them will not affect my argument.

Freight to and charges in England come to about 10c per lb., from which has to be deducted the difference between currency and sterling, say five cents per lb. This would make Ceylon tea cost about ninepence per pound laid down in England, but exclusive of interest on capital invested.

In India, tea estates stand in from five hundred to one thousand rupees per acre, but in Ceylon, I believe, forest land may be planted, and brought into bearing with requisite buildings and machinery, for about two hundred rupees per acre.

As an adjunct to a coffee and cinchona estate, abandoned coffee land may easily be cleared, planted and brought into bearing for R70 per acre, made up as follows :—

Clearing chena land per acre	R10
Holing and lining 3½ ft. by 3½	20
Weeding for two years	24
Re-opening drains, roads and contingencies ...	6
Rolling machine for 100 acres	10
Together ...	R70

It is unnecessary to give any estimate for bringing tea planted amongst coffee in cultivation, as holing and lining are the only items.

In the foregoing estimates I have not included anything for plants : these may cost a few shillings to forty rupees per acre ; whilst one planter may be content to plant seed at stake another planter may prefer to pay R10 per thousand for plants.

I do not recommend any one to plant on abandoned land, which is either steep or has been much washed. With a moist climate, gently sloping or undulating land originally good and planted tolerably close should yield at least 300 lb. per acre.

The benefit to be derived from planting cinchonas amongst tea is too, obvious to necessitate being expatiated upon by me.

The great advantages which Ceylon possesses as a tea producing country are not sufficiently known or recognized. Its climate, situation, facilities of transport, and relative cheapness of labor will enable it to defy the competition of any other country where labor is paid for.

Our climate enables us to crop all the year round, and thus work with a much smaller number of coolies ; it gives us three hundred days to do the same work performed in more northern latitudes in one hundred and twenty days, and our forty years' experience gained in carrying on a cognate industry, enables us to economize labor to the fullest extent. In what other part of the world can virgin forest-land be converted into a productive tea estate, for two hunred rupees per acre, or cultivated on formerly cultivated land at from twenty to seventy rupees per acre ?

A few years hence when Governments discover the inconsistency of preaching doctrines of sobriety to their peoples, and at the same time taxing excessively their non-intoxicating beverages, unalloyed tea may from its cheapness become, as in Eastern Europe, and Northern and Eastern Asia, the chief drink of the masses of the people.

We could not of course compete with China, but for the great number of stiles on the roads from the native villages to the markets, at each of which tolls have to be paid to all engaged in the industry, from the Government downwards.

Japan can no doubt beat us in the race of competition, but we are a long way yet from entering into it.

The chief obstacles in Ceylon to the more extensive cultivation of tea, are first, the poverty of the planting community, secondly our unskilfulness in manufacture. With the number of teachers which are now coming to the island, the necessary knowledge will soon be acquired, and in two or three years hence, there is little doubt our produce will rank in quality, second to none.

When English capitalists have their attention drawn to all the advantages which Ceylon offers, for the profitable employment of capital, in the production of an article the consumption of which is permanent, and increasing and which involves comparatively little outlay and very small risk, I have no doubt money will again flow in the meantime what we have to fear is the loss of labor during the present syncope of coffee planting, which however is a very long way from death, especially if it can be supported in its hours of sickness by cinchona and tea.—Yours truly, C. SHAND.

MR. GORE'S CINCHONA PEELER.

Rookwood, Deltota, 15th July.

DEAR SIR,—Touching cinchona peelers, I think we have a really good thing in Mr. Gore's, and cheap. It was tried here yesterday and yielded 88 lb. of succirubra bark: the coolies were purposely left to themselves, and the day was very wet and windy. Mr. Gore states, in his advertisement, it can harvest 50 lb. of officinalis bark which is a fact. Another recommendation it has is that it can be so easily moved about the field, tied on to any log for use. The intention evidently of the inventor was to screw it down, but this is a mistake: the holes intended for screws come useful to pass the rope through. My notice of this machine (if you are good enough to give it to your readers) may seem somewhat in the way of a puff. What matters ? My object in giving it to you is that I feel we at last have *the perfect* bark harvester for twigs and branches, *diseased* as well as healthy, and cheap and portable withal; but it was tried, and I am sure none can dispute its merits.—Yours faithfully,

C. SPEARMAN ARMSTRONG.

[In publishing this testimony, we may say that we ought ere now to have published a very favourable account we received of Mr. Rae's machine ; and there is also the Norwood invention doing wonders; so that our cinchona planters are surely well off now.—ED.]

CINCHONA OFFICINALIS.

Bogawantalawa, July 17th, 1882.

DEAR SIR,—It is refreshing to see some one take up his pen in defence of the much-maligned *C. officinalis*, for during the last few months the V. A.'s who run it down as almost a curse to the country have had it all their own way, and have been allowed to condemn and vilify poor officinalis unchecked and unchallenged. A visit to the Agrapatana end of Dimbula should. I think, be sufficient to prove the fallacy of their statements with reference to the fearful mortality *C. officinalis* is said to be heir to, and, although this variety of cinchona is notoriously sensitive to cold wet and "clayey" soils, surely this is

no reason why it should be condemned in the wholesale and sweeping manner it has been. In my belief, officinalis has its proper zone in Ceylon in point of climate and elevation, and when this is found it is a very poor soil that will not grow it with greater or less degree of success.—Yours faithfully, HYBRID.

[Not far from Loinorn, we learn, there is an abandoned plantation once covered with young officinalis plants which failed to grow up: now here is the chance for the wise men of Dikoya to examine and report on the success and failure: the wherefore and why.—ED.]

THE CASTOR-OIL PLANT AS A FLY-KILLER.—Observations made by M. Rafford, a member of the Société d'Horticulture at Limoges, show that, a castor-oil plant having been placed in a room infested with flies, they disappeared as by enchantment. Wishing to find the cause, he soon found under the castor-oil plant a number of dead flies, and a large number of bodies had remained clinging to the under-surface of the leaves. It would, therefore, appear that the leaves of the castor-oil plant give out an essential oil, or some toxic principle which possesses very strong insecticide qualities. Castor-oil plants are in France very much used as ornamental plants in rooms, and they resist very well variations of atmosphere and temperature. As the castor-oil plant is very much grown and cultivated in all gardens, the *Journal d'Agriculture* points out that it would be worth while to dry decoctions of the leaves to destroy the green flies and other insects which in summer are so destructive to plants and fruit-trees. Anyhow, M. Rafford's observations meant that trial should be made of the properties of the castor-oil plant both for the destruction of flies in dwellings and of other troublesome insects.—*British Medical Journal.* [A correspondent, on p.908 vol. I of the *T. A.*, stated that his experience was quite contrary to that given above: he found the castor-oil plant peculiarly subject to the attacks of insects.—ED.]

IRRIGATION CANALS IN INDIA most people believe th be unmitigated blessings. A writer in the new and ably conducted *Indigo Planters' Gazette*, is of a different opinion as witness the following extract:—

"Where ignorance is bliss 'tis folly to be wise" is evidently the motto adopted by the authorities in the Nort-West Provinces and the Punjab, in the management of their canals. Because canals have succeeded with admirable results in Southern Europe, Egypt, and parts of Madras, it has been argued by the authorities in India that they must, as a natural consequence, succeed in the arid plains of the North-West Provinces and the Punjab. The west winds howl; the atmosphere is one of the driest in the world; the rainfall is partial and light, and therefore (argue our authorities) all that is wanted to turn the Northern Indian plains from a desert to a garden is a plentiful supply of canal water. No heed is taken of the fact that the howling west winds, and the dry atmosphere of these provinces constitute a "sucker" of irresistible power, which, through time, will lay waste the surface of the fields with salts raised by excessive capillary action. The laws of nature are ignored, and the Strachey and Hunterian school of administrators, with all the influential newspapers of India and England at their back, having settled that irrigation is the chief panacea for the evils arising from excessive drought, have covered Northern India with a network of high level canals, which, if they continue to work as they are worked at present, will, before many years are over convert a magnificent wheat-producing country into a saline waste.

There can no doubt that the saline efflorescence, locally "reh," is promoted by irrigation and is a terrible curse. But surely some chemical agent, cheap as well as effective, can be found to counteract it, or convert it into a valuable compound.

CINCHONA *vs.* TEA.—We wonder that planters in the hill districts of India are not turning their attention more than would seem to be the case to cinchona cultivation. There is no reason why, in the Darjeeling district, the present area could not be increased a hundred fold, while many parts of the Kangra Valley should be equally suitable in point of climate. In Ceylon they are taking up cinchona in earnest, and there is no reason why we should not do the same. In fact there is every reason why we should. —*Indian Tea Gazette.* [The success of cinchona in the sheltered valleys below Darjiling has been proved; but the Kangra Valley? We were under the impression that trials in the northern Himalayas had resulted in entire failure. Tea will stand snow and some frost; cinchona will not.—ED.]

THE NILGIRI POTATO CROP.—The coming potato crop promises to be a comparatively good one. There has been considerable extension in the growth of potatoes in the district, but the disease has not yet disappeared. A disregard in the selection of seed is still apparent, and the gratuitous distribution by Government has had no preceptible influence on the crops; in fact, we have seen a good deal of diseased seed sent out of the gardens. The market price of Nilgiri potatoes is prohibitive. The finer sorts selling for 2 and 2½ rupees a maund of twenty-five pounds, while for ordinary kinds 1¼ and 1½ rupee are the ruling rates. This scarcity has induced the importation of Bangalore potatoes, which are brought and sold here for about the same as inferior local sorts, while the quality and flavour are much below. Many places on these hills are admirably adapted for the growth of the potato, which at present is left to a careless class of growers, who do not care to improve the quality or the cropping power of the tuber. The demand for Niligiri potato, especially for the Kulhutty, which has long since ceased to be the fine tuber it once was, is great in the plains, and every market day sees return bandies carrying away tons of this food which we can ill spare.—*Madras Mail.*

GIANT GRASS.—Last May, Messrs. Klunder and Co., Soerabaya, wrote to the Madras Government to say that they had forwarded a copy of instructions for cultivating "giant grass." This letter was communicated to the Superintendent, Government Farms, for remarks. The instructions referred to were, however: not received. The Superintendent reported that he had no personal knowledge of the grass in question:—"It is not an Asiatic species, but is indigenous in the region of country lying to the west of the Missouri River, United States, where it is found widely spread. Referring to this grass, in his report for the year 1870, the United States Commissioner of Agriculture wrote, 'The early pioneer, however, has already learned how soon the good native grasses are destroyed by the clipping and treading of domestic animals, and he sees with regret their places immediately occupied. . . *Panicum cappillars, Panicum sanguinale*, &c., &c., worthless weeds and grasses that occupy the soil to the exculsion of every profitable production.' From this quotation, it would appear that the grass has not a good reputation in the country where it is indigenous. Of course, it is possible the grass may have since been improved by undergoing special cultivation and treatment. I cannot, however, recommend that Government should incur any expense in endeavouring to introduce the grass. At the same time, it may be worth while to get some seed and try it here. This I can readily arrange to carry out. I will also write to the Director of Botanical Gardens and plantations, Batavia, Java, with whom I am in correspondence and who, I know, will gladly afford any information in his power about the grass."—*Madras Times.*

FIBRES.—Mr. Egerton calls attention to the fibre known as "caraguatá ibera," a *Bromelacia*, which is something like the pine-apple plant, and which is very abundant in Paraguay, the Misiones, and the Chaco. It is very long and silky, has long been used by the Indians, and much money has been spent in endeavours to find some practical machine for the economical preparing of the fibre. The desired result has at length, after a long series of experiments, been attained by a French machine, invented for the purpose, which has been set up not very far from Asuncion—the process being a simple one, without previous maceration. The fibre, Mr. Egerton adds, will become an extremely important article of commerce, and should compete with advantage against jute.—*British Trade Journal.*

MEXICAN COFFEE.—The *Anglo-Brazilian Times* refers to a successful effort made by Messrs. Steele, of Rio de Janeiro, to grow the Mexican variety of the coffee plant on their plantation in that province. These gentlemen, we are informed, had exhibited on the Rio exchange laden branches raised from Mexican seed, and they are said to have attracted "much attention from the regularity of the clusters and ripening of the berries." Our contemporary remarks:—"Messrs. Steele are to be congratulated on the public spirit which has led them to obtain the seed and grow it, and to afford persons interested in the great industry of this country an opportunity of examining in full fruit and leaf a coffee of such precious qualities and high estimation."—*South American Journal.* [It might be worth while trying the seed of this Mexican variety in Ceylon.—ED.]

CEYLON TEA.—We observe, our townsman, Mr. Maclaren, of Messrs. William Moran & Co., has been laid hold of on his way through Colombo, and induced to look at a large number of Ceylon tea samples. This is one of the penalties of greatness, and, as Mr. Maclaren has made a name for himself in connection with tea, he must not be surprized if he be interviewed in this manner. He was able to give an encouraging opinion of their produce, which must have been very satisfactory to the island planters. We are told he valued none of the samples under 1s 2d, and some as high as 2s 4d. If none were under 1s 2d, we imagine they could not have been a fair average assortment of samples. They must have been only high-class teas; at any rate, as the result of this examination, we shall expect Ceylon to take a higher rank in Mincing Lane this year than she has hitherto done. We are afraid that the mistake made by Ceylon is in planting out tea as an appanage to a coffee plantation leaving its cultivation and manufacture to the coffee, manager and his establishment. This will not dorh treatment of the two plants being so diverse, in der to give the tea anything like fair play, it must have its own trained establishment. The former mode may be excusable, when only a few acres are planted for experimental purposes, but, if Ceylon wishes to take her place among tea producing districts, she must grow and manufacture her crop on more intelligent principles. Mr. Maclaren complained of over and under fermentation, and of over-firing. Fermentation being one of the most important processes in manufacturing would seem not to have received that attention it deserves. These facts all go to prove what we have said; that the growing and manufacturing of tea must be superintended by gentlemen who have given attention to the subjects, and not by coffee planters whose experience has been in another direction.—*Indigo Planters' Gazette.* [But there is nothing in the world to prevent an intelligent coffee-planter mastering the mysteries of tea manufacture. Many have qualified themselves and others are learning. Unhappily, on a large number of coffee estates, the quantity of coffee recently produced has not been such as to demand the exclusive attentionof superintendents.—ED.]

RICE.—According to the United State Censes of 1880 the three states of South Carolina, Georgia and Louisiana produced almost the entire rice crop of 1879, their respective crops being, in round numbers, 52, 25, and 23 million pounds. The average yield per acre was 725 pounds in Georgia, 664 pounds in South Carolina, and 552 pounds in Louisiana. Some few single counties in these states exhibited an average yield of 1,000 pounds per acre, but the areas of such an average were small.—*Rio News.*

THE IPECACUANHA PLANT.—Major J. C. Walker, Conservator of Forests, reports that the two Ipecacuanha (*Cephaelis Ipecacuanha*) plants received in 1870 never attained sufficient growth to propagate from; they flowered, but failed to ripen fruit, and died in 1873. Some plants were subsequently sent by Mr. Jamieson for experiment at Nilambur with identical results. The climate of Nilambur is evidently not suitable. The Government look especially to the Conservator of Forests to take measures for the successful cultivation of the Ipecacuanha plant, which in its habitat is reported to grow in a damp atmosphere, under the shade of woods, and exposed to full tropical heat. The Conservator is to make enquiries from all his subordinates working on or under the western face of the ghats, as to the places fulfilling the conditions mentioned above.—*M. Mail.*

COCOA.—Mr. Morris, in the course of his lecture, alluded to what depreciates cocoa in the British market—namely, the practice of washing and drying it in the sun. That is just the way with us Jamaicans—generally overdoing things. What is it that sometimes hinders our coffee from equalling the Mocha? Just that same washing (and pulping). We are, in fact, too neat, where neatness is out of place,* and not sufficiently so where neatness is in order—as in the practice of packing oranges in old, flour and biscuit barrels. The sensible Arabs dry their coffee in the pulp, just as we have seen done by such of our peasantry who grow a little coffee for their own use. This preserves the aroma of the berry, but the process of pulping or "hulling," as the Yankees would term it—is just a little more troublesome. Besides, the adoption of the process of drying in the pulp would necessitate the alteration of the "hulling" machinery to meet the new conditions, and our coffee planters as well as our sugar growers and manufacturers, are like the people of China, incurably conservative in their methods and habits.—*Gall's News Letter.*

THE VALUABLE AMERICAN TIMBER, belonging to the family of the Asclepiades, and regarding which information was quoted on page 148, Vol. I., of the *Tropical Agriculturist*, is thus noticed in the *South American Journal* under the news from Buenos Ayres:—

A large European steamer had ascended the rivers to the Gran Chaco, with the object of loading quebracho sleepers. The incident is one of a very suggestive character. It should be known that the Argentine wealth in timber in the Gran Chaco region is practically inexhaustible, and that nowhere in the world is there to be found better or more durable wood for railway sleepers than grows in that part of the River Plate. Indeed, the quebracho colorado is said to be "superior to iron." The facts are thus stated by the Rosario correspondent of the *Buenos Ayres Standard*:—

"It is worthy of mention that the steamship 'Maria,' of the Marseilles and Genoa line, of 1,200 tons, has gone up to the Gran Chaco to load quebracho sleepers for Europe. This is the largest merchant craft that has up to the present time gone so far up the Paraua. It is impossible to doubt the importance of the object of this expedition. It would appear that our quebracho wood,

* What Mr. Morris condemned, however, was want of neatness.—ED.

HOW TO WATER HANGING BASKETS.—Hanging baskets require frequent watering, to accomplish which, with due regard for the carpet beneath, they must commonly be taken down from their perches and then suspended elsewhere to dry. This trouble may be avoided by a sample and inexpensive device. Fill a bottle with water, into which insert the ends of two pieces of yarn, permitting the other end of each piece to hang down outside the bottle. The bottle should be suspended just above the basket and the water allowed to drip, which will follow in sufficient quantities to keep the earth moist.—*Illustrated Sydney News.*

AGRICULTURAL COMPANY OF MAURITIUS.—Inclusive of £5,422 gained by exchange on funds remitted to Mauritius, the net profits of the Agricultural Company of Mauritius (Limited) for the year ended March 31st, were £18,012 which was increased to 18,251, by the addition of a small sum brought forward. The directors have carried £3,000 to the reserved fund general account which is thereby raised to £36,038, and £10,000 to the reserved fund exchange account, which stands at £40,000. They now propose a dividend of 1s 6d. per share, making a total return of 3s per share, or 15 per cent., for the year; and further recommend a bonus of 1s. per share, or at the rate of 5 per cent. The balance to be carried forward is £251.—*Overland Mail.*

GOLD IN CEYLON.—Interest in our quarts reefs will be revived by intelligence received from England. Samples amounting to one-fourth of a ton of quartz from Rangboda estate, in the Ramboda district, has been found, on analyses by the Assayer to the Bank of England, to contain as much as two ounces of gold to the ton. A further large sample from the same locality is now on its way home, and, if the test prove equally satisfactory, no time will be lost in commencing mining operations. The enterprise could not be begun under better auspices, and we have not the slightest doubt that when capitalists realize the facilities of ready transport and cheap reliable labour as well as of healthy climate which exist in Ceylon, that not alone in respect of gold-mining will British capital once again begin freely to seek investment in the country. Our new products—tea, cinchona, cocoa, rubbers, &c.—challenge attention on all sides.

MR. SCHROTTKY AND BLIGHT.—We had occasion some years ago to dispute with Mr. Schrottky regarding his diagnosis of spider blight—and for this reason: that he based his conclusions on mere theory, and not from a practical experience on the spot (in tea gardens) of the nature and effects of blight. Since then this gentleman has spent a considerable time in Ceylon, endeavouring to grapple with the dread *Hemileia Vastatrix*. He appears to have gone to work in a most practical manner, by visiting and residing for some time at different coffee estates. This is the right plan; and, whether he has succeeded or not in finding a remedy for the coffee disease, he has gone the best way to effect this, and only thanks are due to him. Let him try the same plan in India in reference to red spider, and he may earn the gratitude of all tea planters. The man who should discover a remedy for this pest could hardly be over rewarded. We advocated, years ago, the employment of a State entomologist for this purpose. A movement was made, but it ended in nothing, because it was not sufficiently followed up. It surprizes us that in a matter of such vital interest to the tea industry, a subscription *list* is not started so as to permit of the best services of a scientist being secured.—*Indian Tea Gazette.* [What has happened to us in Ceylon in regard to coffee fungus would probably be repeated in India in regard to red spider and other insect pests. The whole "life-history" of the insects would be detailed in elaborate reports, but no cure would be indicated, only remediable measures already known, but not availed of, because too expensive.—ED.]

LUMINOUS PAINT ON PLANTATIONS.—In a pamphlet giving an account of the uses to which Balman's patent luminous paint can be applied, we find the following paragraph:—

In those countries having wide tracts of land without roads, large stones may be painted and placed a mile apart, so that the shortest tract is denoted on dark nights—through plantations, luminous arrows pointing the way, can be painted on the trunks of trees, and in those countries where towns are not lighted with gas, all the house-door Nos. and street names, if luminous, render great benefit for the better administration of the public service.

VEGETABLE PARASITES.—The commonly received opinion concerning vegetable parasites is that they attack their victims. But S. T. Fergus, in *Coulter's Gazette* (*Gard. Chron.* Feb. 4), gives the beech tree credit for a benevolence which quite upsets preconceived ideas on this point. He says, concerning a root parasite known as beech drops or cancer root, *Epiphegus virginiana*:—"The beech root, on being touched by the parasite, sends a branch or branch-like growth into the latter, through which all its nourishment is carried, causing the death of the root from this point to the end, if not too large, while that above flourishes despite the drain of the parasite. If, however, the root is large, and there is substance enough after the parasite is supplied, it will live, but will be retarded in its growth."—*Pharmaceutical Journal.*

NEW PRODCTUS.—We are glad to learn that the proprietor of Damboolagalla and Petikande plantations in Matale East, has just invested in 500 acres of crown land in the Yatiyantota district with the view of cultivating new products, chiefly tea. Mr. J. H. Young, during a long connection with Ceylon, extending over nearly 40 years as proprietor of coffee and cinnamon plantations, has had no occasion to speak otherwise than well of the colony in which his capital was invested, and we trust a full measure of success will attend the new venture he has now to embark in. All the accounts we receive of the prospects of tea in the districts between Awisawella and Gampola continue to be most promising. It is reported that the Mariawatte tea estate near Gampola has been leased by Mr. Wm. Cameron (tea planter from Assam) for R6,000 per annum: we cannot vouch for the rent being correctly quoted. The estate consists of 107 acres planted chiefly with tea, but with some cocoa and cardamons.

INDIAN TEA.—The following figures, showing the growth of the Indian tea trade during the last eleven years, from the Custom-house records, are taken from the second annual report of the Indian Tea Districts Association. The increase in deliveries is 360 per cent.

Amounts imported into this country, and the amounts cleared for home consumption.

	Imports.	Deliveries.
1870	13,148,168	13,472,800
1871	15,351,672	13,560,120
1872	16,924,030	16,272,060
1873	18,424,077	18,392,061
1874	17,377,976	17,756,640
1875	25,605,132	23,273,994
1876	29,383,788	26,733,820
1877	31,883,310	28,011,600
1878	36,007,140	36,766,460
1879	38,483,684	35,243,194
1880	44,010,554	43,500,000
1881	45,765,000	48,500,000

Since 1877 there has been an increase in the consumption of Indian tea of 20½ million lb., while during the same period there has been a decrease in the consumption of China tea of 9 million lb.—*Journal of the Society of Arts.*

GERMS AND BACTERIA.

The part formerly played by electricity seems now likely to be assigned to Bacteria. A few years ago, when any new or strange phenomenon was made known, a ready explanation was found in the word electricity, and most people of an unscientific turn of mind complacently went on their way without giving a longer thought to the matter. Now-a-days "Germs" and Bacteria are accepted by many as the causes of various phenomena with just as little real enquiry. It is not that electricity is really any less potent than before, but the potency of Bacteria is a new revelation. Although the word is getting common, and the effects more and more recognised, the definition of Bacteria is not yet settled, their place in organised Nature not known beyond dispute, their life-history by no means fully unravelled. It must suffice for us here to remind the reader that these Bacteria are, in all probability, plants; they are certainly of extreme minuteness, and of extreme simplicity of structure, and they are probably mere transitory stages of some more perfect organism. Under certain circumstances they exist in prodigious numbers, and, under certain circumstances, they bring about changes and diseases in the unfortunate animals or plants into which they gain an introduction. It is natural to suppose that these minute germs are but the accompaniments of fermentation and putrefaction—effects, not causes, and this may be so in some instances. In other cases it has been proved to demonstration that certain changes and diseased conditions arise when they are introduced, and do not arise when by various means their entrance is prevented, or their activity destroyed. By experiments on animals, amongst other means, these facts have been established, and not only this, the means of prevention have been found. One hundred and fifty thousand horses, cattle, and sheep have now been vaccinated by M. Pasteur and his disciples, and the success in preventing the access of splenic fever, if not absolute, is yet so large as amply to prove the greatness of the benefit conferred. As we have already referred to this matter, explained the *rationale* of the process, and recorded the already vast beneficial results, we need not again enter into details further than to remind cultivators of fruit trees that they have their concern in the matter, since it has been asserted—though the statement requires confirmation—that a particular form of canker in Apple trees is caused by the presence of these Bacteria.

It is our purpose, however, now to once again call attention to an aspect of the matter in which cultivators, whether farmers or gardeners have the deepest concern—we mean the existence of these agents in the soil and the work they do in it. In some remarks contributed to these columns under the title *Horæ Hortulanæ* it was shown by the writer how the difference between the inert "dead soil" and the "live soil" might be accounted for by the presence of these wonder-working agents in the one and their absence in the latter. Sterile poor soil may and often does owe its sterility, not to any real deficiency of plant food in the soil, but to the absence of those go-betweens whose office it is to convert the insoluble to the soluble, the useless to the useful. The food may exist in abundance, but for want of proper cooks it may be of no avail to the hungry plants. The actual quantities of certain ingredients taken from the soil by plants are often so small that it rarely happens that a soil does not prove on analysis to contain ten times —a thousand times—more than what would be required for the plants growing upon it. The analysis of a soil by a chemist is, however, one thing, the analysis of the same soil by a plant is quite another. Most soils, for instance, contain as much potash as the plant is likely to require, and yet it is not always yielded up to the plant in sufficient quantities, as is proved by the beneficial results of the application of potash manures. We do not yet know whether Bacteria play any part in the supply of potash in an available form, but quite apart from potash it is certain that we often actually pay for large quantities of fertilisers when there is a more than sufficient supply already in the soil could we but make them available. We do not lay this down as absolute truth, of universal application at all times and seasons: we are far too ignorant as yet to deal in dogmas; still what we have said is, we believe, substantially a correct illustration of a general truth, and represents, so far as it goes, the present state of science on this matter.

The latest publications on the subject are those of Mr. Warington, who lately addressed the Society of Arts on the subject. Nitre, or saltpetre—in chemical language potassic nitrate, or nitrate of potash—is, as has long been known, formed in the soil in large quantities in certain hot countries, and it was ascertained by chemists that this production of potassic nitrate was due to the combination of nitric acid and potosh. The nitric acid necessary to form the combination does not exist ready-made in the soil, but is derived from ammonia. Now, when oxygen is added to ammonia (a compound of hydrogen and nitrogen) the ammonia is oxidised, as it is said, and the ammonia becomes converted into nitric acid. Thus much was known for certain, but until the last few years it was not known what brought about the oxidation of the ammonia. Two French chemists, MM. Schlœsing and Muntz, in 1877, proved that the formation of nitre in the soil was due to the action of a living ferment. Mr. Warington investigated the subject for himself in Mr. Lawes' Laboratory at Rothamsted, and has been enabled to confirm fully the theory just mentioned, and the proof was afforded by the same means as those we have before alluded to. When access of germs was prevented, no nitrification took place; when they were allowed ingress, or when they were purposely added, then the process began: so that in the inorganic lifeless soil, as well as in the organic living plant or animal, these humble organisms play a part of first-rate importance. Mr. Warington having succeeded in producing nitrification at will, proceeds to show how the process may be carried on on a large scale for commercial purposes; and a perusal of his paper among other things suggests the possibility of making our own nitrate of soda, and of thus reducing the cost of this valuable manure.

Another very important aspect of the case is touched on by Mr. Warington; we allude to the purification of sewage. The purification of sewage by the soil depends upon one or more of the following causes:—1, simple filtration; 2, on the precipitation and retention by the soil of ammonia, &c., previously in solution; and lastly, and especially, by the oxidation of the ammonia and of organic matter by the agency of living organisms (Bacteria). These organisms are abundantly present in surface soils, but are probably absent, or nearly so, from sub-soils, but sewage and farmyard manure contain the organisms necessary for their own destruction, and the supply of the plant with food. The amount of nitrates formed in the soil, and which are so important to plants—inasmuch as it is through them that vegetation derives its nitrogen—is very large, and has formed the subject of special investigation at Rothamsted. There the rainfall, the amount of drainage water per acre, down to a depth of 60 inches, and the quantity of nitrogen in that water have been determined for the last five years, the general result being that nitrates are seen to be produced in large quantities even in unmanured fallow soil, more especially in the hot autumn months; on the other hand, during the rainy months a large quantity of the nitrates will be washed away, to the detriment of the soil's fertility. The growth of any

crop on the land checks this outpour of nitrates, first because much more water is evaporated from the soil and the plants together than from the bare soil, so that the amount in the drainage will be diminished, and because the roots greedily take up the nitrate from the soil, so that the drainage waters collected from a Wheat field in June—July were found to contain little or no nitrates—all, or nearly all, had been taken up by the plant. The Wheat, however, ceases to take up nitrates after its season of growth is over, and there is, therefore, the risk, the certainty rather, that the remaining nitrogen will be drained out from the soil. But in the case of root crops the growing period goes on much longer, so that the roots get the benefit of the summer production of nitrates and obviate much of the loss and waste in the autumn. Permanent pasture, where there is a crop on the land all the year round, obviates the loss of nitrates even more effectually. With reference to this waste of nitrogen (valued at about 1s. for 7 lb.) the practical question is, whether it is cheaper for the cultivator to buy nitrates at a high price (the present value is £16 a ton) or to take more or less expensive means to prevent the waste.

It may, however, be within the bounds of possibility that even as we have now the means of effecting oxidation and consequent solubility, so chemists and microscopists may some day be able to tell us how to reverse the process. There are many kinds of Bacteria, and we already know that their life habits are very varied. Mr. Warington himself tells us that while one will ensure the formation of nitric acid, another will only form nitrous acid, an acid containing a less proportion of oxygen than the nitric. There is, then, nothing inconceivable in the suggestion that as some of these organisms are now known to act as cooks and dish up good food to the plants, others may be found to stop or counteract the process. When we have reached that happy stage we shall turn on the nitrogen just when we want it, and turn it off when it is of no more service, just as we have done for years in the case of gas, and we are now doing with the electric light.—*Gardeners' Chronicle.*

THE MUNGOOSE AND RATS ON SUGAR, COCOA AND COFFEE ESTATES IN JAMAICA.

While collecting information for a report on the agricultural products of Jamaica, I was lately led to investigate the results of the introduction of the mungoose (Herpestes ichneumon) into the island for the purpose of destroying the plague of rats, which have always more or less infested sugar estates and caused considerable loss by their ubiquitous depredations. As a consequence, rat-catching has been an important item in all sugar estate expenses not only in Jamaica, but in all the West Indian islands, and for the last two hundred years numerous suggestions have been made to cope with an evil which, in spite of rat-catchers, dogs, traps, baits, and poisons, has remained as great as ever.

The rat-catchers on estates are mostly Africans (negroes), who pursue their calling accompanied by a troop of dogs, and use traps of a very primitive fashion. These consist of a bow made of tough wood, with a small basket at one end to hold the bait, and just large enough to admit a rat's head. The string, attached to the bow, is formed into a loop inside the basket, and held ready for action by a small peg, on which the bait is fixed. The rat, on touching the bait, loosens the attachment of the string, which suddenly tightens round its throat and kills it. Besides traps, poisons prepared from phosphorus are largely used.

The common brown and black rats of Europe, introduced, no doubt, by ships, are common everywhere; but the most destructive to the sugar cane is the "cane-piece rat," which Gosse has named Mus sacchari-vorus—distinguished by its large size and white belly' a truly formidable creature (drawn by Robinson in his M S. volumes, iv., 13), measuring 20in. in length, of which the tail measures one-half. This rat is also known as the "Charley Price rat," from an impression —proved, however, to be erroneous—that it was introduced by Sir Charles Price for the purpose of destroying the black and brown rats. Naturally, one of the first thoughts of an Englishman plagued by rats, and beyond the power of cats and dogs, would be the introduction and naturalisation of the European ferret.* It appears, however, that the ferrets when introduced were rendered useless by their inability to overcome the attacks of the Chigoe flea, which infests the lowlands and becomes a serious pest to most imported animals. "Under these circumstances, Sir Charles Price bethought him that, if he could find an animal in the country of the Chigo, corresponding to the weasel of Europe, he would accomplish the naturalisation of a rat destroyer with instincts capable of counteracting the plague of the parasitical insect. He accordingly procured something from South America, that, in the eyes of the negroes, had strong rat characteristics, but which was no rat. It was of large size. Several were set at large about the house at the Decoy in St. Mary's and at Worthy Park, to establish themselves how they might. It would seem that nothing came of the scheme, for no animal allied to the musteline group quadrupeds has been found in the colony."† The appearance of the large "cane-piece rat" in the island about this same time was no doubt connected by the natives with the animals introduced by Sir Charles Price, hence his name remains associated with the rat instead of its destroyer.

The introducer of the native ant of Cuba (Formica omnivora) was more fortunate. This is said to have been Thomas Raffles, who, in 1762, brought over this formidable hymenopteron to prey on the young rats; and, strange as it may appear, the "Tom Raffle ant" has remained to this day a firm friend to the sugar planter and a foe to all pests of rats and vermin.‡ To aid the "Raffle ant," another foe to rats was adopted in the "Agua toad"—an enormous South American amphibian, some seven inches from the muzzle to the coccygeal extremity, and as broad as long. This was introduced by Mr Anthony Davis in 1844. These gigantic toads had been considered in Martinique and Barbadoes very important auxiliaries to the planter by their pursuit and destruction of young rats. They had no doubt been introduced in the first instance from Cayenne and the intertropical parts of South America, where they are said to be indigenous, and to abound in great numbers. The dispersal of these strange animals in Jamaica caused at first considerable commotion. The oldest inhabitant never heard such hoarse bellowings from the ponds and pastures as suddenly saluted their ears when this "Bull frog" became common. Its note, to use the words of the late Mr Richard Hill, is a "loud sort of modulated snoring noise" and he evidently thought little of it as a rat catcher, for he adds, "they are now (1847) eradically established among us, and are to be added to the miscalculating delusions which gave us 'big rats' to devour 'little rats,' and the ant of Cuba to rid us of the accumulated

* Although cats have been introduced and encouraged on estates, it appears that they have not contributed largely to diminish the plague of rats. There is an impression in the island, which I give for what it is wor h, that the negroes are addicted to eating cats, and thus frustrate the efforts of the planter; but whether from choice or as an antidote to Obeahism is not stated.

† Gosse "Naturalist's Sojourn in Jamaica," 1851, p. 447.

‡ In some districts where specially abundant, the "Raffle ant" has been known to attack the young of both cats and dogs, and to severely injure them, especially in the eyes. Calves have also been similarly affected.

pest of rats and vermin, and to become a more intolerable scourge than all the other plagues put together." *

It appeared, however, that both the Raffle ant and the Agua toad had had their day, for up to 1872 the rat pest continued as great as ever. In some of the moister parishes of the island depredations by rats were estimated to cause the loss of nearly one-fifth the produce of a large estate, while the cost of rate catching, poison, &c., amounted to more than £200 per annum.

It would be almost impossible to estimate, with any degree of certainty, the annual loss caused by rats on sugar estates; for, although planters in nearly all cases could give the number of cartloads of rat-eaten canes ground for the still house, the fact that these canes give a return in rum somewhat lessens the loss.

It is, I know currently reported that some estates in the Swift River Valley (Portland), such as Paradise, Eden, Elysium, and Shrewsbury were actually abandoned, owing to the destructive depredations, of rats. This may not have actually been the case. It is a fact, however, that portions of estates and cane pieces bordering on woods and near rocks, affording shelter to rats, have been finally abandoned on account of their depredations; and even in the case of whole estates, "the damage caused by rats has no doubt been one of those large leaks that has helped to sink them."

From a careful series of returns received from planters in all parts of the island, I am led to believe that the loss caused by rats in rat-eaten canes, up to a recent date, could not be less than £50,000 per annum; while the expenses incurred in rat-catching, rebuilding walls pulled down to catch rats, poison baits, and rat-traps, would reach nearly £5,000 per annum. This, however, only applies to sugar estates. Cane pieces cultivated by settlers, coffee, cacao, coconuts, corn, sweet potatoes, arrowroot, fruits, peas, vegetables, and numerous other crops, appear to have suffered equally from depredations by rats, so that the total loss caused by rats in Jamaica, apart from the discouragement which they have caused to many minor industries, might very safely be estimated at not less than £100,000 per annum.

As examples of the distribution of rats and the destruction caused by them in the island, the proprietor of an estate in Trelawny informs me that "the annual number of rats destroyed and paid for on one estate was over 20,000 at the rate of one penny per head, exclusive of what was destroyed by poison and dogs." Another in Portland writes: "I lost fully 20 to 25 per cent of the entire sugar crop by the ravages of rats, and could never grow corn, sweet potatoes, or peas. The cost of catching rats was over £200 per annum." A large proprietor in St. James's reports that he paid in a district not remarkable for the depredations of rats, on an average £70 per annum for rat-catching, and the destruction of canes by rats may be moderately estimated at £200 per annum." Another reports: "On this estate we lost frightfully by rats; fully one-third of the crops were often destroyed."

With these facts before us, it will not be a matter of surprise to learn that the rat question has continually cropped up and pressed itself with more or less vigour upon the proprietors of all estates and especially in the moister districts. The "Tom Raffle ant" had either lost its initial vigour, or had gradually disappeared from districts in which it had proved of service.† The "Agua toad," if it ever was of service, was quite unequal to the formidable task of cleaning out some hundreds of thousands "cane-piece rats." A new rat enemy was therefore in urgent request, and the mungoose was thought of.

Among the earliest importers of the mungoose into Jamaica were the Hon. William Vickers, Westmoreland; Mr. De B. Spencer Heaven, of Ramble; Mr. Wm. Bryce Watson, of London; Hon. J. W. Fisher, Mahogany Hall; Mr. Shortridge, of Hollands Estate; and Mr. Burgess, of Mount Eagle. Most of the animals introduced by these gentlemen were, however, obtained from London, and having been bred in captivity they were to use the words of one of the introducers, "literally afraid of a rat." The first importer of the mungoose direct from India appears to have been Mr. Wm. Bancroft Espeut, of Spring Garden Estate, Portland, who, by the interest of Government, with the aid of Mr. Anderson, Agent General of Immigration in India, obtained four males and five females by the cooly ship "Merchantman" in March 1872. Mr. Espeut paid £9 for their expenses in transit, and at once turned them out on different portions of his estate. From these nine animals nearly, if not quite, all the mungooses in the island at the present time have been obtained. Hence, among the natives, the mungoose is becoming known as "Massa Espeut ratta," just as the animals supposed to have been introduced by Sir Charles Price were called "Massa Price ratta."

The negroes in the neighbourhood of Spring Garden Estate appear to have caught and sold thousands of mungooses to planters in other parishes. One who went actively into the trade is said to have received over £300 for animals supplied to estates in other parts of the island.* All these were doubtless the progeny of the nine introduced by Mr Espeut in 1872. Their powers of reproduction must therefore be very great. They are now firmly established in the neighbourhood of Kingston and in every parish in the island; and even in the mountains at elevations from 5,000ft. to 6,000ft., with a minimum temperature of 45° Fahr., they are becoming quite common. That they can swim and dive with great facility has often been noticed and thus streams and lagoons offer no hindrance to their dispersal. After just ten years' experience with the mungoose in Jamaica, it is an interesting question both for the sugar planter and the naturalist to discuss, What are the practical results of the experiment?

The introduction and complete naturalisation of an animal possessing such strong predatory habits and remarkable powers of reproduction as the mungoose must have an important influence on all indigenous and introduced animals capable of being affected by it. As is well known, the mungoose, although shaped like a weasel, belongs to the civet-cat family (Viverridæ), and its disposition is as sanguinary as its habits are predatory. Its natural food consists of birds, snakes, lizards, rats, mice, and last but not least, the eggs of both birds and reptiles. In India the destruction which it often causes amongst poultry is well compensated by the incessant war which it wages against snakes and vermin. Even the lethal cobra falls a victim to the agility of the mungoose, which, according to eastern tradtion, is said to possess an antidote, by means of which it can withstand the venom of the most deadly reptile. This would represent a total saving to the island of nearly £45,000 per annum.

For sugar estates, the rat question appears, for the present at least, to have been fully solved. With regard to other industries, the question is not so clear, nor, perhaps at first sight, so satisfactory.

* The "Bull frogs" (as they are called by the negroes) are said to commit depredations on ducklings in ponds, and to be terrible enemies to beehives. I can well understand that to a confirmed insectivore like a toad, our stingless and easible accessible bee must be a veritable *bonne bouche*.

† On this point a correspondent remarks: "Formerly this estate (Swanswick) was swarming with ants commonly called "Tom Raffles, and they kept the cane fields quite clean of rats; but within the last ten years or so, these useful little creatures have almost disappeared."

* Numbers of animals have also been supplied to Cuba, Porto Rico, Barbadoes, and Santa Cruz; while Mr. Espeut himself has undertaken to ship some to Australia and New Zealand for the purpose of putting down the rabbit pest of those countries.

For instance, rats, especially the black and brown species, have always caused considerable loss to coconut plantations by attacking the young nuts on the trees and destroying them, sometimes in mere wantonness, in immense numbers. With the spread of the mungoose, I am informed that more rats than formerly have taken refuge in coconut plantations, apparently driven away from sugar estates by the mungoose; and, as the latter cannot climb, the rats are apparently quite safe. This, I fear, will always be the case, especially with the black rat, which nests in trees, and is a splend d climber. It is only in the open, where cultivation is carefully kept up, and the rats have no special shelter or trees to climb, that the mungoose is a successful rat-killer. Coconut planters are now, however, protecting their trees when grown up by placing strips of tin around the stem, about six feet from the ground, after effectually clearing out the rats and their nests from the trees. Bats, here called "rat bats," probably do quite as much harm in some districts to young coconuts as rats, and to depredations of this kind there would appear to be no remedy.

The cultivation of cocoa will no doubt ultimately benefit by the introduction of the mungoose to a considerable extent. The peasantry have hitherto suffered so severely by the depredations of rats that this cultivation has never been taken up by them on a large scale. Owing to the introduction by Government of the best varieties of cocoa from Trinidad, and the energy displayed by several large planters in establishing plantations, cacao is likely to prove a very important industry in the island.

The following table will show the rapid increase which has taken place in the export of cocoa from Jamaica since 1874:

Year.	Quantity Exported.	Value.
1875	311cwt..	£873
1876	459 ,, ...	1286
1877	375 ,, ...	1051
1878	1694 ,, ...	7832
1879	2153 ,, ...	6631
1880	3304 ,, ...	10,918

Where large areas are planted with cocoa, and where the ground is kept clean and open, the mungoose must prove of great service in checking the depredations of rats, and the trees being small and low rats would be unable to make a permanent lodgment in them.

Similarly with coffee, which has hitherto suffered most severely from their depredations. The proportion of "rat coffee" on some estates is probably one-twentieth of the whole crop, and it would be larger still if it were all carefully gathered and cured. The actual damage done to coffee by rats has been estimated as high as £15,000 per annum, and probably this is not far beyond the mark.

In some districts the greater yield of coffee and cocoa, in recent years, has been attributed more to the influence of the mungoose than to the increased area under cultivation. Certainly the large increase of our exports in cacao during the last five years cannotbeaccounted for alone by the increased area devotedto this culture.

The actual benefits conferred by the mungoose of the cultivation of corn, arrowroot, sweet potato, peas, and those ground provisions cultivated by the negroes, cannot be estimated at present. "Where the cultivation is neglected, and grass allowed to grow plentifully, from my own experience," says a planter, "with the growth of corn the mungoose is of little or no advantage; but when the land is kept clean, and the mungoose has free action to see and dart upon its prey, I am of opinion it is of immense advantage to corn, &c."

Turning now to another phase of the subject, viz., the injuries said to be inflicted by the mungoose on poultry and other domestic animals, the general opinion amongst the negroes and those who have not suffered severely by the depredations of rats is of a character decidedly unfavourable to the mungoose.

It is but natural that an ichneumon should eat eggs and destroy chickens when other supplies fail; but from my own experience (and I have some one hundred and fifty fowls running freely about the yards) I cannot recall a single instance in which eggs or chickens have been actually destroyed by the mungoose, and it is, and has been, for some time, very prevalent in the neighbourhood. Many of my correspondents, however, state the fact, and on this account the negroes destroy the mungoose whenever they find it. The evils as yet, is not of a serious character, whatever it may eventually attain, and certainly not greater in most districts than that formerly caused by rats before the mungoose became common. At present there would appear to be no diminution in the supply, or increase in the price of either poultry or eggs. It is said that the mungoose will not trouble any fowl-house near which a dog is kept, and, as it is a day walker, its depredations in these respects are likely to be kept within comparatively reasonable limits.

From the naturalist's point of view, the acclimatisation of the mungoose is likely to cause a disturbance in the distribution of many of our indigenous animals, which is much to be regretted. For instance, quaill wild guineafowl, and most ground-hatching birds, are rapidly diminishing.

Sea and water fowl are also being attacked in several of their nesting places, with the evident result of their being gradually reduced. The yellow snake, or boa (Chilabothrus inornatus), itself a good rat-catcher, and the "meek-faced" ground lizard (Amevia dorsalis), are also becoming daily more scarce.*

The diminution and probable extinction of animals, in no sense dangerous, but, on the other hand, highly useful, may hereafter considerably alter the conditions of animal life in the island. For present, however, we can only note the facts as they present themselves to us, leaving it to the naturalist of the future to draw his own conclusions.

One view is, that when the mungoose has attained its maximum distribution, and its food supply is diminished, it will, like the Raffle ant and Agua toad, become less felt in the economy of life, and find its natural place with the rat—but both in diminished numbers. While on this subject—the due balance of animal life—I may mention that it is the opinion of one trustworthy correspondent that the Agua toad, when it swarmed over the island, by destroying the predatory insects which held the ticks and grass lice in proper check, brought upon us the present tick infliction of the colony. If this view be correct, then we may hope that, now the toad is diminishing, we have also seen the worst of the tick plague. Truly, a consummation much to be wished!—D. MORRIS, Jamaica, Feb. 24.—*Field.*

LEAFLESS PLANTS.—The anatomical structure of plants bearing phyllodes, or stems with few or no leaves, such as *Ruscus*, *Asparagus*, *Acacia*, *Spartium*, and *Casuarina*, has been examined by H. Pick, who finds that as the amount of foliage decreases so the stems approach in structure to the leaves, the cortical parenchyma assuming the palisade form to common in the upper surface of leaves, while numerous intercellular spaces and stomata are also present. He has also found that plants with few leaves give out most oxygen and assimilate most. When light is excluded starch is stored up in the plants in the course of two or three days, while in plants with abundant foliage this takes place only in from eight to fourteen days.—*Pharmaceutical Journal.*

* As a means of destroying the dreaded Fer-de-lance, or rat-tailed snake of St. Lucia, the mungoose might do good. It would be interesting to learn whether it has been tried, and with what result.

PRELIMINARY NOTICE OF AN ALKALOID IN THE BARK OF FRAXINUS AMERICANA (WHITE ASH).*

BY PROFESSOR FREDERICK B. POWER, PH. D.

In the course of some experiments which were undertaken a few weeks ago by Mr. H. M. Edwards, under my direction, in the chemical laboratory of the Philadelphia College of Pharmacy, our attention was directed to the presence of an alkaloid in the bark under notice. The body in question is apparently quite a strong base, and is, with a considerable degree of probability, the principle upon which the therapeutical virtues of the bark depend; the preparation of the bark which has been most successfully employed for obtaining its specific action being a wine, for which a formula has been given by Mr. Thomas S. Wiegand.

The object of this brief notice at this time is primarily to make known the observation, which is attended with special interest from the fact of no alkaloid having as yet been observed in plants of the natural order of Oleaceæ, and furthermore, as Mr. Edwards, a student of the present class, will not have the opportunity of pursuing the investigation to request that the further chemical investigation, of the subject be reserved for the writer.

The researches herewith connected, embodying the isolation of the alkaloid, its description, composition and properties will be completed and reported upon at the earliest possible date.—*Pharmaceutical Journal.*

INVESTIGATION OF THE ARGENTINE QUEBRACHO DRUGS.†

BY O. HESSE.

Quebracho Colorado.

The red quebracho occurs especially in the northern portion of the Argentine Republic, where, besides being called "quebracho colorado," it is known under the name of "cevil colorado." The plant belongs to the Terebinthaceæ, and Griesebach named it *Loxopterygium Lorentzii*. The name *Quebrachia Lorentzii*, used for it by Arata, would appear to be superfluous.

The bark of this tree, in consequence of the considerable amount of tannin it contains, is used in its native country for tanning purposes; whilst the wood only appears to be used in the preparation of an extract which according to T. Stuckert, is manufactured in Santiago del Estero.

The wood, as its name implies, is of a red colour, due essentially to a substance occurring also as a solid exudation in the cracks and fissures. Pedro N. Arata,‡ who first observed this exudation, named it "gummi quebracho." This gum is of a ruby colour, friable, and yields to ether a neutral crystallizable substance, also soluble in water, which is not coloured with perchloride of iron. The residue, after treatment with ether, is insoluble in chloroform and freely soluble in cold alcohol. The alcohol solution, which is intensely brown-red, separates brown-red flocks upon an admixture with ether, but remains clear when water is added. This solution is neutral and gives with sugar of lead a brown flocculent precipitate, and with perchloride of iron a dirty green precipitate, which becomes violet upon the addition of a little ammonia, or sodium carbonate or bicarbonate. Arata is of opinion that this substance, is a peculiar tannic acid, which he calls "quebrachotannic acid," but the author's observations incline him to look upon it as a catechin-like body.

The therapeutic action of red quebracho wood, first observed by Penzoldt, which is said to resemble that of the bark of the white quebracho, naturally suggested that in this case also the action was probably due to an alkaloid, which was at first thought to be aspidospermine. Although Volhard* failed to detect any aspidospermine in the wood, Lutz† subsequently separated by means of ether, from an "extractum ligni quebracho" purchased from Büdingen, of Frankfort on Maine, a substance that showed clearly the reactions of aspidospermine.

On the other hand Fraude‡ announced that Arata had separated from quebracho colorado an alkaloid that had a composition and properties differing from those of aspidospermine. But this statement depended upon a misunderstanding of the part of Fraude, against which Arata put forward a protest. He wrote to Fraude:—"Le Quebracho colorado ne contient aucun alcaloïde. Je vous supplie de rectifier, dans votre prochaine communication, cette affirmation, qui pourrait faire continuer dans l'erreur plusieurs personnes sur la nature de ces végétaux."

It remained, therefore, only to test Lutz's statement, the correctness of which was the more doubtful in that Volhard had found the red quebracho wood free from aspidospermine, and the author could find no alkaloid at all in it. An examination of the extract, obtained from the same source, as might be expected, gave not the least trace of an alkaloid.

But although the presence of alkaloids in the preparations at present made from quebracho colorado wood has been unanimously negatived, it cannot be denied that the bark of the red quebracho, which in this respect has been apparently overlooked, actually contains two alkaloids, though scarcely in more than traces. These two alkaloids are obtained by the same process as given for the white quebracho. If the ether residue be dissolved in dilute acetic acid the yellow-brown solution gives with potassium sulphocyanide a precipitate of one alkaloid, whilst the other remains almost entirely dissolved and can be precipitated with ammonia.

Together with the flocculent sulphocyanide the greater part of the yellow-brown colouring matter goes down. If the salt be decomposed with soda, the base extracted with ether, and this soultion, after being treated with animal charcoal, shaken with a few drops of very dilute sulphuric acid, the acid acquires a magnificent blue colour, and now gives all the reactions characteristic of the alkaloid. As the acetic acid solution of the original mixture is not blue, but yellow-brown, it must be assumed that the blue-colonring alkaloid is not present originally, but is subsequently formed from another one. The correctness of this opinion may be demonstrated by boiling the acetic acid solution with some perchloric acid, when it at once becomes greenish-blue, and not unfrequently, by longer boiling, blue, like the sulphuric acid solution. It would follow that the blue-colouring alkaloid is an oxidation product.

The second alkaloid of the quebracho colorado bark fortunately exhibits greater stability. By treatment of it in acetic acid solution with animal charcoal and then precipitating with ammonia, it is obtained perfectly pure.

Loxopterygine, as this new alkaloid has been named by the author, is obtained in this way in white amorphous flocks, freely soluble in ether, alcohol, chloroform, benzine and acetone, and but slightly in cold water. It is amorphous, has a strongly basic reaction and tastes intensely bitter. With perchloride of iron it gives no coloration. It dissolves in concentrated nitric

acid with a blood red colour, which soon becomes paler; in pure concentrated sulphuric acid with a yellowish colour, which upon the addition of a little molybdic acid becomes first violet and then blue, and upon the addition of potassium dichromate violet. In perchloric acid it dissolves colourless in the cold; upon warming the solution becomes brown-red. The acetic acid solution of loxopterygine gives with ammonia, caustic soda, and sodium carbonate or bicarbonate a white flocculent precipitate which when dried in the air is anhydrous.

Loxopterygine melts at 81° C. (uncorr.), and quickly decomposes if this temperature be exceeded; eventually an oil distils over that appears to be chinoline. The analysis was made with the ammonia-precipitated substance; unfortunately, from want of material,* it had to be carried out with very small quantities. The results corresponded with the formula $C_{13}H_{17}NO$; but the author has reasons for considering that double this formula—$C_{26}H_{34}N_2O_2$—is more correct. This formula however, is only given with reserve, as the yellow flocculent platinum salt, obtained by precipitating the hydrochloric acid solution of the base with sodium plantinochloride, gave more platinum than is required for a neutral salt, though this might have been due to an admixture of acid salt. The solution of the alkaloid in hydrochloric acid gives with mercuric chloride a white amorphous precipitate, with gold chloride yellow amorphous flocks very difficultly soluble in acids and water, and with phosphotungstic acid an abundant white amorphous precipitate.

Besides these two alkaloids and a tannic acid the red quebracho bark contains nothing noteworthy.

CONCLUDING OBSERVATIONS.

This above described investigation of the drugs coming from the Argentine Republic under the names of quebracho blanco and quebeachod colorado has led to the discovery of several alkaloids, peculiar to each kind of quebracho. Only those, however, are of prominent interest which are contained in the bark of the white quebracho, and which by their reactions and composition give evidence of their relationship to one another. Passing for instance from aspidospermine to the alkaloid met with in the bark of more favourable origin, it may well be imagined that the plant forms from it the other alkaloids in a simple manner, which may be expressed somewhat as follows:—

$C_{22}H_{30}N_2O_2 - H_2$	=	$C_{22}H_{28}N_2O_2$
Aspidospermine.		Aspidospermatine.
$C_{22}H_{28}N_2O_2$	=	$C_{22}H_{28}N_2O_2$
Aspidospermatine.		Aspidosamine.
$C_{22}H_{28}N_2O_2 - CH_3 + H$	=	$C_{21}H_{26}N_2O_2$
Aspidosamine.		Hypoquebrachine.
$C_{21}H_{26}N_2O_2 + O$	=	$C_{21}H_{26}N_2O_3$
Hypoquebrachine.		Quebrachine.

Further, it is not impossible that the plant, in another phase of its development, follows the opposite process in the formation of the alkaloids, starting consequently from quebrachine.

Nearly allied to these alkaloids are paytine and paytamine, which more than ten years previously the author† separated from a bark at that time unknown to him, but since recognized as from a species of *Aspidosperma*. Meanwhile paytamine has been found to originate simply in are arrangement of paytine, and it has, therefore, a similar composition. Both substances give upon boiling with perchloric acid a fuchsine-red solution, like some of the quebracho alkaloids. With the single exception that paytamine does not take a cherry-red colour with perchloride of iron, this alkaloids possesses almost the properties of hypoquebrachine, which it closely approaches also in composition, showing only a difference of H_2O.

Hypoquebrachine	$C_{21}H_{26}N_2O_2$
Paytamine	$C_{21}H_{24}N_2O$.

Notwithstanding this similarity the author has not succeeded in obtaining paytamine from bark of the white quebracho, or in converting hypoquebrachine into paytamine. Also the attempt to separate hypoquebrachine (and aspidospermine) from the white bark from Payta gave a negative result.

It is therefore established that the bark of the white quebracho and the white bark from Payta, each of them derived from a particular species of *Aspidosperma*, do not produce the same alkaloids, but only bases between which there is a resemblance. The possibility, however, is not excluded than in the course of time an *Aspidosperma* bark may be met with that may contain all these alkaloids together. The genus *Aspidosperma* includes forty species, of which at present only two have been examined.

Moreover, the genus *Aspidosperma* stands in close relationship to the genus *Strychnos*, and this explains why the *Aspidosperma* bases at present obtained present in their reactions a certain similarity to the *Strychnos* bases. This similarity appears to extend even to the physiological action, although the *Aspidosperma* bases are less powerful in their action than the *Strychnos* bases, especially curarine.

Although the general results communicated by Penzoldt might incline us to look favourably upon the bases from *Aspidosperma quebracho*, the author is of opinion that the above-mentioned near relationship between the two genera should not be overlooked as imposing a certain degree of caution in the use of the bases in question. Especially he considers it to be indicated that in the treatment of human disease, instead of the *mischmasch* of alkaloids from *Aspidosperma Quebracho* the pure alkaloids should be used. This of course would not exclude the *mischmasch* from being available to the physician; but for the avoidance of confusion he thinks it should not bear the name "aspidospermine," or, as in Buenos Ayres, "quebrachine," but should be called "quebrachetum."*

Finally, in what relation the alkaloids of the red quebracho stand to the *Aspidosperma* bases cannot at present be stated; but that they will now and then be met with in quebrachetum appears probable from the fact, that occasionally this mixture when boiled with perchloric acid will give a bluish or a green solution. Probably in the preparation of such quebrachetum a material has been used consisting more or less of the bark of the red quebracho.—*Pharmaceutical Journal.*

* From 6 kilograms only about 0·5 gram loxopterygine could be obtained.

† *Annalen*, cliv., 287. The name "paytamine" was first chosen for the amorphous alkaloid in 1877 (*Berichte*, ix., 2969).

LIBERIAN COFFEE IN TRINIDAD.

(Extracts from Mr. Prestoe's Botanic Gardens Report.)

LIBERIAN COFFEE (*Coffea Liberica*).—The Liberian coffee trees being the subjects referred to in my notices of this coffee published in 1876 and 1877, it seems desirable to recall here the conditions under which they started and the various features which have presented themselves during development subsequently.

Drawing my conclusions from the appearance of the few plants received in 1875 from Kew, as also some information of the habit of growth as presented by this coffee plant in Liberia, they were planted in a shady position under a notion that shade was necessary if not indispensable, especially for young plants as they were.

They were planted at intervals of 10 feet with Moka coffee plants alternating: the only preparation

* This word is formed after the model of the word "quinctum," which, as is known, describes a *mischmasch* of cinchona alkaloids.

being roughly-dug two-feet holes or pits with a small application of vegetable mould as the plants were put in.

Their growth was most vigorous, some of the leaves being over a foot long and of a rich metallic green colour, but the stems ran up 4-5 feet without throwing side branches, except as "robber" stems, and this character has been perpetuated in almost all the trees; they are thus what is known commonly as "*leggy*" trees.

This of course is not the most desirable habit of growth either in respect of fruitfulness on a given area or for convenience or economy in picking the crop. It is entirely due however, 1° to the too shady position, 2°—to the proximity of the Moka coffee trees interlocated, and which also grew enormously, and 3°—to the plants having been raised in pots and unavoidably crowded together from the first. The same character of growth occurred with the plants first planted in Java, and was there attributed by Dr. Scheffer to the same or similar influences as those cited above. The same leggy character would of course result under similar conditions anywhere, especially if the young plants be allowed to be interfered with by weeds or other growths. Visitors who have seen the Liberian coffee as it is in Liberia however, on seeing two of the specimens first planted here, have remarked, "that is just as they grew in Liberia as a rule; the people don't plant or look after them, and they are there as often in clusters, or mixed up with bush as occurring singly, and generally bearing more at top than at bottom."

That this leggy habit of growth is by no means its strictly natural one, and such as it assumes in positions of full exposure and with room for free expansion, is fully proven by specimens in the gardens, some of which were planted subsequently to 1875 under very slight (moveable) shade at the beginning and then left to full exposure.

Under such treatment the habit is perfectly pyramidal on a height of 5 feet being reached—the extremities of the lower branches touching the ground, although occuring on the stem over one foot above the base.

Fine examples of this habit of growth are to be seen in different parts of the island—specially at the Hon'ble Dr. Mitchell's, Melville Lodge, and the Hon'ble A. P. Marryat's, Marabella.

Besides the fine pyramidal form assumed under full exposure, the form and texture of the leaf is greatly improved, in the sense of advantage to the cultivator. Altogether smaller, more erect, and of sturdier texture, they give the tree an aspect to suggest its perfect adaptability to open field culture. The joints are shorter, the branches sturdier, and the tree is altogether more compact and calculated to yield a far larger crop on a given area, than when grown in shade.

In a "free" hillside soil, or a stiff one either hillside or low flat opened up by proper tillage—conditions which occur in the gardens here—anything like a *general* or *uniform* shade—even when afforded by trees of thinnest foliage—would evidently be a mistake. The plants being put in some time between May and September, a single bit of Palm leaf to prevent the plant from "blistering" at starting is all that is required, and scarcely that in cloudy weather. At the same time a certain amount of tree growth other than that of the coffee and of course mixed with it—either in a scattered form or in regulated belts of unkept tree-growth—will always be necessary, not so much for shade as for maintaining as largely as possible those conditions which are found in "recently cleared land in the forest, and which are so well known to be highly favourable to coffee of all kinds, as well as economic trees generally. Such shade and humus-yielding trees should be judiciously selected and properly prepared for, as one of the elements of vital importance in culture of this coffee on a large scale and for an extended period. In very good or rich low land no shade appears necessary or even desirable.

The distance from plant to plant on flat land should be from 10 to 16 feet according to character of soil, and on which the future size of the coffee tree will depend more largely than on any other influence. On hillsides sometimes the distance might probably be less than 10 feet—the incline giving an increase in "head-room."

As an intercrop and such as will afford a genial and necessary starting shade, plantains might be employed (and profitably) planted in a manner to evenly alternate with the Liberian coffee plants and be allowed to bear one crop. No ratooning should be allowed, but where shade for a second year proves necessary, the plantains should be re-set regularly and singly, as before.

As to permanent shade, or rather renovation trees, they should occur only so as to give a lateral or partial shade of about one-fourth of the area dealt with. Trees of erect habit are to be preferred to those of spreading habit; a good example of the former is the pois doux or *Inga laurina*, a tree admirably adapted for *line* or *belt* planting.

In clearing forest, or land having large tree-growth, the requisite amount of shade or renovation trees should invariably be left in lines, belts or clumps —especially on barren spots or exposed eminences. Indeed, an eminence or ridge should never be bared of original forest-growth, in a tropical country—whatever the cultivation may be.

The manner of raising ordinary coffee seedlings in beds preparatory to planting in the field is pretty generally and well known. The same plan can be followed with the Liberian coffee; observing only that till the seed and seedlings have got their first leaf, more shading and a great deal more water will be required through the dry months—during which, the seeds being gathered at the end of the year, the seedlings must be raised. In fact the very young seedling Liberian coffee is semi-aquatic, and the development of *tap-root* is tremendous. The less this tap-root is interfered with or injured the better—although it can be almost entirely removed, and yet with shade and moisture the young plant quickly re-establishes itself.

Seedlings of Liberian coffee are very liable to the "turn" or "doubling" in the tap-root—properly regarded as objectionable by coffee-planters generally. This appears to arise chiefly from the bulky character of the young tap-root (or radicle), and the strong character of the parchment covering the bean, and by which the growing point of the radicle is conducted round the bean in germination, and thus the "turn" is set up. The remedy to this is the removal of the parchment—though not by drying, or the vitality of the seed will be lost—and laying the beans all flat side downwards, as sown.

Altogether, the Liberian coffee is a beautiful tree. Its stately form, rich foliage, and general vigour being strongly expressive of its superiority above its fellows —at least on the same level. Its pure white, highly fragrant, and thickly-clustered gardenia-like flowers make it one of the most charming objects. but like its fellow the *C. arabica*, its flowers last but 24 hours. Unlike it, however, as to the time of flowering—for it has a full autumn as well as a spring flowering, and at both seasons there is a more or less *successional* flowering—the *extent* of this apparently depending on the amount of fruit with which the tree may be already burdened.

There does not appear to be any uncertainty with the Liberian coffee in respect of the *setting* of the fruit, as exists with the *C. arabica* even at elevations at which it appears to be most perfectly at home. The number of fruits to follow the flowers appearing to depend entirely on the strength of the tree to carry them.

This character tends most largely to assure to the Liberian the palm for productiveness.

Owing to this capacity for fruitfulness at various

seasons, both flowers and berries—and those, too, ripe—are often to be seen on the tree at the same time; as however the chief flowering occurs December to February, the berries are, as a rule, sufficiently ripe—if not fully coloured before the great outburst of flowers and can, as indeed they should at all times, be removed before the opening of new flowers.

The uncertainty of the blossom "setting" fruit in the case of *Coffea arabica* is only too well known, even in Ceylon, at what is regarded as suitable elevation. It is still greater in the West Indies at a necessarily very low level, but at this same level; the Liberian is uniformly fruitful; and hereby as noted from the first, lies its chief usefulness and value. What is now wanted is a hybrid that will possess the character of productiveness at low level combined with the superior substance and flavour of the bean of *Coffea arabica*. The attainment of such a variety would only result from much patience and skill, but it is not too much to hope for.

It is found that on trees more or less shaded the berries take much longer time to ripen, and are much less highly coloured than on trees fully exposed, on which indeed the ripening with high colouring occurs a month or six weeks earlier.

The berries produced on young vigorous trees are often over an inch through lengthwise, but the beans are not so much larger in proportion to those of the *C. arabica*, nor than the beans borne in *smaller* berries either on the same or older trees—on which indeed the berries are invariably of diminished size and at the same time of greater uniformity. I have not found in any case that an increased size of the berry is accompanied with an appreciably larger bean.

I observe that the fruit on the older trees is not only smaller than on younger trees, but the pulp is much thinner and generally of a more satisfactory character to the cultivator; it then agrees very nearly as to size with the "cherry" of the *Coffea arabica*, and proves much more susceptible of drying in the "cherry" state, in the manner I find it is dealt with in Liberia.

The outer or "pulp" part of the Liberian coffee berry is extremely tough and hard, and suggests some difficulty in extracting the beans the refrom.

There is also an objectionable stickiness in the mucilaginous covering of the parchment which greatly interferes with rapid shelling from the fresh pulp.

In the face of this and the fact that the entire fruit can be readily dried into a crackling, it would appear that the method of preparing the Liberian coffee for the market will be in conformity with this, and by means of a modified hulling machine to get out the bean from the crackling or *dried* "cherry."

The berries ripening from November onwards is here a circumstance in favour of this process, (as also the gathering—in the face of an unsteady and expensive labour) for, as a rule, fine weather prevails. A further and remarkable feature in favour of this process is the non-fermentable character of the fresh fruit—its surface being dry—by which amassing for convenience in unsteady weather would be largely practicable.

As to the character of the crackling Coffee in respect of hulling as compared with that of the ordinary Coffee, the difference is not in favour of the Liberian. Dealing with crackling coffee as suggested above and which has been carefully observed, it is found that in a pound of Liberian coffee in this form the weight of the beans is 7½ oz., while the weight of the refuse crackling hull and parchment is 8½ oz.

In a pound of crackling Creole coffee (*Coffea arabica*) the weight of beans is 11 oz., while the weight of refuse crackling hull and parchment is only 5 oz. The waste tissue in Liberian coffee is therefore about 70 per cent more than in Creole of *Coffea arabica*.

The general character of the beans, more especially of those received direct from Liberia, as compared with beans of *Coffea arabica*, and varieties, is coarse, dull in colour, and uneven. The bean is of an ovate shape, with a very wide fissure running diagonally across its flat side.

As to weight of bean a great deal of course depends on the state of dryness, but at the degree it may be assumed to be fairly marketable, 1,000 beans go to the pound, while ordinary *Coffea arabica* beans go 1,300 or 1,400 to the pound, at the some time Liberian coffee beans can be easily dried up to 1,200 to the pound.

In all published accounts which have come under my notice, the Liberian coffee has been represented to be of superior flavour and of much greater yield than *Coffea arabica*—so much so that it had become monopolised by American dealers, but from the earliest notices, nothing has been said, so far as I am aware, as to the general character of the bean as obtained by careful scientific test. In the earlier notices, the tree and its produce were alluded to in general terms only, and not without exaggeration.

Quite recently favourable accounts as to yield have been received from Ceylon, but so far I do not find any particulars of the character of the bean produced there, but the prices quoted for Liberian coffee sold in London would imply that it is regarded as superior.

It would appear that in America it is esteemed by dealers as a good coffee for mixing—*i.e.*, giving body to thin flavoured kinds.

The tests to which it has been subjected here would indicate it to be a 'fair' coffee, and as such I received the testimony of the late Dr. Imray who paid close attention to the subject of its cultivation in Dominica. Beans received direct from Liberia did not however support this character of 'fair' and newly gathered beans produced here were not much better, only they were of a different flavour—being in fact quite green and possessing characters common to green vegetable tissues—by no means agreeable. A sample from the same gathering 12 months old however produced very different results, and justified the term 'fair' as to quality.

The flavour is very distinctive, and specially remarkable in its diffusive and penetrating character, and which I imagine constitutes its superiority in the American market as a "*mixing*" coffee.

Flavour and consistence will of course vary with circumstance of soil, age of bean, as also of the tree producing it. In the tests made here, however, I have found nothing to constitute it a superior coffee to the produce of *Coffea arabica* and varieties. Further, the samples tested were distinctly deficient in the fine piquant aromatic flavour characteristic of Moka, and the fine Trinidad creole coffee—which however is inferior to none the world produces.

Information bearing on the flavour of the Liberian coffee, as well as on the geographical distribution of the L. coffee plant was voluntarily communicated to me by an intelligent old African whose early life was passed in the Mozambique—*East* Africa. He was engaged cleaning a sample of Liberian coffee and proceeded to remark in a pleasant tone to which he was evidently aroused by having to deal with "home" material—"plenty "of this coffee grows in my country, but the people "don't like it too much. Portuguese and French people "come from the ship and take the berries, make the "childern pick them and carry them away, but, my "country-people don't use them if they can get the "other quality" (*Coffea arabica*), and then putting his hand on a tray of nutmegs hard by, he remarked "my country got plenty of these too, but people "don't bother to pick them up, because there are too "many all about." Now as Nutmegs and Cloves are known to be shipped from the Mozambique quarter, it is probable that the old man's information as to Liberian coffee is correct, and the species, (possibly introduced) or one like it is to be found there also.

Coffea zanguebariæ. Lour., without description is mentioned in Hiern's monograph on African Coffees.

Being desirous to ascertain the relative amount of the coffee alkaloid in the Liberian and coffee Arabica (Creole) I have been so fortunate as to obtain, under the sanction of His Excellency the Governor, the assistance of Professor McCarthy, Government Analyst, who has been kind enough to furnish me with the results of his analyses, as follows :—

	Caffeine. per cent.	Fat per ct.	Ash per ct.	Potash per ct.	Phosphoric Acid. per ct.
Liberian coffee...	·77	6·625	4·25	2·13	·436
Coffea Arabica...	1·65	10·375	4·28	1·95	·455

The difference in the respective percentages of alkaloids and fat would point to the inferiority of the Liberian coffee. It is well known, however, that much of the flavour of coffee depends on the aroma which is developed during the preparation and roasting. The excellence of a coffee, as judged of by the popular taste, does not so much depend on the oily matter and alkaloid present as on the quality and quantity of the albuminous and other extractive substances with which the alkaloid and fat occur. Prof. McCarthy has promised to continue his researches on the subject, and later I hope to be able to publish the results of his analyses more in detail.

In estimating the productiveness of the Liberian coffee, or value of its yield on a given area as compared with the same in *coffea arabica*, due regard should be paid to its habit, characteristics of growth, and the way in which it is affected by climate or locality.

Quite recently an account has been given of trees in Ceylon bearing at the rate of 25 cwt. and more per acre.* This, however, is probably based on exceptional cases, and is calculated to mislead. It appears quite possible that a single tree might be met with to bear a quantity (of even dry coffee) at that "rate," allowing so many trees to the acre ; but practically I do not think such a yield likely to occur *per acre*. But as to yield *i.e.*, weight of bean on a given area : judging from what trees in the gardens here have done, as also others in other parts of the island on attaining their fifth year, the Liberian coffee is a surer, and, therefore, a heavier cropper than the "Creole" coffee—at least at the same or nearly the same low level—and, if regard be had to the average yield of this latter coffee *per tree* in Jamaica, French Antilles, Bengal and even Ceylon, there remains a very wide margin in favour of Liberian coffee.

The ordinary yield of coffee per acre in Ceylon is stated to be 4 to 5 cwt., and the figures given as export together with acreage of fruiting trees corroborate this, and which per *tree* is under 5 oz ! The same for Southern India is barely 3 oz : for Jamaica and the French Antilles scarcely so much. A Liberian coffee tree can therefore, according to data already noted, be relieved of half its wonted crop at *setting* and still bear more to the area than what is now a good yield for *coffea arabica*.

The Trinidad trees of Liberian coffee have now borne, as crop, in the fourth year planted, and without much growth of secondary branches, one thousand to 1,200 berries. Estimating at the rate of even 1,200 beans to the pound, this gives a yield of 2 lb. per tree. †

The present spread of the trees averages 8 feet, but this will in two or three years be ten or twelve ; especially if the trees are kept down to 6 feet high. This yield, however may be regarded as a basis for estimating the yield *per acre* at whatever distance the trees may stand apart—the ground being covered. Standing at greater distance (as indeed under ordinarily favourable conditions they must do) their growth and yield will of course be individually and proportionately greater. Thus, trees to the acre at 8 feet apart, 680, and at 2 lb. per tree, give a yield of 13 cwt. This result, however, is liable to reduction of, perhaps, one quarter under a more complete drying of the bean, and it remains to be seen whether so considerable a yield of beans can be *sustained by the tree evenly over a number of years*. I should say probably not, for I observe that a moderate yield—less than the above—has often had the effect on the branches of preventing them growing food for fruit the next year *equal to* that in bearing.

There is a decided tendency to overcrop fruit on all the trees, and this in extensive cultivation will be a point requiring much careful attention ; especially with young trees. As a rule it can be judged of whether the tree is over-cropped early in the autumn, by the amount of branch produced beyond that on which the fruit is borne. By Nov. or Dec. it should be at least equal, for, if less, the trees is obviously overtaxed with its present crop. It is to be noted at the same time, however, that fruit is often produced *twice* on the same wood, after an interval of a season.

A similarly strong disposition to over-crop occurs with the robust variety known here as Hybrid Moca—second only to Liberian for size and vigour and certainty of setting. Two large specimens of these are recovering from a greatly diminished vitality resulting from over-cropping two years successively. The remedy in respect particularly of young trees of Liberian will of course be judicious thinning of the young fruits.

This disposition to over-fruitfulness in the Liberian coffee, and the effect observable after an interval of a season, point to the conclusion that under extensive and prolonged cultivation the trees will not as a rule go on enlarging so indefinitely as for instance the cocoa or other large trees, but reach their limit in ten or twelve years, and then *renovate* gradually by breaking anew from base of principle or primaries, which have become more or less defunct by successive croppings.

The process of pruning will thus be very simple and what is here the easiest kind of prunning to do, as well as being the most suitable in trees of almost every kind, viz.—removing back to the new break all the branches which show markedly diminished vitality, *i. e.*, those which have borne all the fruit they were able to.

Under this course the pyramidal from of the tree will be very completely kept up, and probably such compactness of height as to render the use of ladders, &c., in gathering the crop, unnecessary to any great extent.

I might here instance a special example of fruiting Liberian coffee tree in the gardens. It is really five years planted, and some eight months more from the seed, but it lost a whole year from sickliness at starting, and has since been prevented doing its best by a neighbouring nutmeg tree and other coffee trees. At this time (January) it has 24 primary branches bearing 960 berries; 34 secondary branches bearing 2,040 berries—total 3,000. Taking the beans so high as 1,400 to the pound, this is a yield of over 4 lb. The tree is over 12 feet high, but its spread is not over 8 feet. The height of the tree, however, would make it necessary to allow it a spread (or area) of 10 feet in estimating on its yield the rate *per acre*, and which thus would be over 17 cwt. This tree has some sign of being overcropped, but it is not marked.

A well-defined portion of the Nursery Extension ground is devoted to specimen Liberian Coffee trees planted without manure in a poor stiff soil—except for trenching—and under exposure. They will not be watered artificially and the most that will be done to them as protection against prolonged drought—which is more likely to be harmful than the sun simply—will be to mulch their root surface with such dry grass as might be procured in any part of the island.

* We feel quite certain that the trees were stated to be exceptional.—ED.

† We shewed recently that in Ceylon 1 cwt. from 50 trees planted 7 × 8 would be a moderate average. That yield per 50 trees would be very nearly 2¼ lb. per tree, while exceptional trees have yielded more than double this quantity of clean coffee.—ED.

So far their condition is perfect, as indeed is the case with this coffee in all sizes from the seed-leaf.

Two trees three years old, fully exposed from the beginning, are now 8 feet high, well branched and fully flowering, in the highest state of health. [This careful statement by so high an authority as Mr. Prestoe is surely encouraging.—ED.]

JAMAICA.—In order to encourage and extend the cultivation of valuable economic plants in the island of Jamaica, the Government has announced its willingness to supply allotments from over a hundred thousand plants now ready in the public gardens and plantations at a charge representing only the cost of propagating them. Amongst the plants specified are the Trinidad cacao, Liberian and Mocha coffee, cinnamon, nutmeg, clove, pimento, vanilla, cardamoms, black pepper, cinchona, jalap, tea, cassia, camphor, indiarubber, balsam of tolu and the coconut and sago palms. The railway and coastal steam-boat companies, too, have offered to lend their assistance by conveying the plants free of charge. Cinchona seed will also be supplied at the rate of 5*s.* per ounce for *C. officinalis* (producing the crown bark), and 3*s.* per ounce for *C. succirubra*. An ounce of seed is estimated to be sufficient to produce twenty thousand seedlings, which, if carefully raised, will plant five acres of land.—London *Times*.

CHINESE VARNISH TREE.—In Dr. Bretschneider's notes on some botanical questions connected with the export trade of China, it is remarked that "it is generally accepted by authors writing on Chinese varnish, that it is produced by *Rhus vernicifera*, the Japanese varnish tree." The Chinese varnish tree is found in the provinces of Chê Kiang, Kiangsi and Sze-chuen. According to Bretschneider the figures of the tree in Chinese botanical books do not at all resemble *Rhus vernicifera*. I learn from Mr. H. T. Murton that a Chinaman at Singapore has about forty acres planted with varnish trees. Specimens sent to Kew prove that it is *Aleurites vernicia* (= *A. cordata* and *Elæococca vernicia*). Seeds of this plant had been previously obtained through a correspondent from Sze-chuen, and have been distributed to Ceylon, Demerara, Dominica, Jamaica, Washington (Department of Agriculture), and Zanzibar. Dr. Kirk reports (September 9) from the last-mentioned place that the seeds "are all a foot high, and I am planting them out."—*Journal of Applied Science*.

CHINESE HEMP PALM.—(*Chamærops Fortunei*.)—In the "Journal of Botany" for June, 1879, Dr. Hance states that he is "assured that the fibrous leaf-sheaths" of *Caryota Oehlandra*, Hance, "supply all the coir so extensively used in this part of China for covering trunks, making brooms, mats, and sandals, and for other purposes." He has lately sent to the museum of the Royal Gardens an interesting collection of objects manufactured from this material, and though they are for the most part different to anything we possessed before the material itself is apparently identical with that derived from the fibrous leaf bases of *Chamærops Fortunei*. We are indebted to Mr. Robert Fortune for a rain-cloak and hat (such as are figured in his "Residence among the Chinese," p 145) made from this material. He calls the palm producing it "the hemp palm" (*Chamærops sp.*), a tree of great importance to the Chinese in a commercial point of view, on account of the sheets of fibre which it produces yearly on its stem" (page 189). He describes it as occupying "a prominent place" on the sides of the mountains in Che Kiang. While Mr. Fortune was at Shanghae an earthquake took place. On the following day "groups of Chinese were seen in the gardens, roadsides, and fields engaged in gathering hairs which are said to make their appearance on the surface of the ground after an earthquake takes place. Some of the Chinese did not hesitate to affirm that they belonged to some huge subterraneous animal, whose slightest shake was sufficient to move the world." Many of the fibres of the hemp-palm were shown to Mr. Fortune as the hairs in question. —*Journal of Applied Science*.

HIBISCUS ROSA SNENSIS.—A flower of a superb variety that we have lately examined is so remarkable in its conformation that its peculiarities are worthy of being placed on record. All goes on as correctly as should be the case with a properly conducted Hibiscus till after the corolline whorl is reached; then the flower breaks out into the wildest extravagance, so that it is difficult to reduce the tangled mass of petals to anything like order. In the ordinary course of things there should be within the petals a tube, bearing at its upper part an agglomeration of anthers, and forming the column or tube of stamens so characteristic of well conducted Malvaceæ. Within and at the bottom of this tube of united stamens is, or should be, the ovary whose slender style traverses the tube and breaks up above its edge into five branches, each tipped with a knob-like stigma. In the flower before us we have a very different arrangement. Instead of the staminal tube we have six solid branches or axes clothed with petals of all sizes and shapes, and each bearing at the top a few stamens surrounding the base of a small but perfectly formed ovary, whose styles and stigmas, however, though present, are but small. It would therefore seem as if the main axis of the flower, after throwing off sepals and petals as usual, suddenly branched into five or six divisions, each provided with an irregular number of petals, and terminated by an ovary. It is difficult to suppose any real transformation here; but if such a phenomenon be invoked, then the five or six branches of the flower must be stamens, but stamens must be very mad indeed to bear complete ovaries at their tips, though we are far from denying the possibility of such an occurrence.—*Gardeners' Chronicle*.

THE DAILY SWELLING OF PLANTS.—With delicate means of measurement Herr Kraus has recently proved the existence of a phenomenon in all plant organs, which is connected with their variable water-content, and consists in a periodical swelling and contraction in the 24 hours. Leaves, &c., decrease in thickness from the early morning till the afternoon, when they begin to swell again, attaining a greater size by night than by day (this is well seen in agave, aloe, and the like). Similary with buds, flowers, green cones, fruits, &c., and with stems and branches. Herr Kaiser had before proved such a period in trunks of trees, and Herr Kraus shows that both wood and bark share in it, independently or unitedly. The various experiments of Herr Kraus—removal of foliage, watering, shutting out light, &c., lead to explanation of the phenomena by the varying reciprocal action of those factors which bring water into the plant and those which carry it away. By night only the water-absorbing activity of the parts below ground operates, by day the water-consuming activity of the parts above ground besides. The water-consuming activity depends mainly on the foliage and on light (removal of leaves or of light stops the contraction) and consists essentially in transpiration. Herr Kraus states that when a plant is watered these things occur:—In a short time, less than an hour, the stem begins to swell; both wood and bark take part in this, the wood always first. The swelling progresses at a pretty quick rate, upwards of several metres per second. After some time, perhaps an hour, contraction gradually recurs. The contraction began at the upper part of an acacia after 10 minutes, whereas the swelling at the lower part continued 50 minutes. This shows that the contract on is due to the activity of the foliage, and is gradually extended downwards.—*London Times*.

NEW FIELD FOR AGRICULTURAL ENTERPRISE; THE NORTHERN DISTRICTS OF CEYLON AND "NEW PRODUCTS": FARMING, PLANTING AND HUNTING COMBINED.

European colonists having turned their attention to paddy (rice) cultivation and their attempts at Tissamaharama in the Hambantota district having met with an encouraging degree of success, there is some reason why public attention should be directed to other districts presenting ample scope for the agricultural capitalist and pioneer. In the Wanni division of the Northern Province for instance there are a large number of abandoned tanks with good irrigable lands lying below them which could be bought outright from Government at the upset price of R10 an acre and fees (say £1 sterling in all), or for responsible pioneers ready to invest, probably even easier terms on a deferred scale of payment could be got. A group of tanks near each other and situated in close proximity to a main road might easily be selected as the site of a farm, to which could be added any extent of fine land suited to the cultivation of new products. The tanks in question are easily repaired, nothing being required but the filling in of the breaches in the banks and the supplying of wooden or masonry sluices. In respect of the latter, probably Government would supply any iron or carpenter work required from the Colombo Factory, free of expense. We are glad to learn that a demand for such abandoned tanks and the adjacent land is now springing up among natives, and some applications have already been sent in to Government for surveys with a view to purchase. As regards means of communication the fine central road running through the province places Jaffna and Matale within easy access of every part of the district we refer to, and there are also numerous minor roads branching off from the main thoroughfare into the adjoining country all of which are available for cart traffic. Sir Wm. Gregory spent his surplus revenue—derived from the coffee planting enterprise in the height of its prosperity—very freely for the construction and improvement of roads in the north and east, and it would be very satisfactory if European as well as native agriculturists now demonstrated the benefit of this investment of public money.

The introduction of "new products" in the Wanni is being attempted by the Government, and an "Experimental Farm" is to be started next year under the direction of Mr. C. A. Murray, one of the most popular Assistant Government Agents in the service. The few plants now growing in the Assistant Government Agent's private garden at Vavuniyavilankulam look well. Two rubber plants show a vigorous life by their fast growth and sturdy appearance, and four Brazilian wax palm plants are about nine inches above ground and look robust. The latter took about five months to germinate, but under the system adopted at Hultsdorf Mills this delay can be overcome in future experiments The climate and soil of the Wanni however are more especially adapted for the growth of cotton and tobacco, the latter product being grown extensively in nearly every village in the district. New varieties are being introduced, and if the crops are properly cured Wanni tobacco think find a ready sale in Europe. The district ought to be equally suited for rubber cultivation on a large scale, and the chocolate (cacao) plant should do well if once started by the aid of irrigation. As regards health, from what we learn we do not think there is much to fear from the climate for European colonists who are ordinarily careful of themselves. The fever which generally appears among the people at the change of the monsoons is of an ordinary type, yielding readily to treatment, and it does not spread to any great extent. Finally we may mention that throughout the Wanni game of every kind abounds, so that lovers of sport can combine agriculture with the pleasures of the chase.

Vavuniyavilankulam is within 95 miles of the railway terminus at Matale, there being resthouses at Nalanda (14 miles from Matale), Dambula (29 miles), Kekirawa (43 miles), Tiripane (57 miles), Anuradhapura (71 miles), and the Jaffna mail-cart makes the journey from Matale to Vavuniyavilankulam in about 26 hours. As the North road is certain to attract planting attention erelong, we may as well put on record the authentic information respecting the mail-cart and journey with which we have been favoured:—"Mails are carried from Matale to Jaffna by cart. Bullocks are used for the greater portion of the way between Matale and Elephant Pass, from whence there is a coach into Jaffna. There are a few horse and pony stages on the road between Tiripane and Vavuniyavilankulam. The bullock cart leaves Matale at 1 p. m., and reaches Anuradhapura at 6 next morning, Vavuniyavilankulam between 2 and 4 p. m. The distance from Matale to Vavuniyavilankulam is roughly speaking ninety-five miles. The accommodation is better suited to a smal than a large man, for the seats are narrow; but I travelled in the bullock-cart from Dambulla to Matale on one occasion, and was quite satisfied. Just now a person may drive his gig or dogcart from Matale to Jaffna perfectly—the road will be in perfect order the whole way. During the N. E. monsoon rains portions of it are like paddy fields. The coach reaches Jaffna at 11 in the morning of the second day. It leaves Jaffna at 2 p. m. and reaches Vavuniyavilankulam at 11 next morning, Anuradhapura at 6 p. m. and Matale at noon next day."

We are promised a full account of the experiment under European auspices at Tissamaharama: who will be the first to pioneer as Farmer, Planter and Sportsman (combined) in the Wanni district of the North?

NORTH BORNEO.

An announcement appeared amongst the shipping arrivals of last week which claims a little more than the mere passing interest usually given to that portion of a newspaper. It recorded the entry into this harbour of the British ship "Archos" from Kudat, and consequently the first opening of trade which, it can scarcely be too much to predict, will before long constitute an important feature in the commerce of the East. British enterprize needs but a reasonable opening to effect startling results; and, in this case, with a country comprizing an area equal to that of Ceylon, and only waiting cultivation and development of its many latent resources to render it a mine of marketable produce of all kinds, it cannot be said but that the opening afforded is one from which most promising results may be looked for, and that at no distant date. Few, if any of those now residing in this island, and forming part of a community actively engaged in business, possessing palatial dwellings to live in, and enjoying institutions and advantages of every kind, realize the fact that, in 1841, or say only forty years ago, the site of this large and busy town was a bare rock, as free of huts (not to say houses) and trees as the top of Kelle t's Hill or the Peak now is. Yet what a hive of busy population and centre of vast trade it has since become! The same may be said of the Model Settlement of Shanghai. That port was opened to trade on the 9th November 1843, when the present British, American, and

French Concessions were simple rice swamps, with clumps of cottages here and there in which the native cultivators thereof lived. Yet now Shanghai claims place as one of the finest cities of the East, and is a nucleus of a trade valued at forty millions sterling per annum. Of course it is not pretended to compare the "New Ceylon" with either Hongkong or Shanghai, or to foretell for it a progress as rapid and gigantic as that accomplished by the latter, for it lacks one important element of success, which has done much to float the last-named places on to fortune, and that is the advantage of position; in the one case upon the borders of a thickly populated empire, and in the other, upon an old established trade route. But what we wish to maintain is that the day of small things need never be despised, and we sincerely trust that the arrival of the "Archos" may indeed be remarkable as the presage of a future of solid success for North Borneo, and of wealth tor those who give their money and their time towards building it into a new state.

As far as we are at present informed, Kudat and Sandakan are the only two places which claim the dignity of settlements and trading ports. The first is prettily situated on a land-locked cove, which juts into the western side of the bay of Marudu, a large arm of the sea, situated in the northernmost point of Borneo Island. The metropolis of the new State is to be established here, and Governor Treacher is only awaiting the erection of his house and offices to remove thither from Labuan with all his subordinates. The settlement consists of a number of Chinese shops and Malay huts, which are daily being added to by newcomers from the neighbouring islands and Singapore. A substantial pier has been erected by a Singapore firm, at which vessels of considerable draught may haul alongside. Having been only started as a station in the month of December last, there is of course little to be said as to the trade of Kudat or of its prospects of trade, but, considering its short life it may really be pronounced to be a thriving place. Sandakan, which is situated in a fine bay that forms the embouchure of the two longest rivers on the east coast of North Borneo, was founded upon a settlement which had originally been a place of considerable native trade, and has therefore made material progress already. It contains a population of 3,000 souls of whom a large and influential number are Chinese. Malays are continually coming in from Sulu and the neighbouring islands, as well as from the distant interior, attracted by the protection and freedom from molestation which they secure under the new *régime*. The trade is yet limited, but it suffices to occupy two steamers, belonging to different parties, and which make fortnightly trips between Sandakan and Singapore, calling at Kudat and Labuan *en route*. The country round is covered with forest, but the soil is rich, and pronounced to be well suited to the cultivation of both low and high country products. Much more might be added as to other portions of the new territory which are likely sooner or later to be brought into prominence. when once labour and capital can be brought to bear. But our object being merely to call attention to the interesting fact that communication has been opened between this colony and Borneo, we will leave these places and their capabilities for further notice hereafter. One thing we are glad to learn on the authority of those who are competent to form an opinion. It is that the Malay population have not only given up their predatory and head-hunting propensities, but are willingly submitting themselves in all directions to the jurisdiction of the Residents, whose grasp of authority is effective in the maintenance of good order and discipline. Even some of the chiefs who were at first recalcitrant, and hesitated to acknowledge the sovereignty of the Company, are now giving in their adhesion with that of their people.—Hongkong *Daily Press*.

PLANTING PROSPECTS IN CEYLON.

NAWALAPITIYA, July 21st.

By the time the train had reached Peradeniya the rain had passed away, and the mountains around and beyond Nawalapitiya stood out pretty clearly, but there is heavy rain again up here. Its result, and no doubt the depression of the coffee industry, is that the natives are cultivating rice more largely than in former years. Note that to leave old coffee as shade for cocoa is right, as you want tree formation. In the case of Liberian coffee it is wrong, because your object should be to get bushes with primaries near the root. Udapolla gave double the estimate of Liberian coffee, and Liberia yielded 1,800 bushels of Liberian coffee. The cocoa trees on Moragalla continue flourishing, while sapan plants are shewing well. A late visitor from Brazil was much struck with the energetic efforts of the planters to retrieve the failure of Arabian coffee by new products. Brazil has plenty of fine soil, but the labour collapse, though postponed for perhaps ten years, is yet inevitable. There are already a considerable number of runaway slaves in the backwoods, and there are constant accessions. Immigration from Europe and China is equally a failure. Coffee has been overdone. The future of Ceylon presents a far more favourable view as regards labour, communications, and a variety of products.

THE UTILIZATION OF PLANTAIN FIBRE.

In copying an interesting article from the Calcutta *Englishman*, we feel bound to say that previous reading led us to doubt whether the fibre of cultivated plantain stems could be profitably utilized for cordage fibre. In the case of these stems, as well as that of the wild plantain, the main difficulty always has been about the cost of carriage of bulky stems to the machine, or of a bulky machine to where the stems were in plenty. Then comes the difficulty of preparation so as neither to weaken nor discolour the fibre. Finally comes the question of the low price per ton offered by London buyers. The "Manila hemp" apart, we have always felt that if plantain stems were ever to be profitably used it must be as half stock for the paper makers. There can be no question, however, that great advances have been made lately in fibre-separating machines, and in the cleaning, drying and preparation of fibres; and the ubiquitous plantain, cultivated and wild, as well as aloes, may in Ceylon be turned to profitable account. The statements of our Calcutta contemporary speak for themselves, and we are especially struck by what he says about the leaves of the pineapple. We have always felt that the long leaves of the plants, as grown in shaded places in Ceylon, ought to yield fibre of value superior even to the fruits, although these will now be in special request for steamers resorting to Colombo harbour. The fibre of the pineapple is strong as well as fine, but, for cordage, we always understood the defect of fibre from stems of the cultivated plantain, was their weakness. This objection will not tell so much, if the material is used for paper making. In these hard times, when coffee planters out of employment are ready to turn their hands to anything, the preparation of fibres from the numerous plants which yield them would seem to offer a field of desirable enterprize, and we feel sure that, if the pursuit is taken up in earnest, Messrs. John Walker & Co. and other engineers will do their part in providing the requisite machinery: simple, strong and light. The

writer in the *Englishman* refers to the leaves of the plantain trees as well as the stems, as fibre-yielders. There is certainly plenty of green material, but the proportion of water is enormous, as any one who cuts a large stem or leaf can see. This large proportion of water has been the great difficulty in former experiments, and perhaps the difficulty could be obviated by the use of a small machine to express the moisture from the stems and leaves before they are carried to the separating machine. Indeed the *Englishman* states that for half stuff for paper it is only necessary to split and cut the stems into lengths and pass them through rollers. If, as is asserted, the Bombay experiment, regarding which detailed figures are given, was so satisfactory and profitable as is alleged, the question naturally arises why was it abandoned, as it appears to have been? We suspect it is a mistake to say that plantains will grow on the poorest soil. Unless manured they exhaust even good soil. Still, if the experiment succeeded in Bombay, it certainly ought to succeed in Ceylon, and we trust it will be fully tried.

In this connection we may notice the suggestion made by a correspondent of a contemporary that paper pulp, the raw form of *papier mâché*, should be used as a covering for scraped cinchona trees. The idea is worthy of attention. It is given in the following form:—

I would utilize paper but in a modified form. In every town there is an enormous wastage of paper cuttings and soiled paper of all sizes and kinds, burnt or destroyed daily, all of which might be turned to account for cinchona covering. Nothing is simpler or easier than reducing cuttings of paper to a state of pulp by the addition of water. Paper soaked and then squeezed or mashed up by hand or any other means, takes the form of a pulp, the foundation in fact of papier mâchè, and in that state could easily be placed in a thin coating round the trees: it would at once adhere the only proviso being that it should not be applied during heavy rain, but once dried on it will be found capable of resisting all but the heaviest rain, and if it remains on the stem for one month its purpose will have been served. The supply of paper cuttings and pieces must be very large in Colombo and Kandy.

Dried leaves of plantain trees ought to be useful as a covering, but they would be bulky to carry and in seasons of drought would be apt to take fire. The paper pulp could probably be pressed free of moisture at Colombo and again moistened on the estate before being applied? If pressed into thin sheets, we fear it would not be sufficiently pliable for use.

(From the Calcutta "Englishman.")

Few persons can long reside in any part of India without being struck by the number of plants, such as aloes, plantains, pineapples, &c., which form a characteristic feature in every landscape.

The stranger from northern latitudes, should he happen to be of an observant and enquiring turn of mind, will reflect on the value of these plants and the various uses to which they could be applied, and he will soon see that they are productive sources of the most valuable fibres of every degree fo strength and fineness, and suitable for working into the most delicate fabrics, as well as for cordage and cables of the greatest strength. The couch upon which he reclines is covered with cloth made from a'ma'echal as fine as silk, and he will be astonished to learn rithat it has been obtained from the leaves of the wild pinecapple, which occasionally forms tho hedgerows of enclosures and is thickly scattered throughout the jungle. He will notice the native craft rigged with superior cordage, and will be informed that it has been twisted from the leaves of the aloe, patches of which from their fleshy leaves he has seen growing around in every direction. Or he will choose from the box of an ordinary pedlar, should he desire to send home a *souvenir* of his wanderings, a scarf of texture almost as fine as that which the spider weaves, made from the leaves of the common pineapple and known in India as *pina*. On seeing a fallen plantain tree of the ordinary kind, he will notice the end of strong white fibres protruding from the broken part, and will be struck by their resemblance to hemp or flax, but on closer examination he will find them to be very similar to the celebrated Manilla hemp, the increasing demand for which in Europe and America he will probably have heard of. And to any one at all informed as to the growing and insatiable wants of the manufacturer, it is a matter of no small surprize that the well-known and acknowledged deficiency in the supply of fibrous materials has not been made up from the numerous sources which in India one sees flourishing everywhere around him. Why is it that countless thousands of plantain trees in India, which are cut down after having yielded their fruit, are allowed to rot where they fall, instead of being utilized for the excellent fibres with which they abound; and why are the numerous species of aloe and wild pineapple plants which flourish on uncultivated and otherwise barren land, and invade every abandoned piece of ground, suffered to send out their fibre-stocked leaves only to flourish and decay; while the demand for fibrous materials in all parts of the world increases every day?

The plantain in India is considered as valuable on account of its fruit alone, but both the stems and leaves abound in fibre useful for textile and cordage purpose, while the tow which is separated in preparing the fibres forms an excellent material for the finest or the toughest paper. Nor is the process involved in extracting the fibres in any way laborious or expensive. Early in the year 1880 the attention of two gentlemen in Bombay was directed to the fibre-producing capabilities of the common plantain suitable for paper making, and after making several satisfactory experiments with machinery of their own invention, they commenced operations on a moderate scale at Bassein, distant about 30 miles from Bombay, giving employment to about 40 day labourers for a period of above one year. The result of these works was all that could be desired, the outturn of fibre, waste, and paper stuff produced at the rate of two tons per diem by the simplest conceivable machinery and at comparatively trifling cost, readily commanding the following prices, on 9th December 1880, in the Liverpool markets:—

Plantain fibre	£20	per ton.
„ waste	£10	„ „
„ tow	£10	„ „

From 800 trees, which was the average daily quantity manipulated by by Messrs. Price & Lacey, the yield was as follows:—

Clean fibre	1 ton
Waste	½ „
Tow	½ „

while the cost of production was as given below:—

	R.	A.	P.
800 stems at R2	16	0	0
Cartage for above	16	0	0
40 coolies, for cutting, splitting, washing, drying, packing, &c., ...	10	0	0
Fuel for engine	5	0	0
Sundries	5	0	0
Total Rs...	52	0	0

To which may be added cost of carriage by boat from

Bassein to Bombay, and freight from thence to Liverpool, which, however heavy freight may have been at that time, left them a large margin for profit. These figures, however, would hardly give a satisfactory idea as to the commercial merits of an enterprize in this direction, as the capitalist would undoubtedly reap greater benefits from an undertaking of this nature were he to obtain his supply of raw material from a plantation of his own. The culture of the plantain is extremely simple, as it will flourish in almost any soil where the climate is warm and moist. It will grow in the poorest soil, and its cultnre might be extended with very little trouble and expense. A young shoot being planted attains maturity in eight months, producing a bunch of fruit weighing 30, 50 and even 100 lbs., and throwing out from its roots and around its stem from 7 to 10 fresh shoots. These will, of course, each become a distinct plant, producing its own bunch of fruit. According to the distances, there may be from 300 to 400 plants in an acre, each producing on an average seven suckers, thus making in all from 2,100 to 3,200 plants in an acre. The produce of fruit at the lowest estimation would be from 900 to 1,200 lb, annually; and this fruit has its market value. But should the supply be in excess of the consumption in any particular part of the country, it could be dried and preserved by a very simple process, in which state it is at all times marketable. Thus it is apparent that the planter who would cultivate the plaintain in large quantites on account of its fibres or the preparation of papermaking stuff would be amply repaid for the cost of cultivation by the proceeds of the fruit yield alone, while the fibre from the stems and leaf stalks for textile and cordage purposes may be extracted at so small a cost, with the aid of simple rollers for crushing the cellular tissues and pressing out the sap and then of an ordinary scutcher removing the remaining extraneous matter, that there is every reason to believe that the planter would find it a very profitable business. For preparing half-stuff for paper makers, we understand that it is only necessary to split the stems, cut them into lengthe of three feet, and pass them through rollers grooved in such a manner as to make them into fine strips, after which they may be dried and packed into bales for export.

The fact of ground rent being in many parts so extremely low, the ease with which a plantation may be raised, and the very small amount of labour required in tending the plants and extracting the fibre or preparing paperstuff, should be sufficient inducement to many capitalists to launch out on a new enterprise, or at least to make the experiment of developing an almost new and certainly sadly neglected industry.

CEYLON FIELDS FOR PLANTING ENTERPRISE: —NEW AND OLD PRODUCTS: TISSA, GOOD; VAVUNIYAVILANKULAM, BETTER; KANTHALAI, BEST.

(*By one who knows all three.*)

"Kanthalai" writes:—"I have read with much interest the article in your paper of yesterday's date headed 'New Fields for Agricultural Enterprise.'

"The 10,000 acres of land surveyed in convenient lots of from 500 to 1,000 acres lotted off for that defunct Jaffna and Batticaloa Company comprize *all* the advantages you desiderate, with the additional one of being irrigable by the Kanthalai tank, and of being supplied by a good road to Trincomalee on one side from which it is distant 25 miles, and from Matale railway on the other (75 miles).

"The soil is as good, if not better, than that at Tissamaharama, and there is the additional advantage of from 3,000 to 5,000 acres of beautiful pasture land round the tank. The climate is *better* than that of Tissa, though I have no doubt *that* is becoming *better* every year.

"The Government cannot surely intend to keep this and locked up any longer, for the benefit of the defunct Jaffna and Batticaloa Company! One wonders now it has been reserved for so long as nearly five years. If thrown open to public competition, on what are known as pioneer rates (R10 per acre paid in four instalments), I have no doubt that much of it would be taken up.

"I send my card, and I am ready to supply any information, that may be required by any intending settlers in respect of this land."

COFFEE IN BRAZIL AND CEYLON.

A proprietor of Ceylon coffee property now at home, but about to return to the island, sends us the following cutting:—

COFFEE FROM BRAZIL.

June 14th, 1882.—Speaking of the exhibition of coffee from Brazil at the Crystal Palace, London, the *Brazil and River Plate Mail* says:—It will doubtless be a surprise to many to learn that the total amount of coffee grown in Brazil during the year 1881 amounted to about 5,000,000 bags of 132 lb. each, being equivalent to one-half the whole estimated production of the world. Of this prodigious quantity, in the same period, 2,241,976 bags were exported to America and 2,135,442 bags to Europe, England receiving 266,756 cwt of the latter and yet to the vast majority of people Brazilian coffee is quite unknown. From its superior and delicious flavour it, indeed, enters into consumption as a componeot part of many of those execrable mixtures which have done so much to discredit and limit amongst us the nse of the aromatic berry, but is seldom if ever sold in our grocers' shops in its own name and in its native purity. The Central Association of Agriculture and of Commerce of Rio de Janeiro, under the auspices of of the Imperial Government, have resolved to put an end to this unsatisfactory and anomalous state of things by opening exhibitions in the principal cities of Europe and by otherwise popularizing the Brazilian product by the diffusion of statistical and authoritative data with respect thereto.

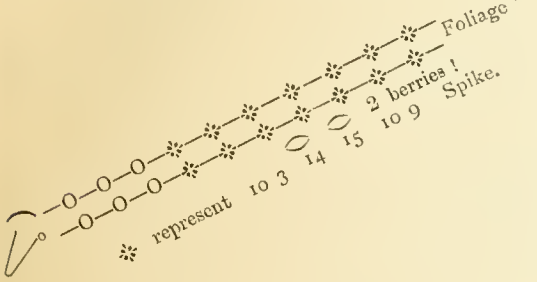
Our correspondent, commenting on the above and on the position of the coffee interest in Ceylon, writes as follows:—

"I send you a cutting out of yesterday's paper on Brazilian coffee: would that our Government would do something in the same direction, though I am not one who believes that the chief industry of Ceylon cannot recover; friends in Brazil advise me that present prices are ruining many there, and have caused a check to cultivation, which must make itself apparent before long, besides which at the present rate of immigration, America will soon double her consumption of the bean. No doubt, times are very hard and we must all husband our resources—saving every penny, not in the too absurd way of starving the goose that lays the golden egg, and spending far and away too much on the style of living, but by giving up some of the absurd extravagancies we fell into during the palmy days of 1876-77; and in my opinion, we shall yet see much brighter days for coffee. No doubt, immense stocks are now held everywhere, but all this is every day losing colour and becoming more and more valuless, as buyers now will only take colory kinds. So the large stock of inferior colourless stuff will do its duty in the shape of mixing into compounds (French coffee, &c.). Immense quantities of chicory are now grown in Great Britain itself. So here at home we have a ready means of adulteration, which legislation should affect. As you may be interested in the leader in the *Times* on crop prospects here I send it you."

FAILURE OF COFFEE BLOSSOM.

Mr. Wall, under date 18th July, writes to us :—"Experience is now rapidly accumulating in regard to all our new enterprizes, and your excellent record of progress in this serial (the *Tropical Agriculturist*) is of the utmost value and interest. I am ashamed that I have individually contributed so little in the way of correspondence, but I am not therefore idle, and I hope my work may not be altogether fruitless. My long absence from home interferes with literary work.

"It is very discouraging, and utterly unaccountable, to find so much abortive blossom on coffee trees of luxuriant growth, and scarcely affected by leaf-disease, or by any other apparent malady, as is to be seen all over the coffee districts this year! Here is a sketch of a branch plucked off a splendid tree full of healthy foliage in one of our very best districts.



"I plucked it whilst asking the manager what had become of the splendid blossom we had seen on that particular spot on my last visit. His reply was, as he looked at the straggling fruit on the tree, 'That is all I can show for the blossom you saw, and one or two other blossoms besides.' We have evidently much yet to learn regarding the conditions necessary to fertility in fruit trees. Our home experiences prove that trees of luxuriant growth and apparently perfect health become absolutely barren at times, and have to be forced, by various expedients, into fruit-bearing. What can we do to our coffee? Manure, our great ally, pruning,—and every other ordinary form of attention have all proved ineffectual this year, and indeed for several years, and we find coffee trees of every variety of age and condition, all involved in one common case, the few exceptions to which are as unaccountable as the rule itself! Having closely and diligently studied several of the remarkable exceptions of fruitfulness in the very midst of surrounding barrenness, I can detect no clue to the marvellous disrepancy! Roots, bark, foliage, soil, each and all refuse to render any evidence. It is God that gives the increase, and it is clear we have yet to learn some of the essential laws and conditions of His work!"

THE LEBONG TEA COMPANY, LIMITED.

Capital £100,000, in 10,000 shares of £10 each, of which 8,207 have been issued. Directors—Sir James Caird, Sir G. U. Yule. Messrs. C. E. Goodhart and D. R. Smith. Area of cultivation, 951 acres. Manager in India—Mr. G. W. Christison. Secretary—Mr. S. Ward. The report and accounts of this concern to be presented to the shareholders at the twentieth ordinary general meeting, convened for today at the Company's offices, have been issued. The revenue account for the year shows the receipts to be £21,359 8s; less total expenditure, £13,798 3s 6d; net profit, £7,561 4s 6d. Out of this £2,462 2s was paid in December last as a dividend of 3 per cent.; £1,348 11s 5d has been placed to reserve fund. It is proposed to devote £3,282 16s to payment of a dividend of 4 per cent., making 7 per cent. for the year, leaving the sum of £467 15s 1d to be carried forward. The profit made by last season's operations was thus more than sufficient to have given the shareholders a dividend of 9 per cent. on the capital. The cost of the crop of last season laid down in London, including all home charges, was 1s 0½d per lb., and the average price realized for the teas was 1s 6d per lb. The yield per acre from the area of plant three years and upwards of age, viz., 729 acres was 313 lbs. The estimated out-turn for this season is 2,900 mds., or 232,000 lbs., *i.e.*, at the rate of 278 lbs. of tea from 833 acres of plant three years old and upwards. The general manager's full and careful report on the state of the plantations is annexed to the director's statement. The report states that the new garden at Barnesbeg has continued to make satisfactory progress, the produce of last year being 215 mds., and the teas from this estate have been much approved by the trade. The extensions on this and the other gardens of the Company may now be considered nearly complete. The estimated yield from Barnesbeg this season is 350 mds., the area of tea three years of age and upwards being 135 acres, which seems to be a very full yield from plant, the larger portion of which is but three years old. The red spider is said to have spread its ravages to parts hitherto free from it, and as this subject is of general interest, we quote the remarks of the general manager in full :—"This pest is set in later, and checked the flushes less in May and June, but more about the middle and towards the close of the season than in 1879 and 1880. It was more diffused and less severe upon the whole than last year. No parts suffered quite so much as the parts worst affected during the previous two years, though *it spread a little more on the places almost free formerly.* Many spiders remained alive on the plants at the close of the season, and the winter was too mild to greatly check them. *At present the pest is worse on the parts comparatively free hitherto,* but taken on the gardens all round it is decidedly less severe than at same date last year. The fields that suffered most were pruned late this season, and as yet the red spider show much less upon them than in former years to same date. But it is too early to offer any decided opinion in the mysterious matter. The improvement may be more apparent than real. The pest may merely be coming on later, owing to the late pruning and coldness of spring. It has been spreading at Badamtam during the latter half, and at Tukvar during the last week of April, and it is certain to be very much worse still by the end of this month. It is but safe, therefore, to reckon that the pest will become fully as general as ever it has been, and that the gardens may suffer as much as last year. And yet we may at least venture to hope that, owing to its commencing rather late, the bushes during the rains will be better able to resist and grow out of it. The spider was pretty general at Barnesbeg, and many of the bushes of all ages there were very red with it last season. Still the garden did not seem to suffer to any extent, and it passed off after a couple of months. At present this division is about as much affected as at same time last year. The sulphur had a beneficial effect last season. One-third of this year's supply has been applied on Mumtick (No. 24) in March, and the remainder will be put on at Badamtam and Vah this month when the spider is reaching its fullest development, and should at that stage do most good, if not

* In which O represent eyes of last crop.
❊ ,, stalks of failed blossoms.
⌒ ,, the two formed berries.

washed off the bushes by rain too soon. It will be seen that it is difficult—if not practically impossible—to apply any remedy effectually over so wide an area, and as formerly stated there can be no doubt but the best safeguard is continued light cropping accompanied by careful cultivation. As noticed in last report, the number of pests that prey upon the tea plant seem to increase rather than diminish in this district, but so far the red spider is the only one that materially affects the Company's interests." The Company's manager surveyed and reported on various properties which were for sale in the autumn of last year, and the directors authorized certain purchases on what they considered equitable terms, but as much inflation in prices occurred just at this period, no purchese was effected; but the general manager is authorized to examine any tea estates that may come into the market, and which may be eligible in quality and position.—*H. and C. Mail.*

NEW FIELDS OF ENTERPRISE:—"MADAGASCAR."

THE TANALA COUNTRY.—This is nearly all a great forest, with few villages of any importance, the great bulk of the people being settled on the low country to the east of it. The eastern edge of the table-land has very steep sides, with many bold and rugged mountains, and waterfalls of great beauty; the country is well-watered and exceedingly fertile, sugar-cane and rice growing in luxriance, with coffee on the hill-sides. Except the dwellers in the five towns, the population is migratory, shifting their quarters as they move to fresh rice grounds. From the Faraona southward, the country is virtually independent, and is under the rule of Zafirambo chiefs, whose head successfully resisted the Hovas in his mountain stronghold of Ikongo. This has a town and many rice-fields on its large flat top; no stranger is allowed to ascend it, and the only access is by long ladders of creepers let down by the garrison. The dwellers in the forest are woodcutters and ironworkers, much iron ore being found at its western edge. The Tanala is the richest district in Madagascar, and presents a fine field for European enterprise in the cultivation of coffee, sugar-cane, vanilla, and even tea.—*Colonies and India.*

NEW AND OLD PRODUCTS IN CEYLON.

(By the Senior Editor.)

Lindula, July 22nd.

While expressing admiration yesterday of "Liberia" and the other clearings a little beyond Polgahawela, I said to a fellow passenger interested in Liberian coffee and cocoa: "There must be large tracts of land suitable for culture between Polaghawela and Rambukkana." His reply was that after six months' search through blocks aggregating over 2,000 acres surveyed by orders of Government with reference to sale he had at length fixed on a lot which was duly advertized for sale. But a forester sent to report on it indicated that the land bore a quantity of useful timber and was within easy distance of the railway. The sale was, therefore, stopped, and the land, it is expected, will either be reserved as Government forest or sold at an enhanced upset price. In either case there will be not encouragement but discouragement to enterprize in "new products." Of course it is very important that Government as representing the public should retain possession of a sufficiency of forest reserves to supply public demand for timber, but Government must take care that the interests of the enterprize on which the colony depends for relief from present depression, are not sacrificed to the one interest of forestry. The natural desire of the professional forester will be to get every tract of land which carries good forest reserved, and the high officers of Government will have to perform the duty of holding the balance true, so that while a sufficiency of forest is reserved, enterprize is not discouraged or repressed.

In this connection a Dimbula planter who was a fellow-passenger held that Government should deal more liberally in the case of reserves alongside streams. Let the planter clear and then plant good trees, said he, but let him have property in the timber, on condition that for every tree he cuts down he shall plant at least one. A large number of planters would thus become timber producers, to the benefit of the colony and Government. The more timber grown, the cheaper would be the cost in the market. This gentleman believes that growing trees for timber purposes will pay, and I feel inclined to agree with him.

The Liberian coffee and cocoa planter stated that while the short squalls of the monsoon of 1881 had "scorched" the cocoa trees, the much higher winds of the present monsoon had done no damage. I questioned the scorching property of any Ceylon wind (although the action of wind laden with sea-moisture on young coconut palms looks exactly like that of fire), and an experienced V. A. who was present hrewdly suggested that the cocoa plants were this year better grown and so better able to resist the wind.

Cinchonas like cocoa plants will be all the better of the shade and shelter of coffee or tea when young, and a gentleman, who has had considerable experience in Ambagamuwa, Dikoya, Maskeliya and Dimbula expressed strongly his opinion of the advantage of planting cinchonas amongst tea. Certainly in my own case *cinchona officinalis* planted amongst tea looks wonderfully fresh and flourishing. There seems little doubt that the far reaching taproot of the tea plant drains the soil of superfluous moisture, while the rootlets open up the soil. The test will be the critical period when the cinchonas are about three years old.

Coffee seen en route looked fresh and green—alas! too much so, but I have seldom seen tea and cinchona looking better. I was told that leaves of the areka palm were being tried as covering for shaved cinchona trees. Contracts had been made to deliver the leaves at any railway station at R1 per hundred, or a cent each, and the calculation was that three leaves would cover an ordinary tree. The danger, I apprehend, would be from the thickness and imperviousness of the leaves, so that fermentation might be set up. Mana grass has many merits: amongst the rest that no string is required to tie it on the trees. "Wild ginger" or cardamom leaves answer well, and I have seen the leaves of gladioli thus utilized. Up at this elevation, besides coarse grasses in open spaces in the forest, there is abundance of the dwarf bamboo, which probably would answer as a covering.

The appearance of tea at between 5,000 and 6,000 feet altitude, here, is all that could be desired, and the use of machinery is increasing. I wonder if a fellow-passenger was correct in his assumption that the soil of Ceylon, unless manured, would never produce tea with the *strength* of the Assam product. Delicacy of flavour, however, is the desiderated quality in tea to be used alone, and that Ceylon tea possesses.

The carpenter on this estate who has taken a contract for making tea chests is doing a little in tea dealing. After purchasing several parcels of coarse, broken leaf at 6d per lb. he has just got 1 cwt. at 5d. The tea, although it "liquors" excellently, would scarcely sell in the London market, so that the transaction pays us, as we do not supply lead, &c., and it is of very great importance that the consumption of tea by the natives should be encouraged. I trust, therefore, the buyer will obtain such profit as will lead him to more extended transactions. The popul-

ation of Australia is exactly the same as that of Ceylon. But, while over twenty millions of pounds of tea are consumed in Australia, the consumption in Ceylon is not much over 100,000 lb. ! Now that the native patches of coffee have so largely gone out, those accustomed to coffee ought to take to tea. If our $2\frac{3}{4}$ millions only consumed $\frac{1}{4}$ of a pound per head per annum, that would be nearly 700,000 instead of 100,000. If the consumption of tea could be increased and that of arrack lessened seven-fold, the change would be for the better for all classes. I cannot doubt that the Hindus will yet rival the Chinese as tea drinkers.

The blue gums grow rapidly as a general rule, but at high elevations, where they are exposed to cold wind and drizzle, they suffer from what I take to be a species of leaf fungus which spreads to cinchonas, tea and other plants. A very considerable proportion of the gums get broken or blown down in the high winds, being topheavy and often with but a slight hold of the ground. Tea is being pruned as well as planted, and there is at present no sign of the moth which does so much harm to the tender flush. The climate is today perfection—cool without being cold, even at 5,800 feet altitude.

Lindula, July 23rd.

I suppose it is due to the unusually wet monsoon that the species of tea-blight which affects the older leaves, turning them to a rusty copper colour, deepening to dark brown as the leaves wither and die off, is so badly prevalent. The Australian gums are innocent of any responsibility in this case, for the disease was seen long before the eucalypti were grown on this estate. Many years ago, I sent some affected leaves to Dr. Thawites, but he made light of the matter, indicating that discoloration of some of the older leaves of the trees would not affect their general health. So it has been generally, but this year the blight has caused the withering and dropping of a large amount of foliage, especially in the case of trees reserved for seed-bearing purposes. Much more serious enemies as yet, however, have been the symplox, round the stock and root of which from two to a dozen bushes sometimes die, and the moth which, in warm weather, attacks not the mature leaves but the tender flesh, much of which it ruins.

There is always something for the planters to contend against Strange to say the unusually wet weather has not developed bug to any extent; *Hemileia vastatrix* seems in abeyance, and grub, " which swept up, in the course of the past four or five years, from Nanuoya estate through Palmerston, Ritnageri, Somerst, Langdale, Avoca, Lorne, and Abostford to Maha-Eliya is departing in the same order, the last-named estate alone being now badly affected. At this juncture the coffee planters' old and much dreaded enemies the rats have appeared, and recommenced their diabolica work of destruction, taking off the primaries close to the stem, with a cut as clear as if a sharp *pruning* knife were used. If the rodents are attracted by hunger, and I believe some of the *nilu* (*strobilanthus*) is flowering, the strange thing is that they do not eat the branches they sever. I can as yet only speak of the wood-rats on Dessford and Abbotsford, but I suspect they will diffuse their attentions. A good deal of rain fell this morning, but there is some promise of a fine afternoon. Cinchonas seem to be flourishing as they never did before, up here.

Lindula, July 24th.

This is a fine planting monsoon, and I suppose advantage has been and is being taken of the moist weather to push forward the plantingof tea, cinchona and shelter trees, everywhere, and, at the lower altitudes, cocoa, cardamoms, rubber trees, &c. With all the rain falling up here, the temperature recently has been so mild that the tea bushes are shewing decided symptoms of a "flush," which may be gathered from some of the bushes before they are pruned, an operation to which it is melancholy to see from 2 to 6 feet of most luxuriant green and golden growth sacrificed. This in the case of best Assam hybrid, the growth of which between 5,000 and 6,000 feet is so marvellous, that I can well conceive the use of superlatives being necessary to describe the progress of the plantations in the low, hot valleys near Awisawella, Kalutara, Yatiyantota, &c. By the way, the appearance of the flourishing tea plantation which has taken the place of coffee on a portion of what was old Sinhapitiya estate, near Gampola, the first coffee plantation opened in Ceylon vividly reminded me of a similar but much more extensive expause of undulating tea cultivation, in the valley of Sinegar, Java, the property of Mr. Kerkhoven. The Java elevation is only 1,500 feet, that of the Dumbara valley, and my first sight of 1,200 acres of closely cultivated and evenly pruned tea suggested the idea of a mimic sea, with wavelets of vivid green. Mr. Kerkhoven believes in the "hedge" system of culture, his China plants being put down at distances of 2 feet in the rows (he believes in even closer planting) and 4 feet between the rows, to allow of the careful hoe and even plough culture which is possible on his land. That our Ceylon tea must ultimately be manured is evident from the fact that the Java estate, although formed on rich lava soil, is copiously treated with fertilizing matter, largely manure from the proprietor's extensive horse stables. But I must refer to my notes (which I have not here) for a full account of the Java tea culture, as also for the incidents of my most interesting visit to the establishment at Buitenzorg of the gentleman whose death I regret to see recorded in your latest news from the Dutch colony—Mr. J. E. Teysmann. To his courtesy I owed my first sight of an extensive plantation of cocoa in full bearing, the only one in Java, I believe ; while the sight of his large collection of rare animals was a great treat. The apes and monkeys were especially numerous and varied, some of the former painfully human-like in visage. I there, for the first time, saw the anomalously tusked, hog-like creature, described by Wallace as almost peculiar to Celebes. But what most astonished me were the breeding cages of multitudes of insects of the mantis tribe, some enormous in size, curious from their resemblance to leaves and twigs and many distinguished by gorgeous colouring of vivid scarlet and orange. I fancy Mr. Teysmann never recovered the shock of the death of his wife, for whom he was mourning when, in company with his successor in the Botanic Gardens, Dr. Treub, I visited his interesting place. No doubt my visit to Java took place at a period of abnormal drought, but I came away with a settled conviction that, whatever may be the case in regard to coffee, Java has no advantage over Ceylon as a tea-growing country except that of having earlier adopted the enterprize. Our hot, moist climate and evenly distributed rainfall, and especially our command of labour, more than compensate for a soil somewhat inferior in fertility. Although neighbouring tea bushes get affected by the blight which I have noticed as attacking the leaves of eucalypti planted above 5,000 feet here, the tea does not seem to suffer to any extent. The case is very different with cinchonas, which, to the lee of the gum trees especially, suffer much : not only the leaves but occasionally the top twigs withering, while a few cinchonas have been undoubtedly killed by the disease. After emptying our present nurseries, therefore, we shall plant no more gums above 5,000 feet, and we have learned by experience that it is unwise to plant those trees in soft ground by the sides of roads or drains, as they do not seem to send down tap-roots, get top-heavy, with luxuriant foliage and fall down in numbers, not merely in windy wea-

ther, but when the earth is soaked by rain. Grevilleas are preferable in every respect except, perhaps, rapidity of growth: they and the "black wattle." The latter tree is specially liable to attacks of loranthi, parasitic plants allied to the mistletoe, but these could be cleared away by coolies armed with long poles to the ends of which crooked knives or sickles are attached. Monkeys still continue occasionally to break off the tops of cinchonas near forest with their forehands, but latterly elk have become much more destructive and must receive attention. As I am always ready to *give* information I now venture to ask for the experience of those who have allowed tea plants grow up as seed-bearers. Ours have been left absolutely to grow at their own sweet will some for seven years. But probably a certain amount of pruning and perhaps topping (?) would improve the quality as well as increase the quantity of the seed? Some of my trees are over 20 feet in height. Would topping be beneficial as well as thinning out the smaller branches?—P.S.—At 3 p.m. the rain is heavily heavily, 0·62 of an inch having fallen since the record of the previous 24 hours was taken, and the coolies have had to be knocked off.

The Tamils are valuable labourers, but only when well looked after. In this connection I may notice a letter which my good friend Mr. St. George Caulfeild has addressed to the *Queenslander*, and in which he claims special belief in his testimony favourable to the Tamils as labourers, because he is a superintendent and not a proprietor. Now why, may I ask, should the testimony of a superintendent as regards the character of the coolies be better worthy of belief or less suspicious than that of a proprietor. Superintendents are constantly passing into the ranks of proprietors—Mr. Caulfeild, doubtless, hopes to undergo the transformation. Will his testimony and that of other men who have passed from the position of superintendent to that of proprietor become valueless or less trustworthy with their rise in life? Until an answer is given, I must consider the problem as much "one of the things which no fella can understand" as the compositor's reason for making me write of tea *flesh* instead of flush. Perhaps the printer had heard that tea to hard-working milliners and others is not merely a stimulant but a very good substitute for flesh-forming meat. The vulgar idea that tea is injurious to weak or consumptive people has in countless cases resulted in the cruelty born in ignorance. One of my earliest recollections is that of a poor consumptive patient who instinctively longed for the comfort of a cup of tea, which she said her husband out of kindness—most mistaken kindness—refused to let her have. To the vast majority of those who use it, tea is a boon, and the more who can use it the better.

INDIAN COOLIES. CINCHONA.

TO THE EDITOR OF THE "QUEENSLANDER."

SIR,—I am a Ceylon planter of ten and more years' experience, and I have lately had my attention much turned towards Queensland, where I have relatives. I have been principally interested in the procuring of Tamil labour for Queensland, and have read with interest articles in the Queensland papers on this seemingly vexed question. I hold that the extra value to be obtained from your waste lands, both public and private, by the increased cultivation rendered feasible by the introduction of black, cheap, and *good* labour, will in time tend to make more work in many ways for the whites, who now object to the introduction of such labour. From all I hear and read, I gather that the available fields of Northern Queensland must and will lie waste unless you get a sufficient quantity of cheap black labour, which your kanaka labour evidently is not. My experience of Tamils extends over eleven years, and I find them capital workers. Mind, I write as a paid superintendent, and not as a proprietor, so my words can be relied upon. With such vast extent of available lands, Queensland ought to be a fine field for hard-working men willing to rough it for a time.

I send you by this mail a packet containing 1 lb. of *Cinchona officinalis* seed, to be used as you see fit. If it had not been for the cinchona enterprise out here a good many planters would have gone to the wall, owing to bad coffee crops. The public were at first most unwilling to embark in the new enterprise, but now it is largely engaged in, and has turned out a first-class cultivation. *C. officinalis* will, I believe, suit your climate best, as out here, owing to excessive wet, it dies out in large patches, with cankered roots. You should strongly advise your fellow-colonists to give the cultivation a trial, and should it thrive with you it will run your other products hard, as the demand is steady, and indeed above the supply.—I am, sir, &c., H. ST. GEO. CAULFEILD.

Ceylon, 24th April.

A CEYLON planter (Mr. Caulfeild), of more than ten years' experience, has kndly forwarded to us by mail 1lb. seed of *Cinchona officinalis* for distribution. His reasons for doing so will be gathered from the letter accompanying the seed, which will be found on another page. Mr. Caulfeild's opinion and remarks are in perfect agreement with the reports which appear from time to time in our exchanges from India. There the cinchona is largely cultivated, and various methods are in use for stripping the bark so as to save the trees for future production, and different varieties are grown according to the locality. It may be well for our readers to bear in mind that the tree is decidedly tropical, and cannot be expected to thrive except in the northern districts; there, however, without doubt it will be perfectly at home. We have to thank our thoughtful correspondent for the fine parcel of seed we have received, and which we shall be happy to distribute amongst those of our readers in the North who will give it a fair trial, if they will make early application for the same.—*Queenslander*.

LOW-COUNTRY PRODUCTS IN CEYLON.

LIBERIAN COFFEE AND HEMILEIA VASTATRIX; CROP; COCOA; WAX-PALMS; CEARA RUBBER; CRICKETS.

Henaratgoda District, 8th July 1882.

June was wet up to the 23rd, when a fortnight of dry weather set in, cloudy with strong wind—not reasy, teasy, easy wind, but rairing, taring, raging wind, that tears branches from the trees, and carries them for many yards. The wind had calmed down for a couple of days, but broke out again yesterday, in one of the fearful squalls to which our district is so liable. I was fortunate, in having evacuated the kajan hut I have occupied for three years, for it came down by the run, a few days afterwards, burying one coolie in the ruins; luckily none of the heavier sticks came on him, and he was rescued with little or no damage. I thought I had chosen a spot for my bungalow, sheltered from both monsoons, and so it is, but the wind perversely persists in coming either from the north-west or south-east. In fact, the wind has not settled for a day to south-west, since the present monsoon opened.

I am sorry to say that the fungus is extending on the coffee of all ages, from nursery plants upwards, and many of the larger trees, that hitherto appeared fungus-proof, are contracting pinspots. I cannot now say, that there is one variety, on the place, that remains unaffected in all its individuals, and I begin to fear that we have not a kind with an absolute power of defying the enemy. I have three ways of

treating the disease, on plants from one year old downwards. A fine healthy plant, with only a few leaves affected, I strip of all diseased leaves to give it another chance; a plant from eight to twelve months with a stem as thick as my finger, and all its leaves affected, I cut down; and, where a very young plant has contracted the disease, I pull it up altogether. I already know that stumping is little or no good in the way of getting a healthy shoot, but one here and there succeeds, it is worth while to give it another chance. When the fungus attacks a very small plant in the field, the best way of dealing with it is to destroy it at once; it never will be a healthy plant if left, and will always be a fresh centre of infection as long as it lives; the chances are, however, that it will die after shedding an immense crop of spores.

The young plants injured by the caterpillars have mostly opened fresh leaves, but the check has made them particularly liable to contract fungus, and I am daily pulling them up, as it manifests itself. I could not detect it on the plants when put out, but it was probably latent in the nursery, else how could it appear so suddenly on the newly cleared land?

I have a very small crop to gather this month, the first-fruits of the thirty-two months old trees; its characteristics are great thickness and toughness of pulp, a great quantity of very tenacious slime, and thirty-five per cent of peaberry. A picked sample of the largest dry parchment, 640 beans weighed one pound, of the smallest it took 1,200; and of the unsorted 850. The average of the largest and smallest gives 920, but there is no more of the large and middling sized than of the very small; the peaberry gives more of the very small than the doubles, trebles are very rare in Arabian coffee, but they are not uncommon in Liberian. Of course, these facts and figures decide nothing: I only record them while they are fresh, and I have only a few handfuls of half dry parchment to deal with. When I next write, I will be able to tell more about it from further experiments. For the last two months, I have been gathering a few berries that dried on the trees, and, having cleaned and thoroughly dried them, I find it takes 1,760 to make a pound, and perhaps a day or two more in the sun may call for a greater tale to make up the weight. There are a good many 'ifs' connected with the future; if we can get rid of *hemileia vastatrix*, the if of ifs, if we can eliminate all but the best varieties, if we can place them in congenial soil, and if we feed them year by year with as much or more of the elements of fertility as we remove, there is a fortune of R10,000 in 20 acres of such Liberian coffee. This is however a mere dream of what might be, if conditions were different from what they are; at the very foundation of such a system, we must have no *hemileia*; we must either succeed in establishing a variety that will absolutely resist it under every circumstance, or we must have some means of effectually combating it. Till one or other of those objects be attained, we have no security for our investments in this product. We may, in favourable cases, recover the original outlay, but while we see the pest surely if slowly advancing, absorbing, one after another, our most hopeful plants; when we see that the most vigorous tree that has once admitted a pinspot is lost to profitable cultivation, after a struggle of longer or shorter duration according to its essential stamina. It is true that Liberian coffee plants have lived and flourished for years in an atmosphere laden with the germs of *hemileia*, but when we see those plants stricken at last and rapidly succumbing, we begin to lose confidence and seriously consider, whether, under the circumstances, it is a prudent course, to continue extending the cultivation or to rather wait and watch, for more knowledge to guide our action. There is no doubt, that, of all our new products, Liberian coffee is the foremost, but for this one drawback, the liability to the fungus. In the direction of an effectual remedy, our hopes must be rather cold all round, but with the certainty that among the vast variety there are degrees of liability to contract fungus, we may do much in selecting seed from those plants alone, that have stood the test of years and possess other good qualities. In my own charge, I have still less than ten per cent of affected plants, but my trouble arises from the fact, that the percentage is increased by every spell of wet weather, and the instances in which it has been shaken off are few and far between, and recently spots have shown on some of my pet plants. I have at length a few pods of cacao, on the few trees that are just three years old, and even those a few months younger are trying hard to bear. This plant, so hard to establish, seems hardy enough, when it gets up, to two and a half or three years, on tolerably sheltered spots, but on a gravelly soil, or an exposed situation, it simply will not do any good, though it has great tenacity of life, and sometimes makes a start, after lingering between life and death for a couple of years.

The seed of wax-palm have been in the ground for three weeks, and on examining some today I find no change whatever. A small nursery of cloves (only forty seeds down); and I am waiting for a thousand nutmegs, to commence that branch of cultivation. I cannot speak very favourably of the cardamoms, but vanilla seems to have found here exactly what it requires to thrive on. Ceará rubber is already in some cases nearly twenty feet high; and I will within the year have my own seed for extending its cultivation. I am by degrees getting up fruit trees. The pumalo, the citron, the orange, and the lime: somebody—I forget who—promised me lemon seed. The citrus tribe have their special caterpillar, and very difficult to rear, to the height of three feet, when they are pretty safe. I have only two or three mangoes, as all but the best kinds are mere cumberers of the ground, and I wait till I can get the best kinds. The Kew pine seems destined to supersede all the inferior kinds. I have only a few plants now, but hope soon to enlarge my stock of this magnificent product. I have breadfruit, custard-apple, soursop, namnam, pomegranate, *coca*, papaw, rambutan, &c., &c. I have not gone in for a vegetable garden, and ornamental plants, but these may come hereafter, with some leisure to attend to them. "Jock," said the dying laird of Dumbiedikes to his son, "when ye have nacthing else to do, ye may be aye sticking in a tree: it will be growing when ye're sleeping."

A lowcountry estate should grow some of everything, that can be profitably cultivated, that conduces to the comfort of the resident, or is even pleasant to the eye. With half a score of different products, cultivated on one property, there can hardly be such a general failure of crops, or depression of markets, as to affect them all at the same time. If there be a poor crop of coffee, the tea may be a good one; there may be a failure of the cocoa, but the rubber may bleed well; the bad fruit season may be a good spice one, and *v. v.* It is not easy to find in Ceylon a hundred acres of land of uniform quality but by multiplying our cultivated products we can suit all qualities, and put Ceará rubber or wax-palm, where nothing else will grow.

A writer in the *Observer* of 13th July accuses me of being behind the age in those days of Seowen's transplanters, and coffee seed at a rupee a thousand in that I have been using baskets, to rear my plants; and advises me to sow seed enough for the percentage destroyed by crickets, as well as for my own wants.

I answer, that for upwards of two years the per-

centage of loss from crickets would have been precisely one hundred, in open nursery beds, and but for the fortunate discovery, that the plants were comparatively safe in baskets, the attempt to rear them here must have been abandoned. Furthermore, the seed I had to deal with was not obtained for one rupee per thousand, some of it having cost as much as twenty rupees. If I expressed myself, so as to lead an "old friend" to believe, that I meant to use baskets, when or where there were no crickets, I am sorry for it, as I never intended to convey such a meaning, and if my critic will visit me I will show him as fine a mersery in the open ground, as heart could desire, the army of mole crickets having failed to put in its half-yearly appearance last March. I remain in total ignorance of the conditions, that rendered this place, for two and a half years, the favourite breeding ground, of myriads of mole crickets; as of the change of conditions, that has led to their almost total disappearance. I do not hold any one a competent judge of the necessity of the precautions taken, to counteract an evil, that the critic has never had to deal with, on an equal scale. Let my old friend one day plant out 2,000 plants, and find one half of them cut off next morning, and he will probably feel less ready to find fault with the doings of those who have had to deal with such mischances.

I had not one of my last planting cut in the field, but I have lost some hundreds from caterpillars: quite a new experience.

TOBACCO-PLANTING IN DELI (SUMATRA).

(From a Correspondent.)

27th June 1882.

I am glad to be able to report that cholera is now on the decrease. A short time ago this fatal epidemic seemed to have been raging in all parts of the country, sweeping away the "Celestials" and Bataks in great numbers. It was a sad time indeed for tobacco planters, who could ill afford to lose their coolies just about the middle of the planting season. However, we are now pretty nearly rid of the enemy, and the drooping spirits of the planting community are beginning to look up again. Much is owing to the recent heavy rains we have had in arresting the epidemic, and still the cry is for more rain, being as it is so very beneficial to the growth of tobacco. This is the only product cultivated to a great extent and the prosperity of Deli has been hitherto mainly due to the success which has attended its cultivation. All the planters are looking forward to "bumper crops" this year. Cutting has already been begun on most of the estates, and there are not a few who hope to make from 12 to 14 piculs per cooly. The advices which have lately been received from Amsterdam show as usual that most grades of Deli tobacco have met with a favorable reception in that market: the exception being broken leaf, which is now in little demand. So far everything looks promising for the planters, and should the strong winds we are having just now from the south-west do no damage, all will be as desired.

I do not think it will be long before the planters here take to cultivating other products, besides tobacco. The long range of hills in the distance offers a tempting prospect to those who are contemplating the cultivation of coffee, &c. The soil is rich and the climate delightful. But unfortunately the hills are forbidden ground to the "Orang putih"; notwithstanding this there seems to be a steady advance made on them by two enterprising Dutch gentlemen, an advance which, if properly directed and carefully assisted by the ruling powers, may ultimately result in a good portion of the hill-country coming under cultivation. At present all is but a wilderness of fertility, awaiting the busy hand of the planter.

COFFEE CULTURE IN CENTRAL AMERICA AND MEXICO.

(From the *Rio News.*)

The following remarks upon coffee culture in Mexico and the Central American states, are from the pen of M. Thiersant, French consul in Central America, translated from the *Journal des Economistes* into the New York *Commercial Bulletin* of March 3rd:

"When the railways now in course of construction are finished we may look forward to great improvements and extension in the cultivation of coffee in Mexico. The present export is estimated at 4,000,000 pounds, almost exclusively purchased for the United States. The culture was introduced in 1828, and has now extended to the states of Chiapas, Colima, Michoacan, Vera Cruz, Talhzeo, &c. Colima coffee is well known in all markets. The Government and planters are doing everything in their power to extend the cultivation and improve the product. An agricultural Society is established in the city of Mexico, to which most of the planters belong, and a weekly paper is published containing their observations, etc. Here, also, however, plants that are five years' old are attacked by a disease termed *chahuistle*. It is especially observable in dry and worn-out soils, or on sun-exposed slopes.

"Costa Rica began to grow coffee in 1820. In 1830, the immense tracts to the south of the capital were sold on condition that only coffee trees would be planted. Still, the cultivation has only slowly extended until recently. At present, from 250,000 to 300,000 quintals are annually exported. The soil of the country is extremely fertile, and the climate most favourable to the coffee plant. Labor and capital are, however, wanting, and roads and means of transport in the interior very deficient. Almost the whole foreign trade of the country is done through the port of Puenta Arenas, on the Pacific, and to this port there is only one line of communication, and even this is only practicable in the dry season, from December to March. The freight from the port to the capital is often 80 piastres per ton for a distance of 18 leagues. Only one-half of the 300,000 bags harvested can be exported, on account of the bad roads. A railroad from Limon on the Atlantic, which is to connect the port with the principal centres, has been in course of construction since 1870, but is still far from being completed. The total length will be about 115 miles. The soil has been exhausted in many instances, and manuring will be requisite. There is a very suitable zone for the cultivation of coffee which is traversed by 70 miles of railroad, and which can be connected with the port of Limon.

"Nicaragua began to grow coffee in 1848, and now some four and-a-half million of pounds are annually exported. The same hindrances alluded to above are here in force. Lately, new plantations have been made and the construction of a railroad had been begun. The country is of extraordinary natural wealth, but its fields are deserted, its forests silent and its harbors empty. The inhabitants seem to have been placing illusive hopes on the construction of a trans-oceanic canal.

"Salvador now ships 200,000 quintals—a quantity which may be doubled within a few years. The cultivation was almost entirely confined to the western part of the republic, but is now extending to other parts. Some plantations have been lately made on the heights near the *volcano* of San Miguel. A foreign Company has been given a concession to build a line

of railway from Sonsonate to the port of Acajulta. The population is laborious and peaceable, and the country on the road to progress. The coffee trees were attacked last year by an insect, but a very good remedy has been found in the use of tar.

"Honduras so far has scarcely grown enough coffee to provide its own wants, and the article known as Honduras in other markets is Guatemala. The government has passed a measure to exempt all coffee plantations from taxation during ten years, and it is believed that the imports of the state, amounting to 9,500,000 piastres annually, may be covered by coffee exports within two years ; 5,000,000 coffee trees have been planted. The want of hands, that is of well conducted Europeans, and the eternal political disquiet of the country are great drawbacks.

"Guatemala, bathed by the two oceans, and with the magnificent port of Santo Thomas de Castillo, has also a fertile soil and salubrious climate. Coffee constitutes its staple product today, and the shipments are now 289,762 quintals. Before 1835, very little was grown. Several railway lines are now being surveyed or in process of construction. The compulsory labor of the Indian is spoken of as a legislative measure. The insect enemies of the plant are numerous, but not so dangerous as in other places."

The writer attributes the present state of the coffee market to over-speculation, chiefly the work of a clique, who began operations in Frankfort on the Main in 1868 ; also to the over-production in Brazil, and to the effects of the commercial crisis. The fall in prices in the United States added to the difficulty, The present prices, M. Thiersant thinks will hardly change for the better, unless through speculative process ; "but then," he adds, "the coffee market has now become a true speculative market."

[The quintal is equivalent to 100 lb. Our readers will notice the frequency with which disease in Coffee, chiefly of insect origin, is mentioned.—ED.]

PLANTING ON THE HILLS OF CEYLON.

THE RAIN: "TOO MUCH OF A GOOD THING"—THE GUM-TREE LEAF DISEASE—GROWTH OF THE TREES—"HYBRID" VERSUS "INDIGENOUS" ASSAM TEA—HYBRID CINCHONA—RATS, GRUB, AND LEAF DISEASE—FRUIT TREES—FODDER GRASSES.

LINDULA, 27th July 1882.

What the Scotch proverb says of the "fox's bairns," viz. "the aulder the waur" (the older the worse), can truly be said of the S. W. monsoon of 1882 in its closing days. Good planting weather is very good, but one thinks of the inebriate who was audibly praying that the Virgin would help him on to his horse. A passer-by gave him such a lift that he fell over on the other side. With unjustifiable expletives he exclaimed: "When you are good you are too good!" Genial rains and gentle winds are excellent, but when both rain and wind unite to cause such a "pelting pitiless storm" as to keep or drive planting gangs indoors for days in succession, one feels inclined to say of moisture, that, like other good things, there may be more than enough of it. Without moisture there would be no vegetation, but moisture in excess is almost as injurious to vegetation as is the liquid with which the toper too frequently "moistens his clay." Disease results in each case, and the following reply to my queries as to the insect or fungoid character of the blight-spots which attack the leaves of the eucalypti up here, and from the gums spread to cinchonas and other plants, favours the inference that excessive moisture may produce diseased tissues, without the agency of insect or fungus :—

"I have received your letter of the 22nd instant, with various diseased leaves. The latter I have examined microscopically, and cannot find that their diseased state is attributable to the attacks of insects. They may have suffered in some measure from fungi, but I am uncertain whether the injury is entirely owing to attacks of that nature. Balfour, in his *Class book of Botany*, tells us that the common cause of disease in plants are improper soils, ungenial climates, frosts, rains, storms, parasitic plants, insects and wounds of various kinds, and that plants grown in an ungenial climate and soil are very liable to disease. He further says that there is no evidence of plants being acclimatized by a process of cultivation. Thus, there is a wide field for investigation. The rats that have made their appearance, will probably not remain long. I am sorry I am unable to throw more light on the subject of the diseased leaves." The comfort, of course, is that a climate which in particular seasons and temporarily may, from excessive moisture for instance, be rendered unfavourable to particular plants, may, on the whole, be eminently suitable to their vigorous growth. That the climate here, with all its moisture, so different to that which generally distinguishes the arid habitat of the eucalypti in Australia, is a suitable one for the gums, notwithstanding occasional attacks of leaf disease, may be inferred from the fact that around me, as I write, are blue gums which have attained a height of over 60 feet in five years : the average rate of growth being thus 12 feet per annum or 1 foot per mensem, even at an altitude of close on 6,000 feet. It is not injury to the gums themselves, I fear from the small pock-like spots on the leaves so much as the harm done to the more delicate cinchonas, especially the calisayas and ledgerianas, by the infection which spreads to them and which affects injuriously not only the leaves but the tender tops, which canker off. The much more robust tea plants can take care of themselves when attacked by the gum spots, and even the more serious blight peculiar to themselves does not seem seriously to affect their strength : they lose foliage but are not debilitated like the unfortunate coffee trees under the enfeebling attacks of *hemileia vastatrix*. To verify my statement that some of my seed-bearing tea plants were over 20 feet in height, I had one of those in my seven-year old grove of best Assam hybrids tested by actual measurement this morning. The ascertained height from the ground to the top was 22 feet, and there was near by one about a foot higher, while it is believed that a tree in a distant part of the estate is loftier still, probably 25 feet high. I should like to hear if taller tea trees exist in Ceylon, and what their ages are. The rate of growth established in the case of the one measured today is 3½ feet per annum, or say one-fourth the rate at which the Australian gums progress. I think I have read of tea trees 40 feet high in the jungles of Assam, but I should like the test of absolute measurement applied to trees so described. The alleged altitude is certainly not improbable as my own trees look as if they had by no means ceased their upward growth. Some of the stems are about 4 inches in diameter, that is 1 foot in circumference near the ground. My big trees are all from seed of good hybrid Assam, which, with us here, has given far better looking and more vigorous plants than those resulting from seed of "indigenous" plants, charged at the rate of R150 per maund. I do not feel justified in giving it any further trial, while hybrids approaching the Assam parent are so superior to either the large leaved but delicate "indigenous" Assam, or the dwarf China plants, with all the varieties between. Col. Money, amongst others, deplores the contamination

of the native Assam tree by the introduction of the China plants in Lord Wm. Bentinck's time; but the almost universal consensus of opinion amongst Indian planters is that the result of the connection between the Mongolian and the Indian plants has been most beneficial, by the production of a hybrid, which is copiously fertile, more robust than its Indian parent, and more prolific of leaf than either that or the China parent. It would seem as if the intermixture of the various species of cinchonas here and in India was likely to yield similarly beneficial results in the production of a hybrid, more robust than ledgeriana while approaching it in wealth of alkaloids, quantity of bark making up for any possible deficiency of the latter, if deficiency there should ultimately be. I have reason to be glad that the "hybrids" are approved instead of being condemned, for a gentleman who travelled with me from Colombo informed me that of plants from officinalis seeds received from this estate 30 per cent at least turned out to be hybrids. The same pleasure which he felt at this result I have experienced in seeing the thousands of robust, vigorous-growing trees here, the result beyond question of a cross between our succirubra and officinalis. Hybrids between succirubra and calisaya promise equally well. It does not seem as if the rodential attack was to be more than sporadic, and as for the fathers and mothers of the grubs, the appearance of a solitary beetle during a long excursion today was considered phenomenal. Having since I wrote passed twice close enough to Maha Eliya to have a good look at it, and up to the top of the valley as far as Calsay, I may say that even the effects of "grub" are now few and far between. While having pleasure in stating this fact, it is quite a new idea to me, although it has been propounded, that to say that grub or the effects of grub existed on an estate might injure the character of a superintendent. Human nature is unreasonable enough, but we should like to see the moral monster who held the superintendent of a plantation of coffee responsible for the ravages of grub or hemileia, or the manager of a vineyard for the deadly effects of phylloxera. That grub as well as leaf disease have existed and inflicted incalculable injury on coffee in *all* the estates in this valley as well as in other parts of Ceylon, is a simple matter of fact, to be greatly deplored. The almost total disappearance of both would be matter for unqualified congratulation, if we could only be certain that each had said "farewell forever." We can but hope for the best, while, personally, I regret that I did not follow the advice given by "old Thwaites" in Nuwara Eliya in 1870, to plant tea and not coffee on the property marching with Maha Eliya in which I am interested. What with leaf disease, rats, grubs, debilitated bushes and bad blossoming seasons, I have never had but one decent paying crop of coffee. It may do better, and I hope it will, for the sake of those more entirely dependent on it than I am. But I am doing now what I wish I had resolved to do a dozen years ago,—devoting my first attention to tea, my second to cinchonas. From the first, however, I neglected neither, so that now I am able to extend largely the cultivation of both, and both promise exceedingly well.

Orchard fruit trees obtained from England and Australia have been generally disappointing, from want mainly no doubt of proper attention by a good gardener, such as is so common in India, so scarce in Ceylon. In most cases of peaches and nectarines, the grafts died off and the stocks and sprouts from them flourished. A few apples have appeared occasionally, however, and this morning a couple of bunches of two distinct kinds were gathered to save them from the effects of the weather and the attentions of the coolies. I send one of each kind,* and you will see that they give promise of good results to those who could bestow proper attention on fruit growing, in pruning, digging, manuring, &c. *The* fruit which flourishes on coffee estates is the citron, of which bushels can be obtained. They might be acceptable to steamer passengers, if but for the manufacture of cooling drinks. Of all the fodder grasses, guinea grass is the most acceptable to stock; but at high altitudes *reana luxurians* flourishes much better and yields large returns of stalks which, if the cattle do not take kindly to them, could be used to cover cinchona trees. Amongst its other merits is that of growing on subsoils bared by landslips as readily as mana grass. Today I saw fine plants thickly growing, the result of seed scattered on such a bared precipitous spot. As sugarcane is grown for fodder up to 7,000 feet in Central America, it ought to do well here, and I believe an experiment was tried on Mattakelly.

CULTIVATION OF CORK.

The cork tree is an oak *(quercus suber)* growing in the south of Europe and especially in Spain and Portugal, where it attains the height of thirty feet. No oak is indigenous to Ceylon, "the Ceylon oak" being a misnomer, and the few plants of English oak introduced have been very slow of growth and have degenerated into a bushy form. Even if the cork oak could be established on our higher hill ranges, it would need, under the influence of our tropical climate, to come to maturity much earlier than it does in its native habitat, to satisfy a desire for quick returns. From the short notice in the new edition of the *Encyclopædia Britannica* we gather that the first stripping does not take place until between the 15th-20th years, and such bark is only suited for ornamental work in conservatories or for tanning. The bark is subsequently removed every eight or ten years, for 150 years, improving with each successive period. A trial of the cork tree might be made, but scarcely on a large scale.

CALCUTTA TEA SYNDICATE.

Calcutta, June 20th, 1882.

DEAR SIR,—By desire of the Committee of the Tea Syndicate, I issued a circular on the 15th April last, and, having since received important letters from the New York and Melbourne agents, I now wish to draw your particular attention to certain portions of them.

AMERICA.

Under date of 24th March, the New York agents write that inquiries which come from Canada, Baltimore, and the Far West, places hundreds of miles apart, show that there is more interest taken in Indian teas every week, and they are quite confident that a general curiosity to have a few of them would soon lead to deliveries of considerable importance, if they had the teas to offer. In a general way, they would advise shipments of teas costing about 8 annas, and a few at 10 annas, giving preference to small, black, well-made leaf, free from dust, and of flavoury liquor, rather than to those with much pungency.

On the 1st April they write that the quantity of Syndicate teas offered at the weekly auctions might be gradually increased, if they had a sufficient supply to keep the tea before buyers, up to receipt of the first shipment of new tea. As, however, they

* These can be seen at our office.—ED.

had only 950 packages unsold, they proposed to spread this quantity over sales in April and May, but they would have none to offer in June. New China congous reach New York in small quantities about the 20th to 30th July, and are in supply about the end of August, before which latter time it is hoped our first shipment of new season's teas will be on the market.

Writing on the 15th April, they say the experience of Indian teas in New York will doubtless be like that in other countries, viz., that the safest business will be in medium grades, or teas rather below these, but it may be politic, in order to make a favourable first impression, to ship finer grades. The New York agents have lately been selling most of the teas by auction, only offering the choicest kinds and the broken teas at private sale, and they say, under date 21st April, that they see no reason to regret having resorted to auctions, for the teas continue to bring very fair prices, and the chances of their coming into general use are very much increased by the prices at which the trade have secured them, as well as by the fact of their having gone into the hands of many more buyers. Up to that date 2,646 packages had been disposed of to 58 different dealers.

Acting upon the very strong recommendation of the agents in New York, as to the advantages that would probably be gained by a liberal system of advertizing in the principal cities throughout the United States, the committee have authorized extensive advertizing, and trust that shippers will now be induced to come forward with ample supplies of tea to meet the demand, which, as shown in the above extracts, now exists, and which may be expected to be materially increased when the full effect of advertizing begins to be felt.

The advices from the agents in Chicago have not lately been as full or as frequent as could be desired, but the prices obtained there for the Syndicate teas have been very satisfactory, though the progress in sales has not been so rapid as in New York.

AUSTRALIA.

The reception which Indian teas have met with in this market has been most gratifying, but our agents in Melbourne write "that supplies are nothing equal to demand, and are far short of requirements." Under date 24th April, they say that, looking carefully into the quantity of tea that can be taken by the colony (Victoria) during the coming season, they feel sure a million and-a-half pounds weight could be placed if the price did not exceed 1s 1½d per lb. in bond, and they have every reason to believe that two and-a-half million pounds weight of all descriptions could be disposed of, say of the following kinds :—

1,500,000 lb. up to 1s 1½d per lb. in bond.
750,000 ,, ,, 1s 6d ,, ,,
250,000 ,, over 1s 6d ,, ,,

The following extracts from their advices of the above date will no doubt be read with interest :—

"If prices are high with you, of course our estimate could not be realized, but, if you are in want of a good outlet for your surplus, we think Melbourne especially and the other colonial ports in smaller proportion, are open to you.

"If prices are low with you consequent on a depressed market, we should consider a good opportunity for the Syndicate (as representing the planters of India) to ship heavily to Australia, not that we think high prices would rule here, but it would give *all* tea buyers the opportunity to try Indian tea ; for the great drawback this year to general distribution has been high prices, resulting in confining purchases to few buyers well established in the Indian tea trade. Cheaper prices, however, would induce more tea men to enter into the business, and so result in a considerable gain in the long run to India.

"There is not the slightest reason that we can see why India should not command half the tea trade of Australasia, which is at present equal to 23,000,000lb. per annum ; but somebody must initiate the trade, to whom immediate profits are not of so much consequence as laying the groundwork of a large, steady, and profitable business in the future."

The members of the Syndicate are already aware that the committee are in favour of pushing the sale of Indian black tea in these new markets, in preference to attempting to ship green tea to compete with the green teas of China and Japan so much in favour in America. The shipments of green teas to America by the Syndicate have hitherto been very small, and the result has not been very satisfactory ; the prices realized for them comparing badly with the valuations made here. The committee have therefore decided not to make advances on shipments of green teas, but to continue the usual advances of 50 per cent., less Calcutta charges, on black teas shipped to America. As the experience gained of the Australian market gives more confidence in estimating results to be obtained in it, the committee have resolved to increase the advance to 70 per cent. on black teas despatched to Australia.

I would request your special attention to the statements contained in this circular, and ask you to fill up, in the forms already sent you, the quantity of tea you hope to be able to make over to the Syndicate for despatch to America and Australia during the current season. The quantity promised by returns received to date is only about 600,000lb for both markets, or not enough for the requirements of one of them, and if the hold, which, by your support Indian teas have acquired of the trade is to be maintained and increased, it will be necessary to receive much larger contributions from you. I shall be happy to supply you with fresh forms in which to fill up contributions, if you wish them.

Since the above was written, a private letter has been received from Mr. A. B. Inglis, late member of the firm of Messrs. Begg, Dunlop & Co., of Calcutta, dated Melbourne, the 18th May, in which he says :—"Don't, however, let shipments fall off, as it is most important to keep up a full supply, even at a little sacrifice in price, to get more people into the trade, until we are quite sure it is established. The consumers are everywhere taking to Indian tea, and I think all you have to do is to send plenty of it and watch the quality."

A telegram has just been received from Melbourne to the following effect :—

"Staffordshire sale successful. Pekoes higher. Send more tea."—I am, dear sirs, yours faithfully,

A. G. WATSON, Offg. Hony. Secy.

CINCHONA.—The Ooty paper states that the Government Cinchona Plantations on the Nilgiris have yielded during the official year ending 31st March 1881, a net profit of R338,156-1-1, the receipts for the year having been R434,261-1-8 and the expenditure R96,105-0-7. The financial results of the enterprize from the commencement up to the same date, show a net profit of R58,262 6-9 after the capital outlay is fully recouped. —*M. Mail.*

THE PHYLLOXERA.—A Vienna paper has received from one of the largest vineyard proprietors in Austria a communication on experiments made in a vineyard attacked by phylloxera vastatrix. The proprietor in question states that of 600 stocks invaded by the phylloxera more than 60 at once put forth new sheets and grapes. This result was attained by plentifully manuring all the plants attacked, which would seem to confirm the opinion that whilst the complete destruction of phyllexera vastatrix cannot be attained it is yet possible to prevent the stocks dying, and, even more, of causing them to produce grapes by nourishing them and by giving them strength by means of manure judiciously employed.

Correspondence.

To the Editor of the Ceylon Observer.

THE PLANTING ENTERPRISE IN JOHORE AND PERAK:—FACTS AND FIGURES.

Slim River, Durian Sa'batang, Perak, 26th June 1882.

SIR,—In your edition of the *Weekly Ceylon Observer* for 8th May last, I read a letter on Johor, Batupahat district, by "Coffee." He describes the soil as being "sand mixed with sour clay" and quite unsuitable to the growth of coffees, Arabica or Liberian, or cocoa. Such a statement from a man of "nearly 20 years experience" must more or less tend to prejudice your readers and possibly men wanting to leave Ceylon for the Straits and induce them to think the soil of the whole peninsula may answer to the description given by "Coffee," viz. "sand mixed with sour clay."

To disprove this, I forward to your office, carriage paid, by Austrian Lloyd's S. S. from Penang, specimens of soil, pressed into tins taken at various depths, and specimens of rock taken from holes dug also from adjacent streams, fair samples of the average quality of a 3,000 acre tract. One hundred acres are now felled and twenty-five planted with Liberian coffee, the rest holded and ready for planting, besides a clearing of C. arabica just put in by Mr. ————.

This place is 300 feet elevation over sea-level, running to 5,000 ft. and well watered by many heavy streams coming from a high mass of mountain land, the nearest top of which I can reach in 6 hours (4,000 ft.). Soil of excellent quality.

Health is now good, though at first opening, but moderate, much low fever. No dysentery nor jungle fever.

Liberian coffee promises to be a great success. Three trees growing side by side, put out in October 1881 as 15 inch plants, showed at the end of May 1882 a total of 34 berries set, and another (the third) blossom to follow. I do not think, sir, that in such soil as this "early maturity means premature decay." On another Liberian fourteen months planted I find 260 berries and 324 blossoms with 14 pairs of primaries. I think you will agree that this soil is nearly perfect and fit to grow either C. arabica, Liberian, or cocoa. I first came across this part of Perak in April 1879, and here determined to settle down in spite of seeming difficulties in preference to remaining in N. Perak, but though I sent description of soils and country, could not induce more than one Ceylon gentleman to follow or at least to come and judge for himself.

Communication is gradually being improved and our river opened to steam launches. Our district magistrate is building his house and station within what will be one day's walk of my place. Cooly stores are very cheap. Rice this month put down here at the rate of R2·87 per bushel, bought in Penang; salt fish at same cheap rate; dholl R5 per bushel; oil bought on the river. "Coffee" is right in saying that European food is bad. Pigs and fowls comprise the whole of the fresh meat list, but fish and turtle are brought for sale by the Malays.

The Indian labour question is still under discussion. Labour at present is above Ceylon prices. Tamils at 25 (dollar) cents per day are not cheap. I am working 21. Chinese pay better for heavy contract work, but they are not content to earn less than 25 to 30 cents per day—well worth it for roads, drains and holes: also at planting work they are perfect. I have just seen Chinese coolies put out 200 plants each for half day's work with an after loss of 3 to 5 per cent only. The greatest difficulty has been the felling, as the Malays are so utterly worthless and unreliable, content only to sleep, eat and get drunk on very strong tobacco. Whether the rising generation will prove more useful remains to be seen. I doubt it much. Slavery is far better suited to their style of work, or at least forced labour, as in Java.

Mr. T. N. Christie was here in March 1880, and was well satisfied with what he saw. He decided to take 3,300 acres in the Slim valley. If "Coffee" should again visit the Straits he had better pay this district a visit *via* Penang and Durian Sa'batang. He will, I think, be satisfied with the samples of soil sent to your office.

Mr. S. Kay Shuttleworth wished me to send samples two years ago, but, having no other certain information to give, I thought it better to wait. I give you rainfall to date since August 1879:—

	1879. inches.	1880. inches.	1881. inches.	1882. inches.
January ...	—	8·95	1·24	5·71
February ...	—	3·90	1·26	3·16
March ...	—	10·93	2·92	2·92
April ...	—	11·90	6·08	8·12
May ...	—	16·97	9·65	10·35
June ...	—	7·44	6·38	* 2·48
July ...	—	5·85	2·29	—
August ...	8·88	10·99	7·28	—
September ...	7·38	10·93	10·46	—
October ...	10·45	13·66	14·89	—
November ...	9·40	6·64	13·47	—
December ...	7·27	5·42	10·69	—
	43·38	113·58	86·61	* 26 June.

The greatest rainfall in 24 hours during these three years has been 3·00 inches. The shade temperature ranges from 64 to 90 degrees Fht. taken at 6 a.m. and 12 noon.

The box of soils cannot reach you before July. I have sent no surface soil, as I think more reliance can be placed on subsoils, and, where the latter are of this quality, the former must be of a superior class. The tins are labelled showing the different depths down to 38 inches at which taken. I pressed each tin downwards into the soil until full, so that none has been broken before entering the tin. I enclose my card. LEICESTERSHIRE.

P.S.—After writing this I received a letter from the Resident, in which he says:—"The cooly ordinance is passed."

CAPT. COX'S LEDGERS IN WYNAAD:—ANALYSIS OF BARK BY MR. HOWARD.

Cherambadi, July 10th.

DEAR SIR,—The following analyses made by Messrs. Howard & Sons of samples of bark taken in April last from seven of Capt. Cox's splendid ledgeriana trees may be of interest to some of your readers who purchased seed from me last season. As the analyses were sent by telegram I cannot give the decimal.

Class.	Crystallized Sulph. Quinine.
No. 1	...10·
,, 2	...12·
,, 3	...10·
,, 4	...10·
,, 5	...11·
,, 6	... 7·
,, 7	...12·

The field where these trees are growing contains exclusively ledgerianas, and is separated from the succirubra cultivation by a belt of jungle. Capt. Cox had previously had bark from most of the trees analysed, but I thought it best to have the remaining ones done, and I think you will agree with me, that the results are most encouraging.—Yours faithfully,

PERCY GUARD.

[Twelve per cent of sulphate, or nine of pure quinine is certainly a rich return: to compare with the analyses of Ceylon bark, we should like to have the age of Capt. Cox's trees.—ED.]

INSECTS IN CINCHONA NURSERIES AND COPPICING AT 6 OR 8 FEET HIGH.

Maskeliya, July 10th 1882.

DEAR SIR,—Can you or any of your numerous readers inform me through the medium of your journal what is the best thing to kill insects in a nursery seed bed? The insect destroying powder, sold in packets, is simply worse than useless. Would dilute tobacco juice or kerosene oil bo of any use and what percentage of each in solution would be innocuous to the young seedlings? As a "combination of spoke-shaving and coppicing", what do you think of topping cinchona (say at 2 or 3 years old) 6 or 8 feet from the ground, and allowing them to throw up two suckers from that height, one sucker to be cut down after 3 or 4 years' growth, when two more would be allowed to start and the 2nd suckers to be cut down after 7 or 8 year's growth: the 8 feet of stem to be permanent for the purpose of "stripping" or spoke-shaving yearly?—Yours truly, KNOSE.

[Phenyle is the latest remedy recommended, but we have not yet tried it. The process our correspondent suggests is really topping and we should doubt its success. There is nothing like trying, however.—ED.]

COFFEE WOOD FURNITURE.

"Imperial Cæsar dead and turned to clay
May stop a hole to keep the wind away."

Madulkele, July 10th.

DEAR SIR,—Chairs made of coffee wood by the Sinhalese carpenters of Matara used to fetch from five to ten rupees apiece in the local markets. The purchaser I am sure (though conscious of giving a high price which cannot rule very long) gives his money not for only possessing what is a curiosity, but for what is in fact a piece of handsome household furniture which combines beauty with durability. The wood, when polished, looks like ivory; and walking-sticks made of it are considered to be not only beautiful but strong. Having the possibility of developing a profitable industry in this useful manner, the reflection is revolting, why such nice coffee stumps or stems as those to be found in old estates now abandoned should be allowed to decay and be lost. Ceylon exports ebony and satinwood to England and the Continent, and I think it will not be difficult to send a trial shipment of coffee wood to the recipients of the former. It will be presumptuous on my part to dictate to you the manner how an export trade might be opened: be that what it may, the result will undoubtedly alter the present misfortunes of hundreds of proprietors whose once flourishing shrubs of coffee are now so many scenes of desolation —Yours obediently, A. VAN STARREX.

[We have recently seen pretty tables ornamented with rustic work made of coffee stems. We should think the close grain of coffee wood might render it valuable as a substitute for boxwood, which is getting scarce and dear. There are some big coffee trees in Ceylon, but they must hide their diminished heads in comparison with those to be seen in Java—perfect trees, a mass of ferns and rich orchids. Now as in the time of Sir Stamford Raffles, deals of a respectable size can be obtained from old coffee trees.—ED.]

SPORTING OF CINCHONA AND COFFEE.

Agrapatana, 15th July 1882.

DEAR SIR,—Your authority says cinchona and coffee belong to the same family, and it is not impossible that some of the sporting of cinchonas on estates might be due to the pollen of the coffee fertilizing the ovules of cinchona. Now, this granted, would be give us his opinion of what results might happen, should the pollen of the cinchona fertilize the ovules of the coffee tree, and also his opinion of the results of self fertilization on our *coffea arabica*.—I remain, dear sir, yours faithfully, J. D. W.

[In reply, all I can say is that nothing is known of such on the family to which coffee belongs, and further, unless actually done with camel-hair pencil it is but seldom we get a seedling from coffee to remain under the trees. It would be very interesting to know what would be the result.—A. C. D.]

A GOOD WORD FOR C. OFFICINALIS.

Agrapatana, July 15th, 1882.

DEAR SIR,—I am glad to see some one saying a good word for *officinalis*. As in the top end of Bogawantalawa so here many acres of fine healthy officinalis can be seen. For instance Preston, Stair, Waverley, St. Regulus, Thornley, Bromley, &c. Most of us know that in our hurry to be in time and our rush to get rich we have put out millions of weak cankered rubbish from our nurseries of immature seed from sickly trees, but that is no reason to damn *officinalis*, root and branch. There are of course many soils and positions unsuited to it, but give a good healthy plant a satisfactory chance in a suitable situation and it will prove a most valuable possession. I have some 20,000 trees from eight years old down to four years which have most of them survived three scrapings and show no tendency to die out. Also to perpetuate and continue our valuable hybrids we should plant *officinalis* with succirubra and others. When coffee was being planted far and wide, how many clearings were spoilt by bad plants being put in. But that did not damn coffee as coffee, so why should *officinalis* be damned, * a more delicate plant than coffee, because bad plants have been badly planted in bad situations.—Yours truly, R. W. W.

CEYLON TEA IN THE LONDON MARKET.

Strathellie, Nawalapitiya, 16th July 1882.

DEAR SIR,—It may interest some of your tea-growing readers to know that the 6 chests of tea referred to in your London correspondent's letter as selling at 8d per lb. contained what is commonly known as red leaf. A few months ago I sent 6 chests of the same quality, but the market was then stronger for teas of this rough descriptions and they sold at 10d per lb.

If our red leaf fetches such prices we may look for something very good for our fine teas when we have occasion to put them on the market. Demand has been so great privately that I have not for two years sold any tea in London, but intend shortly sending a break of 20,000 lb. to the Lane by way of testing the market. —Yours faithfully, P. R. SHAND.

ANALYSIS OF CINCHONA BARK: COMMERCIAL AND SCIENTIFIC.

Colombo, 27th July 1882.

DEAR SIR,—Referring to your note to the letter of "Enquirer" in the *Observer* of the 26th instant, drawing a distinction between a "scientific" and a "buyer's" analysis of cinchona bark, I note that you characterize the latter as a "rough and ready process" in comparison with the former. If, by a "buyer's" analysis, you mean certain tests which buyers may apply to the bark for their own satisfaction, this may be true; but if you really mean a "commercial" analysis, or one that is meant to satisfy both buyer and seller,

* The synonymous word "condemned" has a more pleasant sound!—ED.

I have no hesitation in saying that no "rough and ready process" will do. A "commercial" analysis has no doubt a different end in view from a purely scientific analysis, viz., to ascertain how much of the alkaloids, and specially of quinine, can be separated in a pure crystalline marketable form; but the care and skill required to do this are quite equal to, and if extended to the inferior alkaloids, perhaps greater than are required to tell the exact proportions of the four alkaloids usually found in cinchona barks.

M. COCHRAN.

[What then is understood in the "bark" trade to be the difference between a "buyer's" and "seller's" analysis?—ED.]

SHADE TREES FOR COFFEE.

17th July 1882.

DEAR SIR,—In your July number two correspondents writing from Coorg and Mysore take exception to my abuse of jaks as shade trees. Will you allow me space for a few observations on their remarks. "L. I. P." acknowledges that this tree is only now undergoing probation in Coorg, so that his favourable conclusions may be considered premature. It is quite within the possibilities that "after the lapse of a few months" jaks will be looked upon as "very much the reverse of A 1" as shade trees. Ceylon experience of the last few weeks has shown that this is anything but a land of "languid air," so that, if we follow "L. I. P." 's advice of keeping our trees well trimmed, we shall be casting away their chiefest use, to wit their screen power.

My objection to the litter caused by the ever dropping leaves is based solely on my experience of drains choked from this cause and the effects beyond this choking. I could show "L. I. P." surface-feeding jak roots 20 feet long and more, and I have no hesitation in saying that, where jaks are planted among coffee in land having a substratum of rock, the former will thrive and the coffee die out.

As a rule, jaks of a certain age do look healthy; still that argues nothing for their kindness to the coffee, for the benefit of which these trees have so long been planted in Ceylon to no purpose.

Such was (and is) my *unbelief* in these trees that I took steps a few weeks back, which have ensured the possibility of seeing, not a, but many a, "blighted jak"! "L. I. P." may be interested to hear that in Ceylon we seldom make nurseries, but sow jak seed at stake in the wet months.

As a *shade* tree I pin my faith on a less melancholy object than jak, viz. the tree known to the Tamils as *murungay maram*, and well-known for its scarlet blooms and bean-pod-like seed-cases. Perhaps you will give us the botanical name of this tree. [The botanical name is *moringa pterygosperma*.—ED.]

"Masheer" is right: I have never had the opportunity of seeing Mysore with its gardens "where they grow the coffee berries"; would that I had! It is no marvel to me that "Masheer" has for so many years obtained satisfactory results from his sub-jak coffee property *(esto perpetua!)*: the climatic conditions of Mysore and Ceylon being so dissimilar.

That *shade* is no protection from *the* fungus in this country is open to doubt; but that shade which is light, and is likewise *shelter*, is a power for good against hemileia, no one can deny. "Masheer's" experience in Mysore, and Mr. W. D. Bosanquet's grand results on Yoxford in this island, ought to revive the drooping spirits of those present objects of pity, the proprietors of coffee estates.

Supplying here has generally been found to be merely waste of money, when our old island stock plants have been used. According to "Mahseer" we have only to introduce the Coorg and Nalknaad varieties among our coffee to stave off, as he stayed off, that "absolute ruin," which, without some such provident step, is most certainly imminent.

The alternate path, and to my mind the safer of the two, is that so pluckily and faithfully trodden by W. D. B., viz, cultivation based on scientific principles. *Vive la science! A bas* injudicious manuring and pruning!

If W. D. B. can make his trees, young and old, bear fruit, *in spite of leaf-disease*, so as to approximate an average, year after year, of 6 cwt. all round, when most estates are doubtful of securing and many dare not calculate on a box per acre even, surely we have a safe pilot in him.

It will be our fault now if we fail to bring the old enterprize round to the condition it was in five years ago only, and to better fettle than that; but we must be as plucky as our leader, and, above all things, *avoid half-measures*. If an analyst is deemed necessary to each estate, or group of estates, we must not hesitate to employ an analyst. Time will allow of no dilly-dalling. 'T is a case of now or never. The restoration of all our younger estates is no longer theoretical. *W. D. B. has proved its practicability.* To each proprietor who can afford—ah, there 's the rub—to work on the lines laid down by the manager of Yoxford, I would in all good faith say:—

Respice finem.
"'T will soon be dark.
Up! mind thine own aim, and
God speed the mark."

Faithfully yours, P. T. L.

[Our correspondent will be understood as being "kinder sarcastic" in regard to Mr. Bosanquet's experiments. But we suppose it is simply the impossibility of the necessary funds being obtained, which staggers him. Perhaps Mr. Bosanquet will now state, in addition to rate per acre of coffee obtained by his system, the cost of culture and resulting profit.—ED.]

HAY-DRYING FANS AND CINCHONA DRYING.

Lindula, 19th July 1882.

DEAR SIR,—I should like to draw your attention to the following paragraph in the latest *Freeman*, in case you have not noticed it:—"Some interesting experiments have been conducted at Solna, Roehampton, under the auspices of Mr. Allender, with one of the new Neilson fans for drying hay in wet weather." We have had such terrible continued wet weather here lately that it has been almost impossible, even in a tea store with fires going, to keep our cinchona bark from getting mouldy, and if you could procure further information as to the process and success of these drying fans, we planters might find them a safe investment.—Yours faithfully,

KAROLY FÜRDÖ.

THE BARKING AND SHADING OF CINCHONA TREES.

SIR,—A great deal has of late been written about the barking and shading of cinchona trees. I trust the few practical notes on the different materials I am now about to enumerate may come of some assistance to my brother planters. There is such an extensive field before us, of valuable trees, plants, grasses and mosses, and so many within the reach of almost every cinchona grower, I only give those generally know and that can be found in almost every district. All material should be well dryed before use and the seeds thrashed out off the grasses. A coolie with a good clean stick will finish a large quantity in a day.

Ferns.—Pteris aquilina: the bracken," found all over the world and known by every planter. It is found

in all the old districts and several of the new. Very easily collected and makes an excellent covering.

Pteris biaurita : this is the most abundant fern in Ceylon, and is found from the sea coast to the highest mountain top. Those having nurseries should know this fern well and the great value it is for shading young plants. To the planter it is of great value in many a way.

Pteris quadriaurita : this variety is generally found growing with the former.

Mosses.—Hypnum : there are a great many varieties of this moss to be found in the jungles, and all are useful for covering, and often used.

Sphagnum : varieties of this moss are found in marshy places and often two feet long. It is much used in England for decorating and packing

Lycopodum cernuum, stagsborn moss, badal wanassa of the Sinhalese : this moss is well known for its great beauty and value for decorating churches and ballrooms.

Lycopodium clavatum, common club moss, badge of the Sinclairs : common at high elevations, much used in Scotland for decorating. The seed spores are of a strong repulsive power and also highly inflammable.

Grasses.—Paspalum scrobiculatum, ammu, Sinh. : common grass all over the island and eaten by cattle.

Panicum sanguinale : very abundant and one of our common pasture grasses. Cattle are very fond of it.

Panicum repens, attora, Sinh : very common, much valued by the Sinhalese as cattle fodder, but trouble some weed on some coffee estates. This is one of the common grasses sold in Colombo.

Panicum jumentorum, guinea grass : this grass is well known and when dry makes an excellent covering.

Panicum barbinode, Mauritius grass : even this grass in a dried state will be found useful for a covering.

Garnotia stricta : good thatching grass, resembling iluk, and found at high elevations.

Spodiopogon obliquivalvis, rat-tana, Sinh : common all over the island and extensively sold in Colombo as fodder for horses.

Anthisteria ciliata, kangaroo grass : this is one of the most abundant and most valuable of our patana grasses, and when cut and dried is splendid fodder for cattle. Abundant in the patanas of Uva, Dimbula and Kotmale. It is extensively used for covering cinchona trees on the Uva side, and I have seen it used in Dimbula. The worthy Laird of Mattakelle used to cut this grass for cattle fodder some years ago, and his fine hay-ricks have been commended by many.

Andropogon Martini, mana grass : this grass is well known and requires few remarks on its use.

Andropogon venustus : resembling mana grass and found at high elevations.

Andropogon pertusus : abundant in the warmer parts of the island and valuable fodder grass in green or dry state.

Pollinia tristachya : found growing in wet peaty parts on the patanas at high elevations.

Imperata arundinacea, iluk, Sinh. : excellent thatch grass and found all over the island, generally in stiff ground. Troublesome weed on some coffee estates and difficult to root out.

Oryza sativa, rice plant : the indigenous variety. Of varieties in cultivation over India and Ceylon, there are about 200. Paddy straw is well known, and its great value as fodder. In some of of the old distracts it can be got very cheap and is one of the best covering for cinchona trees.

Musa sapientum, plantain : the dried leaves and stems of this plant are of great value for tying material, and also suitable for covering purposes.

Cocos nucifera, coconut palm : the most valuable commercial tree in the world. The plaited leaves known as cadjans are valuable as a roof covering for houses &c. In covering cinchona trees the work can be done very neatly and last for a long time. I consider grass material by far the best covering that can be used : it is certainly superior to sacking or any other manufactured article.

Its open nature enables the air to pass through freely, thereby creating a more active life in removing the bark.

No species of tree requires a thick cohesive covering. All we want is a simple shade from the direct rays of the sun.

In districts where troubled with "white ants," to prevent them from ascending the trees, do not remove he bark within a foot from the ground.—Yours,

OLD BOTANIC BOY.

CINCHONA BARK ANALYSES.

July 19th, 1882.

DEAR SIR,—I should have written ere this to acknowledge and thank you for the full and complete information afforded in your issue of 11th inst., upon the question of the analysis of cinchona bark, in answer, I presume, to a letter of mine of a former date. Needless to say the question was suggested by a note of your own as to the desirability of district medical officers taking up the work of assaying cinchona bark, but a reference to the process as shewn in the article alluded to would show how extremely difficult it would be to carry out the details, in addition to one's own proper work in the district. In the works previously alluded to by you there are simpler, but perhaps not so accurate, methods alluded to—one of which I have tried—but you have also shown how extremely difficult it is to get reliable analyses, and I question very much whether one from upcountry would, even in time, be relied upon ; and until we know what is to be our position under the proposed alterations as to medical aid in coffee districts, one would be rash to incur much expenditure upon the matter.—Yours faithfully, ENQUIRER.

[We learn that there is a good deal of difference berween a buyer's analysis for manufacturing purpose and an analysis for scientific purposes. The latte shews the contents with almost mathematical accuracy : the former is a much more rough-and-ready process. There can be no great difficulty to overcome, seeing how quickly the art has already been picked up by Ceylon men.—ED.]

ON BEES IN THE PLANTING DISTRICTS.

[VERY INTERESTING.—ED.]

SIR,—Some one was writing a few months back that all bees had deserted the Dimbula district, but it has been quite the other way within Uva, swarms of bambara having been passing continually seemingly from east to west.

The reason of there being so many this year is that the nilu, a nice smelling blue flower* that contains much honey, has been out in full bloom. The Sinhalese say it only comes out once in six years; however that may be the bees always seem to turn up with it, this being their favourite food, a proof of which is that the taste of the honey and scent of the nilu is much the same. Seeing so many swarms about I thought to secure some, so had a frame hive made after the English pattern with sliding frames, glass top &c., and finding a large swarm in the coffee under a low rock I took my appu with me at night and secured the lot in a pair of pyjamas in this way :—First tie up the legs of this article of apparel, then gently put the top part over the bees close up against the rock, then

* Strobilanthus.—ED.

with a stick cut away the bees as they hang and they all fall down in a mass, when by pulling the tape of the pyjamas the top is closed and there you have them a buzzing seething hot mass of life. Having reached the bungalow they were let out of captivity into the hive by one of the legs, when they all settled in a mass on one of the frames.

The bambara are very handsome, with a golden body, and are much larger than the British bee. But it seems impossible to domesticate them: they object to a box, strongly preferring to hang from a big rock, generally a cliff under a light shade of hanging vegetation or from the branch of a big tree.* At least I found it so with the five different swarms I took. Some I kept quiet for a week, feeding them with honey, which they always ate too much of, making themselves very drunk, from the effects of which most of them died. Others were fed in the same manner that English bees are fed in winter, but with no other result than that whilst the dull weather lasted they would fly in and out of the hive as if they meant to remain, but with the first bright sunny day they one and all cleared out in about five minutes.

Failing to get honey by domestication I set to work to procure it from the cliffs: an easy matter when you know how. It is done in this way:—Collect a small bundle of dried sticks and bind these together with jungle creeper and then surround the bundle with small green branches; set fire to the sticks; when the branches give out a dense smoke wave this under the bees; when they fly away from the smoke this movement should be hastened with the hand by brushing off those that are lazy, and when they are all gone cut away the comb with a knife and make "tracks." It is as well to have some one at hand to help when the knife is wanted, and to hold a dish or pail for the honey when taken. The bees buzz around the smoke but won't come within it.

The larger the swarm, the bigger the comb. The average comb is about 1 foot to 1½ foot broad × 1½ foot to 2 feet deep, hanging down in a half-moon shape. At the top, where the comb fixes on to the support, the cells are as deep as a Bryant & May match is long, and full of very tasty honey. The honey cells occupy the top part of comb for about a space of 6 to 8 inches, the cells gradually tapering down from the above dimensions to the smaller size of ¼ an inch, when they reach the honey limit of 8 inches: then the cells for the young bees appear to the length of another 10 inches. There being 16 cells to the square inch, and two rows of cells each side of the midrib of a comb, I calculate that there would be about 6,000 young bees within, and about the same number of old ones without.

In all the combs that were taken no queen bee's cell was found, and I have never seen a bambara queen bee amongst the swarms that were taken, although I have found three and four queen bee cells in one comb of the *apis indica*. Can it be that the bambara have no queen bee?

The Sinhalese have an idea that bambara bees gather the honey when there is no moon at night, and eat it at the period of the month when the moon is full. This idea must have been taken from Dr. Watts' rhyme:—"How doth" &c.!

The nilu being finished there was not a bambara to be found: they all flew away to the north or north-east, but to where could it be, to India? Many Sinhalese keep *apis indica* in chatties over their huts. They are also found inside hollow trees and clefts of rocks but they are a very mild bee compared with the bambara, that can be fierce at times. † A story is told that a planter was chased through a new clearing by a swarm and only escaped by going to bed and pulling down the mosquito curtain. The wax is of a beautiful whiteness,—Yours, HONEYDEW.

* In India their habits are the same.—ED.

† As poor Mr. Benton found to his cost: by-the-bye has "Honeydew" read Mr. Benton's letters on this subject in our columns?—ED.

NUTMEGS.

DEAR SIR,—Any one experienced in the cultivation of nutmegs will, I daresay, be able to explain the reason why some trees only blossom and do not set at all. I have twenty-six trees, all but ten bearing: the latter blossom magnificently and never set.

They are somewhat closely planted, or rather the spreading branches touch each other and I believe they are about 10 feet apart, and I would be thankful to any one who will let me know if by any artificial means these ten trees could be made to bear.—Yours faithfully, MALIGAKANDA.

THE CORK TREE.

DEAR SIR,—The cork oak grows readily enough as low as 800 feet above the sea in some parts of Portugal. The bark is taken about once in 11 years. If you cut any cork longitudinally you can see certain cross marks or divisions, each division represents the growth of a year. No trouble is taken in the cultivation and the cost of nurseries is trifling. I should think that the climate up-country generally, would be too wet for the cork oak, but of course that can be only seen from experience.—Yours truly.

R. I. P.

CINCHONA OFFICINALIS: THE OTHER SIDE OF THE PICTURE.

Bogawantalawa, 20th July 1882.

DEAR SIR,—I am sorry I cannot agree with "Hybrid" in your issue of 18th, if he implies that officinalis cinchona has found its zone throughout this district.

In my humble opinion a large sum of money has been sacrificed in convincing us that officinalis is too uncertain to warrant its cultivation here, and I regret having been misled by the promising appearance of plants one and two years old. It is possible that Loinorn and the estates adjoining enjoy exceptional soil and climate but with the experience I have had, I fail to see why we should not stick to succirubra and hybrid, the growth, analysis and certainty of which place them in advance of any other variety we have tried.

The existence of a fine old officinalis tree, here and there, or even of a group of trees, is anything but conclusive evidence in favour of "Hybrid"'s opinion Let him enquire what percentage of officinalis plants *carefully put out* has failed in Bogawantalawa and Dikoya, since 1869, and I think he will change his opinion.—Yours truly, V. A.

THE TEA ENTERPRIZE IN CEYLON: 5 YEARS' OLD TEA YIELDING OVER 6 MAUNDS PER ACRE IN AMBAGAMUWA.

Colombo, 22nd July 1882.

DEAR SIR,—In your issue of the 8th instant wherein reference is made to the tea on Galkebedde estate, it is stated that the estimate for coming year is 5¾ maunds per acre; probably your correspondent has mixed up the coming season with results already obtained, and we therefore append a memorandum of the yield from the beginning, which should afford encouragement to all engaged in the enterprize. For the coming season we hope to again exceed 6 maunds per acre.—Yours faithfully, MACKWOOD & CO.

Planted June to August 1877.	per acre.
Yield for 12 months ending 30th June 1880 =	98 lb.
,, ,, 30th June 1881 =	392 lb.
,, ,, 30th June 1882 =	530 lb.

C. OFFICINALIS.

Udapusselawa, 22nd July.

DEAR SIR,—In your issue of the 18th instant appears a letter about a successful clearing of C. officinalis in Bogawantalawa. Any one not well acquainted with the facts concerning C. officinalis would think this letter and statement rather startling, considering how much this variety of cinchona has been run down these last twelve months or so past, by many who have not been successful with it. But any one who would like to see C. officinalis growing to great perfection need not go many miles out of Nuwara Eliya towards Kandapola and Upper Udapussellawa, when they will see some splendid fields of this variety of cinchona at all ages from one to five years old If I am not out of place, I will mention three or four estates in which C. officinalis is growing most luxuriously in Kandapola and Tullibody, there are fields of beautiful trees three to five years old, and also on The Park and part of Eskdale adjoining the Park there are some very fine fields, looking very healthy and strong, between three and four years old. Altogether between these last-mentioned estates I should think there were 150 to 180 acres of this age, and so far it is a pretty sight. Part of Kenmare has some fine cinchona, but it is rather mixed. There is also a fine field of C. officinalis in Dovedale, at Kandapola Gap. Hillside, Concordia and Brookside can show some fine C. officinalis, and also other estates in this neighbourhood, the names of which I cannot recollect just now. But the fact is so little is said about this beautiful part of Ceylon, that very few know how successful some have been with this variety of cinchona, and I feel certain there is yet a bright future for both cinchona and tea at Kandapolla.—Yours faithfully, C. OFFICINALIS.

NATIVE BUYERS OF CINCHONA BARK IN THE PLANTING DISTRICTS: A CAUTION.

Maskeliya Valley, 26th July 1882.

SIR,—The Order of the Bath is to be obtained gratis up here. Tea and cinchona planting are all the go, as you are well aware. Tea planting at stake appears to be the thing. But planters must keep their "weather eye" open. An "oriental" is knocking about "offering to purchase cinchona bark at 25 cents per pound," and what's more the coolies on an adjoining estate are well aware of the fact. If all planters refused to sell their bark to such fellows, pending robbery might be thwarted; but, if they once come to terms with a planter, the bark bought would be held up as an exense, while pounds of bark at 25 cents might be made away with by estate coolies. Action is wanted and joint action too, or "look out for squalls."—Yours truly, ALPHA.

SOLUBLE PHENYLE AND INSECTS.

(To the Editor, "Madras Times.")

15th July.

SIR,—In reply to a "Bellary Boy's" appeal, which appeared in your issue of the 14th inst., I would strongly advise him to procure a bottle of *Little's Soluble Phenyle* from Messrs. Norton & Co., of the Mount Road, Madras. A small quantity of this liquid, diluted with water in the proportion of 1 in 50, and sprinkled near the places which black ants and cockroaches usually frequent, will disperse them in a few minutes. FACT.

No. II.

Young Rotshchild, July 24th 1882.

DEAR SIR,—In your issue of 22nd I see a correspondent "Knose," asks "What is the best thing to kill insects in a nursery bed?" Speaking from actual experience, as far as cinchona is concerned, the *best* insecticide is the Phenyle you mentioned in your foot-note to his letter. This preparation is in the form of a highly concentrated liquid, and requires diluting with water only. I refrain from saying more, not wishing to make your correspondence columns the medium of advertizing an article for which I am the agent, but if "Knose" will communicate with me direct, I shall be very glad to give him or any one else the fullest particulars.—Yours faithfully.

JOHN N. GRANT.

CINCHONA.

[To the Editor, "Australasian."]

SIR,—I shall be greatly obliged if you can afford me the following information:—1.—What portion of Northern Australia is best adapted to the growing of cinchona? 2.—How much capital is required per acre 3.—How long before one gets any return? 4.—What is the average yield of bark per acre?

Melbourne. CINCHONA.

[The best parts of the Northern Territory would be the sheltered slopes of the higher lands, where the soils are good and the rainfall regular. Mean temperature, about 60 deg. or 65 deg. One acre of land, in South India—Clearing, 10r.; planting, 20r.; maintenanee (as replacing plants that have died, weeding, &c.) per acre, per annum, 70r. 4,800 trees planted on one aere; at the fourth year thin out to 2,400 trees, which would yield about 1,200lb of bark, value 1r. per lb. 1,200r.; at sixth year thin out to 1,200 trees—yield, 1,200lb bark, at 1r. per lb., 1,200r.; eighth year, 1,200 trees will yield 2lb bark, at 1r, per lb. 2,400r. Total, 4,800r. Summary—Expenses: First year, 100r.; second, third, fourth, fifth, sixth, and eight year, 420r. Total, 520r. Results (eight years bark as above): 4,800lb bark, 4,800r. Gross profit for eight years, 4,280r. Reckoning the rupee at two shillings this would be £428.—*Australasian.* [A too-too satisfactory estimate: no doubt inspired by Mr. H. Poett. —ED.]

INDIARUBBER PLANTS.—Mr. W. T. Thiselton Dyer, C.M.G., laid before the Linnean Society on June 15 an important communication "On the Caoutchouc-yielding Apocynaceæ of Malaya and Tropical Africa." After giving a general sketch of the structure and physiological conditions of the occurrence of caoutchouc in plants, the author pointed out that the plants which appeared to yield it in commercial quantity in three widely separated regions, all belonged to one tribe of Apocynaceæ—the Carisseæ. In the East Indies, the Gutta Singgarib of the Malay Peninsula, the Gutta Soosoo of Borneo, was the produce of a new species of Willughbeia, W. Burbidgei. Many other species of this and other allied genera also seemed to produce caoutchouc in quantity worth collecting. In Central Africa, Landolphia, which was closely allied to Willughbeia, but differed in possessing terminal instead of auxiliary flowers, was the most important source. On the East Coast caoutchouc was yielded by L. owariensis and L. florida, the latter a very ornamental plant. As the rubber exuded from the cut stems it was plastered on the breast and arms, and the thick layer, when peeled off and cut into squares, was called "Thimble rubber." On the West Coast the most important species was L. Kirkii, the rubber of which could be wound off into balls or small rolls from the cut stems like silk from a cocoon; this species was called "Matere." L. florida also occurred, and was called "M'bungu;" its rubber was worked up into balls, but was inferior in value. The rubber of L. Petersiana was of little importance. In South America, Hancornia speciosa yielded what was called "Mangabeira" rubber.—*Gardeners' Chronicle.*

SLAVERY.—Our West Indian sugarplanters will hear with interest that a strong effort is being made in Madrid to secure the entire abolition of slavery in Cuba. At a largely-attended meeting of the Abolitionist Society held during the week demand was made for the abrogation of the law under which no slaves are to be liberated till 1886, and which compels all slaves to forced labour under their then masters for two years after that date. A painful sensation was produced when the speakers illustrated the present condition of the 200,000 negroes in Cuba by pointing to a whip, iron chain and heavy iron collar, and other instruments of corporal punishment still used under the so-called Emancipation Law of 1880, which really authorizes the sale and barter of human beings until 1888. A member of Congress who has recently visited Cuba declared that 60,000 negroes were kept in slavery by their owners eluding the laws concerning African-born slaves. It is expected that the abolition of slavery will be proposed in the Cortes by the Cuban members. This fact suggests the reflection that in one respect at least the Spanish Colony is more advanced than our own Colonial possessions—it has direct representation in the central Legislature.—*Colonies and India.*

FRUIT-GROWING IN JAMAICA.—Just as the raveags of *Hemileia vastatrix* have induced the planters of Ceylon to turn their attention, with great advantage to themselves, to the culture of chinchona, tea, cocoa, and other produce, instead of pinning their faith to coffee alone, so the sugar-growers of Jamaica have learnt by adversity the impolicy of devoting their whole capital and energies to the production of the single article sugar. Encouraged by the success of the experiments which have been made by the energetic Director of the Botanical Gardens at Kingston, they have turned their attention with great success to the introduction of chinchona, while cocoa, vanilla, and other indigenous plants, which have not hitherto been thought of such importance as to demand serious efforts to secure an extensive produce and sale are being taken in hand. In fruits of various kinds, says the *Colonies and India*, perhaps the greatest success has been attained so far, and instead of merely collecting enough to supply local wants, and remaining content with an occasional shipment to New Orleans, of fruit, which possibly, owing to bad packing, went bad before it reached its destination, Jamaica planters are developing a remunerative trade in oranges, bananas, pine-apples limes, shaddocks, mangoes, and other fruits. Even grapes are being grown for export. The United States are at present the chief market for their produce, but England receives no small share of the yield, and still larger quantities of fruit in even greater variety will no doubt be shipped to Europe, as experience shows that better means of packing can be employed to avoid the deteriorating effects of a long voyage. The export of oranges to the United States from Jamaica has increased 50 per cent. in the last six years; of bananas it is expected that the export this year will reach two million bunches, or twenty times as many as in 1876. When it is remembered that each "bunch" contains 250 pods, the extent of the trade may be realized. Fifteen million coconuts, or double the quantity exported last year, will, it is anticipated, be sent out of the island before the end of the present season. Oranges are one of the principal items in the fruit trade, and as the Jamaica variety has a peculiar property of keeping good for a longer period, even when fully ripe, than the European variety, the advantage which the island has in the growth of this fruit is very great. These instances will show the advance that is being made by Jamaica in this direction, and the possibility that lie before planters in the future. To small capitalists of a horticultural rather than agricultural taste Jamaica offers, in her delicious climate, her fertile soil, and the abundance and variety of her produce, exceptional advantages. Small areas of land can be had on very reasonable terms, and few colonies present better opportunities to gentlemen of small means who would turn to profitable account that love of "gardening" which is innate in most Englishmen. Fruit culture in Jamaica demands little of the hard labour of wheat farming, while it yields results, perhaps, even more profitable.—*Globe.*

COFFEE MIXTURES.—We last month quoted a clause from the Customs and Inland Revenue Bill now before Parliament, which, it appeared, would absolutely prevent the sale of any mixture (except chicory) with coffee. We thought it rather hard that if any person should really desire to have a combination of coffee and dandelion he should be prevented by law from purchasing such, and we wrote to the Chancellor of the Exchequer to ask if such a mixture would be allowed to be sold provided the proportions of the ingredients were definitely stated. The following reply indicates that dandelion, or taraxacum, coffee will be allowed to be sold as heretofore:—Inland Revenue, Somerset House, May 25th, 1882. SIR,—The Chancellor of the Exchequer having forwarded to this department your letter of the 2nd instant, I am instructed by the Board to acquaint you, in reply, that dandelion root will, it is understood, be considered as analogous to chicory; and, provided duty be paid accordingly as for chicory, no objection will be raised to the sale of a mixure of dandelion root and coffee. —I am, &c. (Signed) CHAS. B. FORSEY, Secretary.—The Editor of the *Chemist and Druggist.*

"SMUT" DISEASE IN CANE.—A committee, consisting of the following gentlemen, having been appointed by the Victoria (Natal) Planters' Association to enquire into and report upon this disease—C. T. Saner, W. R. Cowley, A. Dubois, and Leonard Acutt—made the following report:—Your Committee recommends the Association to take immediate steps to promote the introduction of new varieties of cane from different countries. In the meantime it recommends that the following means be adopted to prevent the deterioration of the different varieties of sugarcane the country already possesses:—1. Better cultivation generally; 2. Care in selection of plants, planting only from our most vigorous canes; 3. Obtain plants from other estates and districts; 4. Establish nurseries in which plant canes obtained from a distance; manure such nurseries with natural manure only, as a forced plant is apt to be as weak as neglected canes; 5. From indifferent soils, take off only a plant crop and one ratoon crop, and from good soils only plant crop and two ratoon crops. There will then be no bad cane in the country to be used for plants, or to contract and spread diseases; 6. Root the canes out completely from abandoned or fallowed fields, as diseases are always rife in canes which are allowed to grow up among grass and weeds, and the land does not get a complete rest; 7. Adopt the Mauritius plan of planting other crops in fallow fields: it is better for the land than allowing it to revert to weeds and grass. A suggestion made by a member of Committee may recommend itself to some planters. To establish nurseries off the coast in places where frost is rare, it is thought that a cane grown in a more temperate climate will prove hardy when propagated on the coast. In conclusion your Committee records its opinion that the disease will cause great loss, unless vigorous general action is taken for its eradication. But that, having in view the satisfactory results following attempts to cope with it, added to the fact that it has been known and dealt with in Mauritius for so many years, it sees no cause for alarm, if planters are alive to the danger and are determined to stamp it out.—*Natal Mercury.*

TEA cultivation in the Andaman islands is a great success. On the 14 acres of tea which were under cultivation last season the out-turn has been 411 lb. to the acre, for the twelve months. Forty-seven acres more land have lately been planted out, and a further extension up to 200 acres is contemplated.—*Madras Mail.*

CINCHONA.—To the planters of cinchona who have suffered so severely from the recent gales and floods, from the number of trees blown down, and the heavy wash of surface soil, the figures we gather from the trade returns will be some comfort. While the quantity of cinchona bark exported from India has greatly decreased in 1882, the quantity of quinine imported has enormously increased. Thus :—

Cinchona Exported.			*Quinine Imported.*	
	lb.	R.	lb.	R.
1880...	4,85,484	6,87,526	1879... 5,940	6,50,005
1881...	6,99,258	7,24,705	1880... 7,409	8,60,072
1882...	4,28,497	4,58,340	1881... 3,964	4,29,515
			1882... 10,65	9,98,631

The falling off in the exports of cinchona bark cannot be accounted for by want of confidence in the undertaking on the part of cinchona planters, for a number of new estates have recently been opened, and many plantations have been much extended. It would appear to be due in a great measure to the large quantity of bark retained in the north, for the purpose of making the new febrifuge, and to the smaller quantity of bark taken from the Government plantations on the Neilgiris. The price of quinine having been much lower in 1882 may have induced larger imports; and the stock on hand from the previous year, during which the imports were comparatively small, may have necessitated the greater demand for present and future consumption.—*M. Mail.*

ON THE USELESSNESS OF SOME OF OUR ORDINARY DISINFECTANTS.—In an official volume just published by Dr. R. Struck, Chief of the Sanitary Department of Germany, Dr. R. Koch has published the results of his studies upon disinfectants. He used, in order to test the value of a disinfectant, the micro-organisms of splenic fever which exist in the form of minute, round spores or micrococci, afterward developing under favorable conditions into slightly larger, rod-shaped bodies or bacilli. It was found, though this indeed was already known, that the spores had a much greater vital resistance than the bacilli. Two per cent. solutions of carbolic acid, after three days' contact, only hindered the development of the spores, but even five per cent. solutions did not kill them. On the other hand, one per cent. solutions killed the bacilli within a few minutes. Furthermore, one part of carbolic acid in 1,000 parts of beef broth prevented the further development of bacilli. These are important facts, since they show a source of error in former experiments. It has been stated by Endemann, Sternberger, and others that carbolic acid solutions of about two per cent. strength destroy the activity of low organism. But this, if Koch's experiments are correct, evidently cannot apply to all organisms, or to every life-form of the same organism. Koch tested the power of sulphuric acid, chloride of zinc, borax, white vitriol, and other substances. He found them absolutely incapable, in any ordinary solution, of killing the spores. Such substances as arsenic, quinine, and perchloride of iron would, in one or two per cent. solution, kill the organisms in the course of six or ten days, but were, on the whole, quite feeble disinfectants. On the other hand, a few substances only were found to be very active. Thus, two per cent. solutions of bromine, iodine, and chlorine, and of corrosive sublimate (the last being the best) killed the spores within a day. The power of these latter substances to prevent the activity and development of the bacilli was found to be very remarkable. Thus, one part of sublimate in 500,000 of water would completely check the activity of the organisms. Certain volatile oils, such as thymol and terebinthene, were also efficient in dilutions of 1 to 80,000 and 1 to 70,000. As the result of his experiments Koch came to the conclusion that only bromine, chlorine, iodine sublimate, and few oils of the class referred to were of value as disinfecting agents.—*Medical Record.*

ANSELL'S TEA SIFTER.—We hear this machine is thought more and more highly of. One correspondent, writing from the Dooars, says :—"Ansell's Tea Sifter is *par excellence* THE Tea Sifter of Tea Sifters. I have seen several tea sifters working, but none can hold a candle to Ansell's.—*Indian Tea Gazette.*

UPPER ASSAM, 2nd July.—We are getting a fair amount of rain just now, and there seems every prospect of a good season. In some gardens it has been found necessary to stop all cultivation, for the time, to take advantage of the heavy flush appearing there, while on other estates there has been almost a dearth of leaf. A great deal of new machinery has been called into use this year,—a pretty good sign, we think, that last year's workings were fairly profitable.—*Indian Tea Gazette.*

INDIAN TEA.—Practice and experience in drying and packing have taught the growers how to avoid the faults which at first detracted from the value of their produce, and in consequence Indian tea is becoming more appreciated by English consumers. The imports have reached the value of three millions a year, and are growing rapidly and steadily. The first consignment of the season of Darjeeling tea, which has just been sold, fetched the very fair average price of 1s. 6d. per lb.—a far higher figure than the most sanguine Indian tea-planters ever expected their produce to realise. One great advantage possessed by the Indian over the Chinese tea-grower is that Assam teas can be placed in the London market when the China teas are only just leaving Woosung or Shanghai.—*Public Opinion.*

TEST FOR GOLD.—I have asked permission of Mr. Haly for you to publish the enclosed.—*Cor.*

Colombo Museum, 15th July 1882.—Small parts are chipped from all the sides of a mass of rock, amounting in all to about a quarter of an ounce. This is finely powdered in a steel mortar and well mixed. About half of it is placed in a capacious test tube, and then partly filled with a solution made by dissolving twenty grains of iodine and thirty grains of iodide of potassium in about an ounce and a half of water. The mixture thus formed is thoroughly agitated by shaking and warming, and then, after all particles have subsided, dip a piece of pure white filter paper in it, allow it to remain for a moment, then let it drain, and dry it over the spirit lamp. It is then placed upon a piece of platina foil held in a pincers and this heated to redness over the flame, the paper is speedily consumed; and after heating further to burn off carbon, it is allowed to cool and then examined. If at all purple gold is present in the ore, and the relative amount approximately deduced, as much, fair, little or none. This method takes but little, time and is very trustworthy.—(Signed) A. HALY, Director, Colombo Museum.

MR. STORCK'S CURE FOR LEAF DISEASE.—A correspondent from Fiji writes to the Calcutta *Englishman* on Mr. Storck's cure as follows:—"Perhaps a word in conclusion as to a recent discovery of a cure for *Hemileia vastatrix* may not be uninteresting. I have seen the remedy in operation here, and from what I have seen I believe it to be a genuine thing. The inventor, Mr. Jacob Storck, has already been in communication with the *Tropical Agriculturist* in the matter, and it is probable he will proceed to Ceylon in October to demonstrate the value of his invention. His plantation, together with many others, was destroyed by the Government, on the appearance of *Hemileia* two years ago, no recompense being made save in one case, where Mr. Fillingham Parr recently got a verdict of £2,000 damages. Mr. Storck, being victimised, set promptly to work to devise a cure, and, after 12 months' continuous experimentalizing succeeded, at any rate to his own satisfaction, as not a plant now growing on his estates is infected. I saw the cure at work on a partially infected tree, which he assured me was at one time shewing the disease in its worst type. The cure is by vaporization, and the cost is stated at £2 per acre for purifying a plantation."

BUDDING CINCHONA.—We call attention to the planting paragraph from Maskeliya (page 249) wherein a planter of experience relates his success in "budding" cinchonas. He has several "buds" coming on well and is confident that by the use of two punches—the larger one for the piece of ledgeriana or hybrid that is to be "planted" into the succirubra and the smaller for the hole in the bark—this process will be found much simpler and more successful than grafting. In our forcing climate there is no doubt of the facilities presented for budding or grafting and we are only at the beginning of the improved processes which will be devised by Ceylon planters in cultivating and preparing) new products.

ANOTHER NEW AND PROFITABLE PRODUCT.—Mr. J. Holloway, of Wattegama, whatever may be thought of his faith in Coffea Arabica "properly treated," deserves on all sides credit for his indefatigable zeal over new products. A letter lies before us addressed to his Colombo Agents, in which he says :—

"I have sent to your address this day a box containing 4 lb. croton seed. Will you be good enough to send part to the Boston Exhibition (as Maria Estate Ceylon Croton Seed) and test the London or foreign market with the balance. I saw it quoted at 70s per cwt. in an English price current. Taking 10 lb. a tree as an average production it will pay well : my two large trees will give me 20 lb. each this year. The seed grows rapidly in nursery and stands transplanting and stumping the same as Arabian coffee, begins to bear at two years old, is a splendid shade, a hardy plant which no insect cares to touch and grows in the poorest soil. It bears all the year round ; once a week a cooly shakes the tree and picks up from the ground what has fallen off ; then drops the pods in the sun, shells them, then gives another drying which is all that is required ; the wood of tree is also very tough and stands the wind well."

We trust the Bostoners (at "the hub of the universe") will appreciate the enterprize of the proprietor of Maria estate, and that large orders for Ceylon croton seed will result from the Exhibition.

A MODEL PLANTATION AND FARM.—We cannot help calling attention to the advertisement offering a Dimbula plantation for sale, in our columns today. Unfortunately, plantations are not rare commodities in the market in Ceylon at present : the would-be sellers of coffee estates far exceed the number of purchasers :—in many cases, it is true, the seller will tell us

My poverty, but not my will consents.

Be that as it may, it must be confessed that there is something unique in the account given of the Holbrook plantation now in the market. What would the rough and ready planters of thirty or twenty years ago—whose horizon was bounded by coffee and coffee only—say to the combination of money-making arrangements on this Holbrook property? The yield of coffee has surely been enough, of itself, to satisfy proprietors during the hard times lately experienced ; an average of over 6 cwt. for six years carries us back to the palmiest days of the local enterprize ; but what would poor "Sandy Brown" (of the "Planters' Manual") say to the fifty thousand of flourishing cinchona trees, besides the twelve acres of this product, yielding, from an annual shaving merely, a crop equal to the richest return from coffee. It is the dairy produce, however, which has chiefly arrested our attention, for Mr. Saunders seems to have solved the question on Holbrook of maintaining a suitable cattle-manuring establishment for his coffee, with a due return from the dairy and the butcher. Surely this example can be more widely followed, more especially when the railway opens up our highest plateaux to permanent settlers and a multitude of visitors.

COFFEE ON THE SHEVAROYS.—We hear that the prospects of the coffee crop on the Shevaroys are this year very fair and that, after two rather unfavorable seasons, the planters are likely to get a small return for their labors in the past three years.—*M. Standard.*

A BRAZILIAN COFFEE EXHIBITION.—Senor De Medonca, the Brazilian Consul-General here, has just opened a really creditable exhibition of samples of Brazillian grown coffees. An office at Broadway has been arranged for the display, and when I dropped in there were over 1,000 different samples for many diffeerent plantations and showing the differences created by care in seed and improved methods of cultivation. The show has been visited by the members of the Coffee Exchange who deal largely in "futures" on Rio and they admit that Brazil must greatly benefit her trade by this public exhibition of her staple. Why cannot enterprizing Jamaicans get up such an exhibit here of their products ? It would stimulate trade and prove mutually beneficial.—*Gall's Jamaica News Letter.*

HEAVY RAINS IN COORG.—Mercara, 14th July.—Thanks to our enterprizing merchants and shopkeepers both European and native, we have stored up sufficient food to last us for a month at least, but the price of provisions has doubled. Raggi for the coffee estate coolies, rice for the Coorgs, and wheaten stuffs for foreigners, can only be procured from those who were wise to have them etored up. Butcher's meat is very little at 8 as. a pound : this means mutton of course. Beef is only to be obtained by going out of the country : in Coorg it is never sold. What is the reason of this famine? I answer, the rains which have been fearful, tremendous and contiuuous. In the mooth of June 95 inches fell. In July, to the date of my letter, 75 inches more, and in one day over 14 inches fell. It is now found that of the four trunk roads leading into Mercara, not one is passable. The oldest inhabitant, a man who has been in Coorg 14 years, says, he remembers such another monsoon, which was, if anything, worse than this. But it was the year before he came up.—*Madras Standard.*

COFFEE-LEAF DISEASE.—Abstract of paper read before the Linnean Society :—"Mr. Marshall Ward read a paper in his researches on the life-history of *Hemileia vastatrix*, the fungus of the coffee-leaf disease. The phenomena attendant thereon show great analogy to those of the Uredine fungi. The spores under favonrable conditions, viz., moisture, a due snpply of oxygen and a temperature of 75° F., usually germinate in from twelve to twenty-four hours. Complete infection or establishment of the mycelium in the intercellular passages of the leaf occurs about the third day after the formation of the germinal tubes. The so-called yellow spot or ordinary outward visible appearance of the disease, manifests itself about the fourteenth or fifteenth day, but may be delayed ; its development and course being dependant on secondary causes, such as atmospheric conditions, monsoon, age of coffee-leaf, &c. By watching the progress of the spots it has been ascertained that the spores therefrom may be continuously produced for from seven to eleven weeks or even more. Some 150,000 spores have estimated as present in the yellow clusterspot, and as 127 disease spots have been counted in the pair of leaves, the quantity of spores thus regularly produced must be enormous. According to the amount of diseased spots, the sooner the leaf falls, and though young leaves arise, the fruit-bearing qualities of the plant necessarily are interfered with. The various sorts of coffee plant are all liable to infection ; the only possible remedy is the difficult one of destruction of the spores, and these are supposed originally to have been introduced from the native jungle, and rapidly spread under the favourable conditions of artificial cultivation."—"Nature," June 15th, 1882

TEA IN CEYLON.

Ceylon tea is beginning to attract its due share of attention in business circles at home, and there ought to be little difficulty now in obtaining the support of mercantile capitalists to extend an industry which, according to Mincing Lane authorities, has everything in its favour in this island, save a sufficiency of skilled supervision for the preparation of the leaf. The want can be readily supplied from India to the satisfaction of capitalists, so that the promoters of a Dolosbage, a Yatiyantota, Ambagamuwa, Maskeliya or Adam's Peak Limited Company for the cultivation of tea should be readily patronised among the men who have so liberally developed the tea districts of Northern India. Ceylon presents to home capitalists very important advantages, and, as we said, the only alleged drawback is one which time is steadily rectifying, but which can be removed at once by a well-managed Company.

In addition to the supply from India, we may shortly receive an increased quantity of tea from the new field now being developed in Ceylon. To the present, the quality of teas from this quarter has not proved so satisfactory as could be desired. Ceylon ought to do well, as it has the advantage of a climate equal to that of Darjeeling or Assam, it being practicable to have plantations on the higher ranges as well as in the valleys. Owners of estates, must take care not to repeat the mistake made by the first planters in Assam. This mistake was the employment of managers, who, if competent to *plant* tea and manage the estate in other respects, failed to recognize the absolute necessity of care in *manufacturing*.

The unsatisfactory prices recently obtained, arise plainly from neglect of the first principles of manufacture. We offer the suggestion, that owners of estates in Ceylon should insist on a rectification of the neglect. It is a well-known fact that teas yielding a thick malty liquor will sell anywhere in the United Kingdom at fairly steady prices, whereas teas of a thin but fine and delicate flavour are subject to violent fluctuations in price, and even when there is a demand for such qualities, it is but temporary and local. The aim of all managers should be the production of a sound, useful tea, not coarsely plucked however. For the purpose of mixing with China sorts, there is always a large demand for thick malty teas.

Capital alone is wanted to give a proper impetus to the extension of tea cultivation in this island: virgin forest-land at a high or low elevation is available; labour can be had in abundance; planting supervision of the best on moderate terms; skilled supervision for manufacture is at hand; transport is very convenient and cheap and climate is vastly superior to that of most of the Indian tea districts.

THE CINNAMON TRADE.

It is evident from the recent correspondence in the local Ceylon papers that the prices at which cinnamon has been selling in this market, especially at the last few quarterly sales, have not been remunerative to growers. This is the case even with those who ship direct on their own account, while to those growers who sell to merchants on the other side, the present values must be even less profitable, as the merchants to whom they sell can only make offers to show them a profit on public sale quotations, after taking into consideration the expenses of freight, loss in weight, dock charges, and so on. In this, as with all other commercial productions, the price realized is of course simply a matter of supply and demand, and the present statistics show that the former is far in excess of the latter. The stock here has increased gradually year by year, and is now no less than 7,292 bales of Ceylon, 1,412 packages of China cinnamon, and 4,641 packages of chips, against a total last year of 5,994 packages of Ceylon and China cinnamon and 3456 packages of chips. This very heavy stock, of course, greatly depressed the market, and at the last quarterly sales in May prices dropped to the extent of 4d. to 6d. for fine to superior qualities, and 2d. to 3d. for inferior to good sorts. The system of quarterly sales, which survives as a relic from a former state of things, no doubt materially aggravates the evils from which the growers in Ceylon suffer. They are kept out of their money for an unnecessary period, and the stocks accumulate over a period of thirteen weeks, until they reach an immense total. When the sales finally take place, a crushing quantity is offered, and prices are unduly depressed, to the benefit of speculative buyers and the injury of planters. The sales of cinnamon, in the interests both of the growers and of the home trade, ought to be held from week to week, just as is done with any other commodity. There is no virtue or peculiarity in cinnamon that necessitates its being sold in a different way to other things. Even monthly sales, instead of quarterly ones, would be decidedly a step in the right direction, for the present system of quarterly sales only multiplies speculative buyers, who buy largely to supply orders that come into the market during the three months without sales, and thus obtain a profit which the planters ought to get. For instance, export orders that cannot be held over for the quarterly sales have to be executed at a profit from second-hand parcels in the market. Dealers also have to buy largely for a three months' stock, to avoid having to buy between the sales, and have thus to hold more cinnamon than they would need under a more reasonable system. Here, again, it is the planter who has to pay. Some of the correspondents of the *Ceylon Observer* recommend that chips should not be sent to this market. This, however, appears a short-sighted policy, which would simply stimulate the demand for cassia and China cinnamon if the price of quill Ceylon should rise, which appears very doubtful, though broken cinnamon might do so. If weekly or monthly sales were established they could not in any way tend to decrease the demand, but they would render it more even, would make realizations more prompt, would save interest and dock charges, would throw open a sort of small monopoly; and while bringing better prices to the planter, would be beneficial to the dealers and shippers by interfering with the operation of the speculative buyers.—*Produce Markets Review.*

CHINESE AND CEYLON TEA.

Very considerable attention is being attracted in Chinese quarters to the present condition of the tea trade, and those who know most about the subject will be the least surprised to hear that for several reasons it is not regarded as perfectly satisfactory. In the first place, whereas China long enjoyed a monopoly of the trade in this article, she has now to cope with more than one enterprising competitor. India has for some years competed with her on not unequal terms in the London market; and, unless the present signs are totally misleading, Ceylon will very shortly be in a position to challenge the superiority of Orange Pekoe or Flowery Congou. In the United States, Chinese tea has also been ousted to a great extent by that of Japan. Many say that China has seen the worst in this matter, and that the foreign demand for her tea is not likely to decline any further. This belief may or may not prove well-founded, but the

Chinese are evincing wisdom in not showing themselves indifferent to this tendency. It is easier to note the evil than to assign the cause or to fix the remedy. Several circumstances have contributed to the decline of Chinese tea in popular favour. Over competition among Chinese planters and merchants appears to have resulted in a deterioration of the quality of the tea itself. What are called best "crops" are distinctly inferior to what they were ten years ago, and the main cause of this falling off seems to be the over haste shown in despatching tea from the fields to the market. The principal object with both the Chinese and the English merchant in China appears to be not to send the best tea so much as the earliest tea on to the market. If persisted in, this must prove a suicidal policy. There are, no doubt, several other reasons. It must also be borne in mind that tea is a heavily taxed article, and one also out of which many different persons have to derive a profit before it reaches the cup of the consumer. The Chinese Government derives, by the export duty, about 3½d. from each pound, and our own tax on it is still expensive.—*Globe.*

THE CEYLON AGRICULTURAL ASSOCIATION.

The Committee members then presented their report on the subject of the exportation of Cinnamon Chips in accordance with the VIIIth Resolution, and it was resolved that the same be printed and circulated amongst the members of the Association, and that a general meeting be called for the 19th August 1882, at 1 p. m., to consider this subject and other matters that may be brought forward.

In terms of Resolution VIII passed at a general meeting of "The Ceylon Agricultural Association," held at this office on the 24th June last, the Committee of the said Association beg to submit the following report on the subject of the exportation of chips.

On referring to the Chamber of Commerce returns, the following are the figures appearing, showing the exports of Cinnamon, quills and chips, for a series of years.

Total quantity exported from 1st Oct. to 30th Sept.

	Quills: bales.	Chips: lb.
1872 ...	10,327	235,135
1873	10,232	242,547
1874 ...	10,825	183,303
1875 ...	9,027	200,607
1876 ...	12,622	258,381
1877 ...	10,631	284,664
1878 ...	12,983	259,174
1879 ...	12,192	188,518
1880 ...	13,955	474,484
1881 ...	13,194	321,772
10 months 1882 ...	10,288	358,003

It will be observed from the above, that the export of chips has gradually increased, till in the 10 months of this season there has been exported more chips than was shipped in any one season during the past 10 years, (with the exception of 1880, when the enormous quantity of 474,484 lb. were exported), and during the remaining two months of this season, it is expected that a further quantity will go forward.

It is well known that, at every quarterly sale of cinnamon in London, there is a larger quantity of spice offered for sale than can find purchasers, and the consequence has been unprecedentedly low prices for quills, and a large addition to the stock, and as long as chips are at hand, and can be obtained at 2d to 3d per lb., against 2s to 3s the rates for quills, it is not to be wondered at that competition for the latter is anything but satisfactory. The Committee trusts that, cinnamon-growers will see the necessity of stopping entirely, or at least reducing, the quantity of chips for shipment to London and other markets, and so, to a certain extent, increase the demand in the London market for quills, and the advance in rates will assuredly be corresponding.

In this connection, the opinion of an eminent London firm, long in the Ceylon business, is worth every attention. To an enquiry regarding chips they write:—

"With regard to your proposal to keep back your chips and send them to the distillery, we do not think it would make much difference if one shipper was to do this. Of course *if all shippers* would agree not to send forward any chips for 12 months, it would strengthen the position of the market for the quills."

The Committee, under these circumstances, trust that all members of this Association, who are interested in the cultivation of cinnamon, will join in doing their utmost to stop the scraping of chips on their estates, say for a period of three years, save for the purposes of their own stills and those of their constituents.

Colombo. July 28th 1882.

Resolved:—"That the Secretary be requested to address the agents or proprietors of Galluapokena, Kimbulpitiya and Ratmalane estates, and to invite their co-operation in this movement for the suppression of the trade in chips, as injurious to the interests of cinnamon proprietors."

It was also resolved that, at the next general meeting, interpreters be employed to convey what passes, in Sinhalese and Tamil, to such members as may not be acquainted with English.

Resolved:—"That the Secretary do write to proprietors who have not already joined and invite them to join this Association."

Read letter from Mr. Laker MacMillan, F. C. S., dated Calcutta, 15th July 1882. *Resolved*:—"That the Secretary do write to Mr. MacMillan thanking him for the offer of his services as honorary consulting chemist of the Association."

Resolved:—"That a vote of thanks be accorded to the chair." S. PETER SOYSA, Secretary.

Colombo, August 1st, 1882.

"WHAT AILS OUR COFFEE TREES?"

Such is the heading of a letter signed "W.," which will be found on page 244. Those who have attentively perused the articles which appeared in the *Observer* recently, and which will be found in the leading pages of the most recent edition of the *Ceylon Handbook and Directory*, will see that we attach much importance to abnormal seasons and exceptional meteorological conditions as factors in the terrible change for the worse in the fruit-bearing powers of the great staple product of Ceylon, Arabian coffee. Elaborate calculations were made and important figures quoted to prove the especially adverse influence of abnormal rainfall in the blossoming season. We have nothing to say against "W."'s position that, in common with that of a large portion of the world, the agriculture of Ceylon has suffered for a series of years from abnormal weather—from disjointed seasons, the causes of which are beyond human ken; unless, indeed, we fall back on the effects of solar disturbance, the mention of which "G. W." as carefully avoids as the use of the little, but in our estimation sadly potential, word "GRUB." Surely this latter omission, in a letter professing to trace the causes of the fearful depression under which the leading industry of the island (it is still that) suffers, is worthy to be ranked with the most curious of literary, scientific and metaphysical phenomena of our day. So is also the developed tendency of so practical a thinker to suggest occult causes, and undervalue the gravity of symptoms which lie either on the surface (*hemileia vastatrix*) or not far below the surface (*white grub*). The latter, as we have said, is utterly ignored, while "W." makes light of the fungus

as a primary agent in the production of the present crisis. In neither respect can we agree with him, any more than in the position taken up that the visitation of the fatal fungus was due to predisposition of the trees to be injuriously affected. We think it will be universally admitted that never was coffee in Ceylon better cultivated, more vigorous, more fruitful than in 1869. That was the year of our culminating crop and simultaneously came the development over our cultivated coffee of a fungus which, beyond doubt, had been previously latent on the allied trees of our jungles. Some of the cultivated coffee was of course debilitated from age, but a large proportion was young, and of this description a great addition was made to that existing in the half-dozen years which followed 1869. Additions were made to existing cultivation in that period at a rate entirely unprecedented. Prices of coffee were good, and planters, until taught by bitter experience, refused to take the same serious view of the effects of *hemileia vastatrix*, which scientific onlookers held and expressed. We had all to learn, what "W." apparently wants us to unlearn, that the minute fungus which had so suddenly and mysteriously appeared was the deadliest foe which coffee had ever encountered, a foe which, while it no doubt told most heavily on old and debilitated trees, did not spare the youngest and most vigorous, but attacked them repeatedly and pertinaciously, feeding on their life-blood, and so gradually reducing them also to such a condition of debility, that to them the double task of keeping up successive crops of foliage and still producing fruit became impossible. No doubt the virulence of the attack varied in different seasons, in different districts and on different estates. Constituents of soil, the presence of manure, the effect of tillage, light and heavy pruning, the presence or absence of weeds, and—a most material factor in the case—the presence or absence of grubs at the feeding rootlets of the tree—all told. The recuperative powers of the coffee trees, too, especially of the younger ones, and the instinctive tendency to fruit the more existence was threatened, must not be forgotten. Hence the capricious results which "W." would trace to seasons and occult influences, alone or mainly, underestimating the effect of fungus on the leaves and utterly and unaccountably ignoring the destruction of the feeding rootlets of the trees, whereby the candle of life was burnt at both ends. And coffee suffered, has suffered, does suffer, from the *indirect* as well as the direct effects of a fungus which, like the white ant in the case of cocoa and other plants, does not wait for conditions of decay to attack vegetable tissues. We have heard of planters recommending the remedy for grub of so feeding them with manure, that they might be diverted from preying on the rootlets. The remedy proved very questionable as regarded the cockchafer grubs, while in the case of the fungus, planters who manured heavily found, over and over again, that most of the fertilizing substances supplied to strengthen the coffee bushes went simply to feed fresh crops of parasites. What wonder then, if owing to such experience and the absence of paying crops, manuring was given up by many in despair; by many others from sheer inability to bear the necessary expenditure. The *prevalence* of fungus and grub may be and no doubt is due to abnormal seasons, those abnormal seasons being again due to "W."'s "occult" causes. But we cannot and dare not undervalue the effects of the specific pests while they exist, any more than we should venture to disregard the external and obvious symptoms of enteric or jungle fevers, because we know that the one is due to foul water or mephitic gases, while we infer that the other is due to an occult cause to which we give the name of malaria. Had "W.," instead of taking for granted a predisposition in our coffee trees to the attacks of the fungus which developed in 1869 and onwards, adopted the position that our exclusive devotion to one product, with which we had covered vast unbroken expanses, was to blame, as an outrage on the general arrangements and laws of nature, we could understand and largely sympathize with him. Indeed, if we are at liberty to infer the designs of Providence from his dispensations and their effects, the disaster which has overtaken our coffee culture, like that which previously desolated the potato crops in Ireland, was intended as a punishment for a too exclusive devotion to one food product and an incentive to the cultivation of a more varied list of plants—"new products," in fact. Unhappily experience has led us but too largely to agree with "W." as to the hopelessness of the attempt, by topical applications, to banish the ubiquitous leaf fungus. Its powers of reproduction are such that, if a particular estate or group of estates could be cleared this month, the chances are that they would be as badly affected as ever the next.

We cannot, however, agree with "W." in the fear that, if the pest were completely got rid of, it would be certain to reappear in its pristine destructiveness. We have the history of the black bug or scale insect to guide us. That pest also existed in our jungles, but after a more obvious fashion, and with much more cosmopolitan tastes than are characteristic of the coffee leaf parasite. As the result, no doubt, of the presence of an expanse of suitable food and the occurrence of abnormal seasons, black bug nearly forty years ago suddenly swept like a deadly epidemic over the whole of the cultivated coffee of Ceylon. Whole valleys and mountain sides turned from healthy green to funereal black, and the fear entertained regarding bug then, as it is in reference to the fungus now, was that it would prove the absolute destroyer of the coffee enterprize. Topical applications, such as dusting with saltpetre, &c., were as ineffectual then as lime, sulphur, carbolic acid, &c., have been in the recent fight against the fungus. But (and now we are again with "W." as to the potent influences of seasons and the occult influences which guide their character) the seasons changed after the disastrous years 1846 to 1849; black bug disappeared, and, instead of its coming back and being a bad as ever, as "W." fears will happen in the case of *hemileia*, it has never since given the planters much trouble, being confined to small exceptional patches of coffee estates, and affecting crop to no appreciable extent. What has happened in the case of black bug, we have a right to look for in the case of *hemileia vastatrix*. We are experiencing—thanks probably to to the more or less occult influence of "sun-spots," as the solar whirlwinds are called—an abnormal season, and planters, whose opinions are worthy of respect, are most hopeful that the result will be to drown out both fungus and grub. If the pests once disappear, our reasonable hope is that, although they may not be blotted out of existence, their reappearance will not be in a deadly epidemic form, but in the shape of slightly sporadic attacks, sufficient merely to keep planters on the *qui vive* and to prevent their neglecting any precautions against the old exhausted foes or such new ones as are possibly destined to develope with reference to new circumstances. The "thorns and briers" curse has a reality and an extent which we can recognize, however little we can understand that and a thousand other mysteries of our nature and our environments. That the same

benevolent BEING should be the CREATOR, not only of the cattle and the herbs which are good for the food of man, but also of destructive parasites, insect and vegetable, which so often defeat man's best efforts and ruin his resources, would seem to present a problem as insoluble as the existence of moral evil. In the one case, as in the other, man's duty, which often becomes a pleasure, is to fight strenuously and valiantly against adverse influences, trusting to overcome them, by strength not his own. In the case of the natural evils now under review, our immediate duty seems to be to avail ourselves, as far as possible of laws which are obvious and which to some extent we can control, trusting to the operation, sooner or later, of the larger and less explicable laws which we can understand only after they have operated for long periods and over wide areas. We hope we shall not be misunderstood. We only disagree with "W." in as far as he makes light of such specific evils as fungus and grub,—the latter of which he does not even mention! We most heartily approve of his suggestions that planters should attempt to trace out and so be able to supply the conditions under which exceptional trees, or patches of trees, are found to resist disease. We should, however, be sorry to discourage any experiments at *cures* for fungus or grub which planters may feel inclined to institute. But as meteorological phenomena have been, we believe, the main agents in the development and continuance of these two destructive pests, our main hope of relief—and it is strong—is founded on the evidences recently presented of changed seasons such as we believe to be adverse to the abundant existence and deadly operations of some of the worst ENEMIES OF THE COFFEE TREE which have ever appeared in Ceylon.

RIVAL QUININE-GROWING COLONIES.

The two Colonies of Jamaica and Ceylon—separated by so wide a distance, but so nearly alike in agricultural resources—are running a close race with each other for first place as quinine-producing countries. Ceylon, which was in the field first, naturally has the advantage of longer experience; but Mr. Morris, who took with him to the West Indies all the information which his career in the East had enabled him to collect, has shown that Jamaica well knows how to make up for lost time. Meanwhile planters growing for profit, and the official botanist growing for experiment, in Ceylon, are placing the cultivation of the different varieties of cinchona on the level of a science. The particular virtues of *succirubra*, *officinalis*, *calisaya*, *cordifolia*, *lancifolia*, and others are accurately weighed, and their suitability for different kinds of soil exactly ascertained, while anything that seems to be a new variety is eagerly tested at the Government Botanical Gardens at Peradeniya. Mr. Trimen, in his report on these gardens for the year 1881, states that bark of excellent quality has been obtained from a cinchona tree, whose exact species seems in some doubt, but which is believed to be a hybrid, originally brought into the island from the Indian Government plantations in the Nilgiris, which has assumed a permanent form. Whatever its origin, its produce is proved to be very valuable, and Mr. Trimen proposes to christen it scientifically *C. robusta*. He strongly urges the exercise of the greatest care in the examination of all plants raised from seed which do not come true to type, and he recommends propagation, wherever possible, by cuttings instead of from seed. One great principle which distinguishes the system of Government encouragement in Ceylon from that adopted in Jamaica, is, that while in the former island the Government does not enter the market as a producer of bark, the principal supplies of cinchona received from the latter island are grown and sold by the Government. Mr. Trimen thinks, and properly so, that it is not the duty of the Government to enter into competition in such a matter with private enterprize. Perhaps when cinchona cultivation promises to be as largely adopted in Jamaica as in Ceylon, the authorities there will confine their attention to the experimental culture of new varieties.—*Colonies and India.*

VANILLA FROM OATS.—It is well known that the German chemists Thiemann and Harmann, some time ago succeeded in preparing artificial vanilline from the sap of pine trees. A French chemist, M. Engéne Scrullat, has discovered a way of producing the same compound from common oats. The hull of the oats contains a principle which is very soluble in boiling water, and to which M. Scrullat has given the name of Aveneine. This principle is isolated from the residues of manufacture of oat meal, is oxydized, and becomes converted into the characteristic perfume of vanilla. Whether it has all the properties of vanilline, as made from the bean and the sap of the pine, remains to be determined.—*Oil and Drug News.*

MYSORE, July 24th.—Weather this monsoon has been exceptionally severe both as regards wind and rain. During the 16 years I have gauged the latter nothing like it had previously fallen. The fall here (Igoor) is about a fair average one for the coffee districts of Mysore, and is about 110 inches annually, and this year 145·79 inches has already fallen, of which 50·49 and 86·49 respectively for June and the unfinished part of July. The nearest approach to this hitherto was 57·90 in July 1876, but with only about 15 inches month before and after, and again in June 1874, 50 inches followed by 43·69 in August. The maximum annual rainfall hitherto was 145·16 in 1874, and minimum 90·67 in 1881. We may expect monsoon rain for another 3 or 4 months.

THE TREATMENT OF SEA-SICKNESS.—Dr. Milan Soule surgeon on the steamship "City of Sidney," has written an account of his experience with the bromide treatment of sea-sickness as laid down by Dr. G. M. Beard. His testimony to its efficacy is very emphatic and convincing. He says: About three years ago I began to use the bromides in treating sea-sickness, following as nearly as possible the directions given in Dr. Beard's valuable monograph on that subject. I had then been in the service of the Pacific Mail Steamship Company nearly four years, and as my field for experiment was large, I had tried nearly every drug or combination of drugs that had ever been proposed for the cure of alleviation of this disagreeable malady. Repeated failures and humiliating disappointments had so shaken my faith in the power of drugs over this disease that I began to use the bromides with a good deal of doubt and hesitation. Greatly to my surprise and gratification, however, I found that I was able to entirely prevent or greatly alleviate the disease, and not one single failure to record. The following is the combination I most frequently employed viz:

Bromide of Sodium ....drachms four
Bromide of Ammonium..... ..... ,, two
Peppermint water.....fluid ozs. three.

A teaspoonful before meals, and at bed-time; begin treatment three days before going on board.

When preparatory treatment has been neglected, and the disease fully established, I put a teaspoonful of the above in a half-tumbler of water, and a drop of extr. ipecac. fld. and give a teaspoonful every five minutes, it generally relieves the patient in less than an hour. I have received several letters (guinea inclosed) from passengers asking me to send them the above formula. Next to the bromides, I have found hyoscyamia the most successful remedy. Atropia will frequently afford relief, but is not altogether safe as I have noticed a few cases of retention of urine to follow its use. I gave nitrite of amyl a fair trial, but it proved a complete failure. I have notes of several cases where the bromides entirely prevented sea-sickness during voyages of from twenty to thirty days, although these patients were always sick on previous voyages.—*Medical Record.*

Correspondence.

To the Editor of the Ceylon Observer.

THE "CEDRELA TOONA" AND ITS INSECT ENEMY.

Houses of Parliament, Brisbane, 1st June 1882.

To the Editor of the Tropical Agriculturist, Ceylon.

SIR,—I was much interested by the account given, in your issue of 1st February, of a borer which attacks the young trees of *Cedrela Toona* in Ceylon; because the same thing has come under my observation here, where the tree is also indigenous. As I write I have within sight two trees eleven years old which are little better than stunted shrubs from this cause. Year after year the tender shoots have been attacked in the manner described, the grub commencing at the terminal point and eating its way until, apparently, the shoot became too woody for its operations. These are the only cases shewn to myself, but I have heard of others where the trees has been artificially planted.

This season is the first in which my trees have escaped, a circumstance probably attributable to a succession of very dry seasons which have had a disturbing influence upon much insect life. We have no entomologists in Queensland except a few dilettante butterfly collectors, and I have therefore not been able to learn to what insect the injury done to our young cedars is attributable. If however the subject is likely to be of any importance to Ceylon, I shall be glad, on the first reappearance of the grub, to send specimens for your determination.—Yours faithfully,

LEWIS A. BERNAYS.

[We shall be glad to receive specimens: it is strange the tree should suffer so much if indigenous to Queensland.—ED.]

THE CEYLON PLANTING ENTERPRIZE AND THE PROSPECTS OF OLD AND NEW PRODUCTS.

12 Great Tower Street, London, June 30th.

SIR,—In reading your leading article in the *Overland Observer* headed "The Tropical Swing" I was glad to find you bear out my own stated views as regards the continuous shortness of the crops in the chief districts on the Kandy side of the country (in contradistinction to the Uva side) to be owing to rain in February, and not to debility in the trees from leaf-disease, as so many suppose.

It would be interesting to compare the rainfall return for January, February, March and April, for the last ten years with the crop returns of some of the leading districts, say Dimbula and Dikoya.* I think the comparison would show that given fine weather from 15th January to end of February, with one or two thunder-storms at the most, the blossoms for the year, even if partially rained upon, will have produced a very fair average crop; and when the fine weather has been prolonged to the end of March or the first week in April (compare the Dikoya crop of 1878 and the great Dimbula crop of 1876) the crops have been a good deal above the average. My object in writing this is to help to point out that it is the badness of the last four blossoming seasons that is at the root of our present misfortunes in Ceylon, and not so much the fungus pest, as people at home especially seem to think. Leaf disease certainly has diminished the possible average crops from 7 or 8 cwt. an acre to 5 or 6, but it is not responsible, I maintain, where estates have been kept in heart, for the present miserable average of the last three crops, and the coming one, which will even reduce the average further in many cases.

We all knew with fair average crops and fair average prices coffee always pays well. A period of dry weather is perfectly essential to enable any fruit-producing tree to put out a *healthy* blossom. I was down in Kent in April last in the blossoming season, and never had there been seen a finer show of blossom. In addition to all the orchards there was not an isolated plum tree even in a cottager's garden all the way down from London, that was n't a mass of bloom. I attributed this to the prolonged drought dating as far back as last November interrupted of course by an occasional shower. I was not in England during the blossoming season of 1881, but I was told the drought was longer then and the blossoms apparently as heavy. I can vouch for it that the fruit season in Kent in 1881 was the best in quality and the most in quantity they have had for many years. The coming season will be even better, judging from the blossom, especially as there have been no damaging frosts to speak of, and nothing to injure the prospects, except a severe storm in May, which in some places did harm.

The fruit in many cases is sold on the trees before it is ripe, and I hear that the fruit of the cherry orchard, which is supposed to be the finest in England, has been sold for £100 more than last year. A good blossoming season not only means, I think, a large crop, but a good quality of crop. Both the quantity and quality of the Indian coffee crop this past season has been excellent, and helps with the large supplies from Costa Rica to flood our overladen markets.

The quality of last season's Ceylon coffee as a whole has been disappointing. It is very evident that the metereological conditions of Ceylon's atmosphere have been out of gear from some unknown cause, but that is no reason why they should continue so, and we may reasonably look for a series of favourable blossuming seasons again. I feel quite confident in my own mind that Ceylon will come round even more rapidly than one can just now hope for.

The position of Ceylon cinchona not only as regards present prices in the London markets but as regards the competition for it, and the new profitable methods of harvesting bark, is all that could be desired. If planters could only see the dullness of the South American bark sales at auction compared with those of India and Ceylon they would be much inspirited. The cinchona saleroom every alternate Tuesday is becoming quite a rendezvous for Ceylon planters in England.

I am engaged in collecting the statistics of the importations of bark into the different European countries and America for the last five years, and hope shortly to finish my researches. As far as I have at present gone, the increase everywhere is of a most encouraging nature, both as regards quantity and value.

I think it is a great mistake to send home any bark that is not likely to realize 1s per lb. A slight loss owing to a small proportion of bark being required for samples will not be felt or noticed when shipments change from 500 lb. to 50,000 lb., as the same amount for samples would be sufficient in either case.

Any estates that have gone in largely for cinchona would do well to establish their marks in England, in the event of an overstocked market, when known and tried marks would probably have the first attention of the buyers.—I am, yours faithfully,

JOHN HAMILTON.

* This can be done on a reference to our Ceylon Handbook for 1882, where we give a table of rainfall during the blossoming season for a number of years.—ED.

MODIFIED OPINIONS REGARDING WEEDS AND PRUNING IN COFFEE CULTIVATION.

Peermaad, Travancore, 23rd July 1882.

DEAR SIR,—I shall be glad if you will find space in your valuable journal for the following remarks which I hope will bring forth some discussion.

There are two points on which I have for some years held a decided opinion ; one is that weeds are without exception an evil and a source of loss to the proprietor of an estate ; the other that by an early or late pruning one could force the coffee trees to mature their wood and so get a somewhat earlier or later blossom. I have lately altered my opinion on both points.

I know full well that the negative of my first question will be run down by an enormous majority of planters, but I trust some instead of scoffing will give me the benefit of their experience and views. First let me give a brief outline of the district, for it is peculiar. I have charge of several estates in a valley through which a biggish river flows. The estates are surrounded on all sides by high hills. The elevation is about 2,600 to 2,900 feet ; but this can give no idea of the climate, the heat being more like that of the lowcountry than the hills. The soil is as fine as any I have seen anywhere. Neither Haputale nor Dumbara can beat it. Taking one thing with another the district bears a striking resemblance to that of Dumbara. The rainfall has not been kept for an entire year, as I was away last September and the gauge was not kept during my absence, but from July 1881 to June 1882, I registered 63·66 inches on 115 days, over 26 inches of which fell in June. From January 3rd to March 27th not a drop of rain fell—a period of 83 days drought. In November and December we had very forcing weather, constant light showers and hot sun. The blossom was therefore very forward by the end of the latter month, and the rain at the commencement of January brought out a nice sprinkling of blossom, which set well and very materially helped on the big spike that was before well advanced. It is hardly necessary for me to say that an enormous percentage of the spike was burnt and was knocked off the trees by the first rains.

In former years these estates have invariably had regular and heavy dews ; indeed I am told they have sometimes been so heavy as to open and set blossom. Last year this estate was fairly clean all the year round ; I then had but little dew. This year the estate has been clean and the dews have been practically an entire failure ; while other estates that have been weedy have had more dews and have set their blossoms well. From this there is, I think, but one inference to be drawn, and this is that by having a carpet of green weeds during these three dry months there would be less radiation and the ground would be kept comparatively cool and moist in place of being baked up and having every particle of moisture drawn out of the soil. I may mention that the ground was so hot that it was painful for coolies to walk without sandals. My present theory is that, if the months of November and December are forcing and the blossom is well advanced by the commencement of January, it would be better to drop weeding from January to April. During these months a peculiarly succulent kind of keerie springs up and thrives, I may say to the exclusion of all other weeds. It disappears after the first weeding when the rains have set in. If on the other hand the blossom is backward at the commencement of the year, I am of opinion the estates could not be kept too clean as it would serve to ripen wood and force the blossom. I have always looked upon weeds as one of the planter's worst enemies and still do so under ordinary circumstances. But I think this is a case in point where circumstances alter cases.

Next as regards pruning. One part of this estate I pruned in January 1881. Now if the theory that early pruning assists the wood to maturity be correct, this field should have had more blossom burnt than any other, as it was pruned first. It has a crop of 8 cwt. an acre now on the trees. Part of the estate which I gave a heavy knife handling to in May 1881 gave a crop and matured it of 15 cwt. per acre, and this year is giving nearly 10 cwt. I have therefore come to the conclusion that the rate at which wood matures depends not on the time of pruning, but on the condition of the tree itself or in other words the amount of vitality it possesses. Of course some seasons are more favourable for the ripening of wood than others. But given any one season I think infinitely more depends on the disposition of the tree itself than on any artificial means, such as an early or late pruning.

I consider the *Tropical Agriculturist* a journal of the highest value as a medium for promoting useful discussions on all planting matters, as it has such a large and extensive circulation in all parts of the world. It is therefore in the hope that some may have had the same experience as myself that I venture to ask you to publish this letter and beg for the opinion of my fellow-planters.

What do the faculty consider to be the proper distance for planting calisaya robusta and succirubra cinchonas ?*—Yours truly, JOHN S. SEALY.

P. S.—The area of coffee with 8 and 10 cwts per acre is but small.

NEW PRODUCTS : "INDIARUBBER AND GUTTAPERCHA."

"If you wish success, make perseverance your bosom friend, experience your wise counsellor, caution your elder brother, and *hope* your guardian genius."—ADDISON.

July 24th, 1882.

DEAR SIR,—Planters have to thank you for this year's latest "compilation," and it is only a matter of surprize that it has not been more noticed in your columns, but doubtless its contents are being well digested by many.

The notes and reports on pages 42 (on Chavannesia esculenta) and 48 (on the methods of collection and preparation) are very interesting and valuable, but Mr. Cross's reports are most generally unreliable and Mr. Borrow has most sensibly criticized and condemned some of his statements, page 75. That gentleman has done great service in the collection of plants, but his *accounts* are romantic and should be taken *cum grano salis*. The extract on page 72 is repeated again on page 81—word for word—but you may have intended this, by way of drawing attention to Dr. King's experience and cautious advice ! On page 102, it is recommended to plant Heveas (Pará) in alternate lines with cocoa. Has any one tried this ? Should it succeed, what a grand combination ! Rubber shadetrees and cocoa !—comparable with ledgers and cardmoms.

That is a very interesting article (from the *Indian Agriculturist* of March 1877) on page 99, but on page 27 reference is made to the Chavannesia esculenta : "instructions for its cultivation have been recently published in the *I. Agriculturist*." Can you reprint this for us in the *T. A.*, as the wonderful climber might succeed better here than in Calcutta ?† The notes on page 78 by Warnford Lock are true and to the point. On page 74 "Sceptic" estimates 109 trees (Cerâ) to the acre, but a planter writing in the *Observer* of September 19th, 1881, recommends 500—a far more sensible suggestion, *i. e.*, about $10 \times 9 = 484$ per acre : half the distance apart quoted by "Sceptic" and more than four times the number of trees per acre.

* See Owen's *Cinchona Manual*.—ED.

†We shall endeavour to do so.—ED.

Mr. Cross says on page 98 :—"A Castilloa tree . . . may be expected to yield 12 lb. of rubber per annum," but "E. M. H.," page 9, states that a tree "20 to 30 ft. high to its first branches, and about 4 ft in. diameter, is expected to yield 20 gallons of milk," equal to about 40 lb. of rubber.

The cultivation of *Ficus elastica* is not likely to pay Ceylon planters from its poor yield, slow growth, low prices, and the fact that it ought to be tapped, only once in three years, but the climber *Urceola elastica*, a native of Borneo and Sumatra, "of very rapid growth and gigantic dimensions is said to yield by tapping from 50 to 60 lb. annually" (page 19)! Has Dr. Trimen any plants of this variety at Peradeniya or Henaratgoda?

I have tried tapping *roots* of Cerà, and find plenty of milk exudes, but query whether this would not tend to kill the goose that lays the golden eggs? It thrives better than the more valuable Prà at present but we may not have hit off exactly the right locality for the latter in Ceylon yet, and it is worth persevering in, being the most valuable of all rubbers.

The Vaheas make a terribly slow growth at first from my experience, but, perhaps, the manager of the C. C. L. will tell us how they and the Landolphias are getting on now on the several estates tried.

That rubber will pay in many parts of the island, and in combination with other new products, there can hardly be a doubt, and the sooner Dr. Trimen returns and lets us know the results of the "further experiments" (see page 108) he promised would "be shortly made" in tapping the Cerà trees at Peradeniya, the better for those interested, it being just a year since the "preliminary and tentative investigation to ascertain the condition of the milk" in the Cerà tree was then made!

I wish your new Manual every success, and hope information will so readily accumulate that a new edition will be rendered necessary ere long.—Yours faithfully, TRY.

ENEMIES OF CARDAMOMS.

Ceylon Company, Limited, Colombo, 28th July 1882.

DEAR SIR,—I send you a tin containing some cardamoms received from an estate near Kalutara. You will observe that some insects—I think ants—have penetrated the covering of the seed and eaten the contents. If you or any of your correspondents can give me a hint as to the best way of preventing this destruction to one of our new products, I shall be very much obliged. ENQUIRER.

[It is the opinion of a good authority that the cardamoms have probably been attacked and the seeds eaten by some night-feeding caterpillar or grub. The superintendent of the estate should search for it after dark, or very early in the morning. Ants are not likely to have done the mischief; but in hunting for food they may enter the cavities made in the cardamoms by the insect that should be looked for. —ED.]

THE JAK TREE (TWO SPECIES); MANURING COFFEE AND H. V.

DEAR SIR,—Is it possible that your correspondent "P. T. L." is not aware that there are in Ceylon two species of jak : one a surface feeder, such as he describes, and another a deep feeder? I should have thought this fact was too universally known to need mention, but "P. T. L."'s remarks suggest the possibility, at least, of his not knowing it! The trees differ, not in the roots only, but in their ramification and fruit. The deep feeder is a much more compact and, in its early stages, a denser tree than the other, which is spreading and lax. The fruit of the former is also much more esteemed than that of the latter. I am not an advocate for *shade* for coffee, but *shelter* is often very desirable, and for that purpose the deep-feeding jak is valuable, and inflicts little injury on the coffee beneath. By-the-bye the present generation of planters do not seem to know that, originally, all coffee estates were opened with shelter belts. One, I remember, was opened in small fields of only a few acres each, and looked, at a distance, rather like a draught-board. I have still an old sketch of one of our principal coffee districts taken from a neighbouring peak, with many of the intersecting belts shown. At the time when the black bug attacked the estates, and overran the country, it was found that the pest lingered about the belts, even when it ha left the more open parts of the fields, and there was therefore a general clearance of the belts in consequence.

In the present crisis, when crops are so small, and the coffee trees so very shy of fruiting, any information of a reliable nature as to means of inducing the trees to bear, is of the highest value. Mr. W. D. Bosanquet's experiments are therefore most interesting, and he would confer a great obligation on his fellow planters, if he would inform them whether the excellent crop he has the good fortune to possess this year is confined to the manured portions of his estate; or whether it extends also to those which have not been subjected to his special treatment.

In this connexion, and as showing the importance of caution in drawing conclusions from experiments, I may mention that, a few months ago, I selected a dozen coffee plants that were covered with hemileia, for the purpose of experiment. Not, however, that I believe in any *cure* for hemileia, but simply in the interest of science. The plants, which were in pots, were removed to a spot favourable for the treatment to be tried. But, before commencing the treatment, it occurred to me to wait awhile, to see whether the change of locality, a very slight one, would have any effect on the disease. The result was that, after a few weeks, not a speck of the fungus was to be seen on the plants! Now, if the original intention had been at once carried out, the *cure* would almost certainly have been attributed to the treatment. G. W.

NUTMEGS.

28th July 1882.

DEAR SIR,—Referring to "Maligakanda"'s enquiry in your paper of 27th inst., respecting above, he will, I think, find that his non-bearing trees are male ones. *Myristica fragrans* is dioecious (staminate and pistillate flowers on different plants) and Simmonds speaks of there being "three sorts of nutmegs, namely, the male or *barren*, the royal, and the queen, the last being preferred." I expect your correspondent's best plan would be to coppice, say half of his unprofitable trees, and try grafting (by the crown or cleft graft), but "W. F." is better able to advise upon this point than yours truly, TASTE AND TRY.

P. S.—Your correspondent should read the *Tropical Agriculturist*, as in the February No., page 738, his question is anticipated and answered fully, in paragraph 12th of Lumsdaine's report.

RAPID GROWTH OF TEA AND OF THE PAPAW TREE IN PANWILA DISTRICT.

July 29th, 1882.

DEAR SIR,—It is a pleasure to read such good accounts about the sale and outturn of tea in Ceylon : will you allow me to say a few words as regards its rapid growth? A seedling planted on Maria estate about four years ago and allowed to grow up without topping, only having all primaries cut off from time to time up to four-and-a-half feet, was measured the other day and found to be twenty-one feet high,

the stem fifteen inches in circumference at 9 inches from the ground, and above the five feet height it is very bushy. This tree has been kept for seed and not been manured or had any extra care bestowed on it.—Yours faithfully, J. HOLLOWAY.

P. S.—Having a read a good deal about papaw trees of late in your *T. A.*, I had a fruit plucked the other day weighing two-and-a-half pounds!—J. H.

WHAT AILS OUR COFFEE TREES?

SIR,—There are, it appears, still amongst us some planters who believe that *Hemileia* has been the primary and potential cause of the fatal decline of our coffee crops during the last ten years; and, nothing daunted by past failures and discouragements, they are about to make renewed efforts to discover a *cure*.

Setting aside the question as to whether or not a cure for the pest be practicable, let us consider the larger, and far more important question, as to whether or not *Hemileia* has really been the primary cause of the sad loss of fruit-bearing power in our coffee trees. The evidences to the contrary seem to me to be both cumulative and conclusive.

Firstly. The first general disaster to our crops was in 1871, when the crop of the island fell suddenly to little more than half the previous average. Like its successors, this first misforune was universal, and affected coffee, more or less, in every district, of all ages, and regardless of soil, aspect, or any special conditions. As yet, however, *Hemiteia* was hardly known. It had been observed in only two or three districts, had visited only a very few estates, and had affected but a few groups of trees. Here then is clear proof that adverse conditions had *previously* set in; and that the fruit-bearing powers of our coffee trees were already seriously impaired before *Hemileia* could possibly have had any material or general influence.

Secondly. In the succeeding years, up to 1876, our coffee crops *alternated*; but there was no alternation in the progress of the pest, which spread steadily and with fatal rapidity. In 1876 the fungus may, I think safely, be said to have attained its utmost force. It had by that time, affected every coffee estate in the island, and I believe there was hardly a tree that had escaped its ravages. Moreover, it had increased in virulence as much as in the universality of of its attacks. Yet the crop of that year was one of the largest of the decade! A group of estates, I visited in February of that year, were almost leafless. The fields were brown, and the trees a mass of bare sticks. They were suffering, in fact, from the fiercest attack of *Hemileia* it has ever been my misfortune to behold on so large scale, and they presented a most desolate appearance. Yet, notwithstanding this terrible attack, immediately preceding the blossoming season, these estates gave the best crop that year that they had given since 1870! On the same journey, and only a few days later, I visited another estate which was comparatively free from the fungus, a picture of luxuriance, and with every apparent promise of crop. But this estate gave, in that same year, less than a tenth of its ordinary crop, a failure exceeding any I had, up to that time, ever witnessed! Of such discrepancies my experience furnishes numerous instances. Only last year, on remarking what a fine crop there was upon a small field I had in view, the manager of the estate reminded me that on a very recent visit, I had remarked on the virulence of the fungus on that very spot. In citing these cases, I shall not, of course, be understood to attribute the good crops to the *Hemileia*, nor the failure to its absence! But I maintain that such discrepancies prove, beyond doubt, a want of that sympathy between the ravages of the pest, and the unfruitfulness of our coffee trees, which would necessarily exist between *cause* and *effect*. There is, in fact, no such correspondence between the attacks of leaf-disease and the failure of crop as a mutual dependence would imply.

Thirdly. Coffee has not been the only product of the soil to suffer. Even in Ceylon the cereal crops, which have had no leaf-disease, have suffered almost as much as coffee, and from about the same date. From the same fatal year, 1871, disastrous of far greater magnitude than any we have suffered, and affecting agriculture over the whole face of the globe, may be dated. India has suffered dreadful famines, successively, in Bengal, Madras, Bombay, the N. W. provinces, and Cashmere. China has had to endure a famine yet more intense and of longer duration. Persia, Turkey, and the South of Russia have endured a similar fate in varying degrees. Europe notwithstanding its teeming capital, and all its resources of science and skill, has had to bear terrible agricultural disasters, and their miserable consequences. Even in Great Britain, we learn from Mr. Caird, the highest authority in such matters, that there has been but one good crop of cereals, that of 1874, since 1871. The fruit crops of the U. S. of America have failed so persistently during the same period that the Board of Agricultural lately reported that the art of fruit culture seemed to be lost!

It would seem, therefore, that some wider influence than that of *Hemileia* has been in operation during the period of our depression; not in Ceylon only, but over the whole world. And it appears also that elsewhere, as well as in Ceylon specific pests have followed in the wake of that more general influence, and have attacked, not coffee only, but other agricultural products.

Fourthly. Evidences that something affecting the fruit-bearing power and stamina of our coffee trees had preceded and invited the attack of *Hemileia* are strong and consistent. It is a characteristic of the whole family of fungi that they prey upon organisms bordering on a state of decay, and upon such as are suffering under conditions uncongenial to their habit. Of 200 species of fungi that infest the British Oak, only 6 attack the growing tissues! All the rest await the autumnal decline of vegetative power, and prey upon the dead or dying members. The decompos ition of organic substances is almost always accom panied by, and has therefore become almost synonym ous with, fungoid agencies, such as ferments, &c., &c. mark, then, how well this view of the advent of *Hemileia* agrees with the fact that sickly and suffering coffee trees are subject to its first and worst attacks. Of such trees, indeed, *none* escape. Though healthy and luxuriant trees around them and in actual contract with them are scarcely injured, these are nearly killed! Nor have such trees any *respite*, for when the fungus disappears for a time from the stronger trees, it still clings with fatal force to these miserables.

The foregoing arguments are based on facts which are well-known, and which have, no doubt, been carefully considered by many of my fellow planters who, nevertheless, revert to the popular idea that leaf disease has been the cause of all our misfortunes, simply because there is no other cause *apparent*! It is natural to assume that there must be a *recognisable* cause for a change so remarkable and so widespread as that we have witnessed in our coffee; and so we blame the *Hemileia* because it is the only one we can *see*! And this would be a reasonable conclusion if we had all the forces of nature within our ken. If all possible causes of infertility, and all the conditions necessary to fruit-bearing, were within the scope of our knowledge, we might conclude, if no other cause were *evident*, the *Hemileia must* be the true cause. But our misfortune is that, so far from our knowing *all* the laws and conditions of nature

operations, we know but *few*, and even those few very imperfectly. The real cause from which we suffer may probably be one of whose nature we have no more idea than a deaf-born could have of sound! It may therefore, elude our most persevering and painstaking research; but we should not improve our chance of asertaining it by starting on a wrong tack! It is not consolatory to feel that we are in search of something that may prove to be beyond our reach; but it may save us from wasting our time and substance in efforts in a wrong direction. The sooner, in fact, that we cease to regard *Hemileia* as the prime cause of the unfruitfulness of our coffee trees, and recognize it in its true light, as a consequence which fearfully aggravates the evils we suffer from some *remoter and possibly inscrutable condition*, the sooner shall we cease to court disappointment by following wrong paths.

It is a wise decision on the part of our Government to decline to offer a reward for the cure of leaf disease, as it will prevent many from diverting their thoughts from their more legitimate business, to the pursuit of an *ignis fatuus*. The commission lately appointed by the French Government to consider the merits of a host of claims to the prize offered for a cure for Phylloxera, attest, in terms which I regret I cannot quote as the precise words escape my memory, the *mischievous* effect which that offer of a prize has produced, without any compensating useful result.

Our hope lies in careful and persevering attention to those strange and accountable exceptions which are to be found in every district, and on almost every estate, where trees, or groups of trees, or even whole fields of coffee, differing in no other apparent manner from those immediately around them, are nevertheless bearing abundant crop, whilst their neighbours are utterly barren! However universal and inscrutable may be the operative cause of infertility, these exceptional trees or spots have been favoured by some counteracting influence, potent enough to prevail over that cause. Would to God that we might discover this beneficent influence, and restore those conditions of fertility and health, the want of which has brought this pest upon our enterprise!

So long, however, as our trees lack that vital stamina, or essential condition of fruitfulness, be it what it may the removal of *Hemileia*, even if that were possible, would leave us still open to renewed attack. Even if we were fortunate enough to discover a cure, and to obtain the co-operation of every owner of a coffee tree in the Island, to carry out, by combined action, the total destruction of the fungus, it would find us out again, as it did before; unless those antecedent conditions which invited its original attack were first removed, or counteracted. As rapidly as it originally travelled from Sumatra to Ceylon and South India, so rapidly would it return. We must go to the root of the mischief! Our prospect of success may be remote, and our discouragements great, but it is more profitable to seek the substance, than to pursue its shadow.—W. in the Ceylon "Times."

LOSS OF NITRATES IN THE SOIL.

The effect on the planting enterprize of Ceylon: altogether one million sterling lost per annum through causes more or less remediable.

29th July 1882.

DEAR SIR,—I am glad to notice that you have found space in your July number of the *Tropical Agriculturist* for Mr. Warington's lecture on "the production and loss of nitrates in the soil," for after its careful reperusal I am more than ever forced into the belief that the subject merits the very serious attention of agriculturists, of all shades and denominations, everywhere, but particularly in the tropics, owing to the (unfortunately) more favourable climatic conditions prevailing, to the nitrification of any nitrogen present in the soil. Here, at all elevations, though more particularly in very hot, moist localities, we are evidently thus especially subjected to the rapid loss of our existing stock, at once on the land being cleared, unless immediate precautions are taken to conserve and reconvert the nitrates, as they become formed again into nitrogen. This, if Mr. Warington's deductions are correct; and can they be doubted? I am even inclined to say that the rapidity with which tracts of land, especially at the lower elevations, have both in this country and elsewhere become deprived of their fertility affords conclusively substantiative proof, and that the impoverishment caused by chenaing which we have hitherto most of us, I fancy, attributed solely to the abstraction of fertilizing matter by the crops removed, is to no small extent due to the ruinous loss of nitrogen caused by nitrification. Or I would say this: that if a piece of land of however good quality be cleared and deprived of vegetation of any sort, it will gradually become *almost* sterile with a rapidity proportionate to the amount of nitrogen present in it originally and the climatic conditions—favourable or otherwise—to the process of nitrification. I have used the expression *almost* sterile, as I believe it is correct to say that the rain falling, whilst it washes out the nitrates that have become formed, at the same time gives up to the soil it penetrates a certain amount of fresh nitrogen in the form of ammonia; and though insufficient alone for the purpose of profitable cultivation, as the other plant constituents that may exist remain we are told ever present (unless removed from the land by crops or wash), a certain low state of fertility, it is but reasonable to suppose, will always be maintained. Or is there any reason adverse to the conclusion that it could be either kept up, or restored to its original standard by artificially supplying the waste of nitrogen, in due proportion, as it occurred, or at any time subsequently? Now the question I would ask (that is if the subject be considered deserving of the importance I am induced to attach to it, on the strength of Mr. Warington's remarks, and I shall be in particular glad if Mr. Wall chances to think so, as we may be certain then of its being properly handled, and the many *pros* and *cons* fairly thought out and explained):—have we not, especially of late years, maintained a system of cultivation, which we have come to think near to perfection, at an almost appalling cost in the loss of nitrogen (more particularly, unfortunately, under the prevalent method, of at the outset resorting to, more or less close and deep draining), and this over vast areas of land throughout the country? For the admission seems to me unavoidable that under it the whole extent has at the commencement had virtually to remain under *bare fallow*, and subject to periodical heavy falls of rain for the space of two good years. And I would further ask: After the coffee may be considered to have fully occupied the ground, does reason or proof exist to shew that the trees are capable of taking up all the nitrates as they become formed? If not, is it too much to infer that, on a perfectly clean kept—and more particularly, if well drained—coffee estate, the *surplus* nitrates are on the setting in of the monsoon rains rapidly washed out, and carried off, first by drain to stream, then from stream to river, and ultimately to sea: unless some more than ordinary intelligent native has, where possible, had the forethought to pass the water, as it came from *drain* or *stream* through his paddy field, and that thus a perpetual loss of nitrogen (whether it be large or small is a point for consideration!) is incessantly going on, apart from crop drafts on it?

Strong arguments I know can be addnced nnder other headings in favour of the present syst-m and as to its being the most, if not the only, efficient one. Under the item of draining however—as regards the chief point in its favour, viz., the prevention of wash—I am inclined now, from an experiment under trial, to believe that this might have been, and can be, as effectually checked by a system of terracing (not unsimilar to the Sinhalese method of terracing their hillside paddy fields) at a somewhat greater though not *prohibitive* outlay. And then as regards clean weeding. How would it do on young clearings upcountry, rather than leave the ground bare during the rains, to grow thinly-planted crops of sugar beet (beet being a crop highly spoken of for the purpose intended)? If it be not rich in nitrogen, extract the sugar, and return the refuse, either in the form of cattle manure, or directly, or after killing the roots, to allow them to rot, as they stand? In the lowcountry a crop of mustard, to be dug in and repeated at intervals, might meet Mr. Warington's advice, and I am inclined to fancy might prove an effectual check on white ants. At least a friend who has studied agriculture at home mentioned the plan as effectual in the case of wire-worm—here now the pests have taken to cutting down the young nutmeg plants. These, however, are not the only points for or against the existing system. But the fact (on Mr. Warington's shewing) remains, as far as I can make it out that it can only be carried on without some modification's or improvements at an alarming loss of nitrogen.

We are told that at a temperature of 98° nitrification takes place *ten times* more rapidly than at 57°; that "the average of the two sizes of drain gauged 20" and 60" deep shewed that during 5 years they had in the one case 44·8 lb. of nitrogen draining through the soil, and in the other case 42 6 lb."; that nitrates form rapidly on bare fallow, and that when formed, on wet weather setting in, they are rapidly washed into the drains and carried off, or, deep down into the soil that he (Mr. Warington) believed that a part of the present agricultural depression was owing to the extremety wet winters of the past few years, lowering the condition of the soil by washing out extraordinary amounts of nitrates.

Now in consideration of our everywhere higher temperature, and the enormous excess of rain falling during the monsoons, it can hardly be an exaggeration to *assume* twice the home loss, as occurring, at least, during the first two years of a clearing, if left under bare fallow, as usual at present, and consequently a sufficient quantity of nitrogen is allowed meanwhile to escape to support a crop of 120 bushels of wheat —or probably over two tons of coffee—unless it can be shewn that coffee consumes proportionately more nitrogen than wheat; when, if this be so, its loss is obviously of still more serious import!

And it is not only to coffee that this seems to me equally to apply but to almost every new product as yet under trial in the country.

The fact that, if not drained off the land, the surplus nitrates get washed deep down into it, I think points to the reason why tea is found to be a so particularly lasting cultivation, and why it continues to improve in yield rather than diminish for several consecutive years without manure, and why too it (if more slowly at first) eventually attains to full perfection, in many places, on abandoned land: also why we may anticipate that Liberian coffee will prove a more lasting tree than C. arabica, and certainly less dependent on extraneous supplies of nitrogen. They are both, the tea especially, deeper rooted plants, and, as they grow old, their roots search out the nitrates that have been washed down to a depth completely beyond the reach of the roots of the former, or by reason of their greater strength break into hard soils these could not possibly penetrate. Tea too, as it has often before been pointed out, may be presumed to perform a much more powerful part in draining the land, and (vide Mr. W.) may be regarded as exercising conservative influence, not merely by reason of the nitrates taken up, but that, by relieving the soil of an excess of moisture, a check is placed on their too rapid formation. Mr. Warington's remarks seem also to afford explanation on a point that has often puzzled me, viz., why in the dryer sections of the island (at least those that are or have been under forest) at all elevations, the soil is as a rule far richer than elsewhere. The reason, I would now suppose, is that the fallen leaves decay more slowly, and that with less heavy rain the trees have time granted them to absorb a majority of the nitrates formed, to be again returned in the form of insoluble nitrogen at next fall of leaf; whereas, wherever periods of protracted heavy downpour occur, a vast quantity of the nitrates must surely be carried away even on the heaviest forest land, though not to the same ruinous extent, of course, as on bare fallow, but that nothing short of a close growing crop such as wheat or grass fallowed entirely prevents it. Did the same quantity of rain, be it almost however great, fall evenly and gently throughout the year, so that the nitrates were brought gradually to the roots as they became formed, instead of as in many parts of the island now (owing to the clearing, I suppose, of *extents* of forests!) in heavy plumps alternating with spells of dry weather (washing *off*, instead of *into*, the elements of fertility) it would be quite a different matter. I remember well a very old Badulla planter, some years ago, too, contrasting seasons present and past. He said that in olden days, in many parts of Ceylon, there was almost an incessant light drizzle and mist occurring, so that you rarely saw the sun for any continuous length of time. And I think I remember too Mr. Shand once telling me that in Rakwana they used formerly to experience the greatest difficulty in getting their crops dried for a similar reason.

The conclusion forced on my mind is that, to take full advantage of *nature's gifts*, it is necessary to devise means:—1st, to pass every drop of rain water that falls *through* the soil, and thus clean rob it of all its riches: 2nd, to place an effectual check on the nitrates as they are formed being wholly or partially washed away or beyond the reach of the plants. That as regards the application of nitrogenous manures, they should rather be supplied often and in quantities sufficient only to meet the more immediate requirements of the trees and in proportion to the crop set that may be required to be supported; and that to apply such manures as castor cake and other poonacs in over big doses can only result in great waste.

It is out of no desire to run down the present *modus operandi* of estate working that I venture the above queries, but rather in the hopes that they may give rise to suggestions likely to counteract, if possible, any existing defects. Draining is undoubtedly a desirable work, if only means can be devised to conserve the nitrates, and further, to pass the rainwater *through* the soil before it reaches the drains. And so as to clean weeding: if by other means than allowing the weeds to grow (and be hacked down from time to time as in olden day here, or, as at present, I believe, in some parts of India, sickled!) the nitrates can be conserved. What I would be inclined to say is *add to* rather than *alter* the present system.

If the losses that have been caused in Ceylon—by wash, waste by nitrification, short labor and consequent fall of crop, white weed, thieving cart contractors, and the want of railway communication not only in one

but in various directions, the medical ordinance, and as a climax by leaf-disease—since the stumps were removed, and the *first cleared* coffee estate ploughed by elephants could be totalled up, I fancy it would amount to an average sum not far under the round million sterling annually. Much of this loss has of course been unavoidable, but, perhaps, it is worth pondering over with a view to the future. And as to this; if 25 million pounds more or less, have been lost to the planting interests during the present century. I firmly believe as many, fully, will yet be realized before its close, though there are only 18 years more to run.

Another query suggests itself. We are told: "Nitrates are produced as part of the living functions of a very low order of living organisms, bacteria, present in the soil."

Now is this bacteria identical with the organism similarly named, and to the presence of which in our blood, fevers and malarias are attributed? If so—though the germs only, I suppose, can be borne by and imbibed from the atmosphere—it would seem certain that a vast quantity of the fully-developed animalcule must be present in the water—however clear and bright it may look out of any stream or spring draining a new clearing. And may not this account for the fever always occurring with greater or less severity at low elevations, just at first? May not a reason be found here too why malarias of the more severe types than usual exist, and hang on long, in localities where the land is especially rich—and should I add?—as nitrates seem to be an essential part of the bacterias—is it not probable that the exemption from malaria at high elevations is to be attributed to the lower temperature? That hence nitrification taking place less rapidly, neither they nor their spores are at any one time originated in harmful quantity? X.

MINCING LANE CRITICS AND CEYLON TEA.

Central Province, 1st August 1882.

DEAR SIR,—With reference to your article headed "Tea in Ceylon" and the extract from a broker's report which you quote, may I be allowed to point out that, supreme as Mincing Lane authorities undeniably are in such questions as the relative selling value of teas, and the prospects of the market, they are not equally infallible when, overstepping these boundaries, they proceed to enlighten their customers with their views on the subject of manufacture. Gentlemen who take upon themselves to tell us that we are ignorant of the first principles of manufacture should be sure, before making such a statement, that they are themselves acquainted with these principles. Now, when Messrs. Gow and Wilson tell us, as they do by implication, that, because the teamaker does not turn out a "thick, malty tea," he fails to do so from "neglect of the first principles of manufacture," they commit a ludicrous error of a kind which recalls to memory the time-honoured story of the coffee proprietor in England, who is said to have instructed his superintendent to grow nothing but peaberry. The teamaker may, by certain variations in his mode of manufacture, make his tea a little more, or a little less, deep in colour and full in flavor, but it is not possible to make a "thick malty liquor" from leaf which yields tea of a "thin but fine and delicate flavor." For such a radical change (if it were possible) we must look to cultivation rather than to manufacture. But even more absurd is the solemn injunction to make a "sound, useful tea, not coarsely plucked, *however*." I italicize the *however*, because though it may not be known to these gentlemen, it is nevertheless true, that "*sound, useful tea, thick, malty flavour*, and *suitable for mixing with China, sorts*" could never, by any process of manufacture be made from coarse leaf. I lately observed in another Mincing Lane gentleman's report, that certain Ceylon tea had a smoky flavour, which he gravely proceeded to state was to be attributed to incorrect fermentation. My brother teamakers will appreciate the joke. It is really time that some of these gentlemen should cease to be funny, and should turn their attention to elucidating the strange fact, well known to some of us, and of which I, for one, possess proofs, that better prices can be obtained from provincial dealers than are procurable in "the Lane."

It is equally incorrect to refer to prices procured for Ceylon tea as unsatisfactory. Some may be so, but the figures fetched by some five or six marks I could name, compare favorably with average Indian prices. On perusing a sale list, it will be found that the very high prices, viz., those from 2s upwards, are few and far between, and form but a small proportion of the bulk. And it is quite possible that our average priced teas may be more remunerative to the producer than some of the higher priced rivals.

I enclose my card.—I am, dear sir, yours truly,

TEAMAKER.

THE COFFEE CROPS AND UNFAVOURABLE SEASONS.

Waverley, Agrapatana, 2nd August 1882.

DEAR SIR,—Mr. John Hamilton is perfectly correct when he writes you (31st ultimo) that our blossoming seasons for the past four years have been bad, and hence a reason in a great measure for our crops failing. In 1878 we had 31 days *in succession, without a cloud*, and thereafter a shower gave us a blossom, from which was picked on a 25-acre field on Chrystler's Farm 276 cwt., or 11 cwt. (over) per acre, while the whole estate gave over 5 cwt. per acre, with one-third of the acreage not in bearing. The adjoining estate, Yuillefield, gave over 7 cwt. per acre. These estates in one or all of the years since 1878 have looked as well, if not better, but I do not suppose they have given one-fifth of the crop they gave then, simply because we have not had a succession of scorching, dry days, during our blossoming seasons, such as we had in February and March 1878.—I am, yours faithfully,

ROBT. C. BOWIE.

SPHAGNUM MOSS.

DEAR SIR,—I have much pleasure in replying to Mr. Nock's inquiry concerning the localities where varieties of this moss are found. Several of the places where I have seen it growing are now cultivated lands. I first found a variety in wet marshy grassy places in the wilds of Laggala and Nitre Cave; also in similar spots in Ambagamuwa, Bogawantalawa and Maskeliya. I regret I have not got the specimens I collected by the Maskeliya-ganga.

Some years ago I saw the same moss by the old road from Dimbula to Nuwara Eliya, and on the same journey between Nuwara Eliya and Kandapola. Very I intend spending a day in search of some old favourites in the jungles by Nuwara Eliya, where I may meet Mr. Nock.—Yours, OLD BOTANIC BOY.

TEA: CLOSE PLANTING FOR OLD CLEARINGS.

DEAR SIR,—Mr. C. Shand's hints are in season. At this moment there are doubtless many coffee estates in the island being metamorphosed into tea gardens, and a word in season may not be amiss as regards distances in planting. We look to the example and experience of India in the great enterprize now dawning in Ceylon: and from all we learn about the dimensions attained by the indigenous Assam and the high class hybrid plants in India, we expect to see plants of enormous proportions here. We read in

the local papers of the height attained by trees in this place and the yield per acre in that; and with that belief which we have in the soil and climate of Ceylon we may readily jump to the conclusion that we must do a great deal better in Ceylon than in India. There are districts and estates in Ceylon, beyond doubt, that may realize the most sanguine hopes of the enthusiast. But in planting up an old estate one must be careful not to overrate the fertility of his soil, or the suitableness of his climate. Here in Ceylon many of us have accepted 4 × 4 as a fair distance to adopt in planting tea. It may be open to question how far it would be safe to accept this as a fair distance for old clearings, steep slopes, and high elevations. For certain and speedy returns it may, therefore, be advisable to adopt a closer system of planting on old clearings. Even on the same clearing the difference of growth is apparent between the bushes on flat, or gently undulating land, and those on hillsides, pointing clearly to the necessity for closer planting on certain lands. Apart from the consideration of wash, which does not exist in any great measure in Ceylon clearings, there are advantages which cannot be overlooked. For one thing the tangible advantage of speedy returns. Indeed Colonel Money himself, in spite of the general rules laid down, points out the advantage of close planting. At page 44, third edition, he speaks of slopes and adds :—"The closer the lines to each other and the closer the plants in the lines to each other, in short, the more thickly the ground on slopes is planted the less will be the wash, for stems and roots retain the soil in its place *and the more there are the greater the advantage.*"* Again at page 59 he repeats himself with a modification:—"Plant as close as you will in the lines, but give each plant its own home." Then at page 70, he maintains :—"Where manure is obtainable and the soil can be kept up to a rich state by yearly applications a garden can scarcely be planted too close. I see no objection to trees touching each other in the lines. On considerable slopes, to prevent wash of soil the plants should be placed as close as possible, say 3½ feet between and 2 feet in the lines. A closely planted garden will grow less weeds than a widely planted one, and will consequently be cheaper to work. As the expenditure in a garden is in direct proportion to the area, and the yield in direct proportion to the number of plants (always supposing there is power enough in the soil to support them), it follows that a closely planted garden *must* be very much more profitable than the reverse."

His advice as regards "flat land and for hybrid, *if high class*" is to plant 4 × 3½ or 4½ × 4. What then should be the distance, in planting up old coffee is a question, the answer to which must depend on soil, elevation, lay of land, &c.

All the same for speedy returns the writer would advocate close planting. The Ceylon planter would soon enough know how to keep the soil in a state of fertility, to support the trees when the estate proves a paying concern.—Yours truly, PEKOE TIPS.

P. S.—Since writing the above I have read the advice of the Darjiling correspondent recommending the sowing of a few seeds under existing bushes to make them many-stemmed.

WHAT AILS OUR COFFEE TREES?

DEAR SIR,—As you have paid my letter the compliment of devoting a leader to a critique thereon, I will ask you for a little space by way of rejoinder.

Let me premise by pointing out that the letter did not profess to answer the question as to what ails our coffee, but was intended solely to prove that *hemileia* was *not the primary* cause of the universal decline of the fruit-bearing power of our coffee trees. In that connexion I submit that no other cause came logically within the scope of the argument. Though fully sensible of the ravages of *grub*—and also that *seasons* have been abnormal—I submit that these terrible factors of our depression had no connexion whatever with the argument with which my letter was exclusively concerned.

Of the many causes to which our misfortune has, at one time or other, been attributed by your correspondents and others, there is not one, I believe, which answers the essential conditions of a *primary* cause of the universal effect we all deplore; nor am I hopeful of any immediate discovery of that cause: but there is reason to hope that, even though it remain a mystery, we may discover the *counteracting* influences or conditions to which we are indebted for those strange and exceptional cases of fertility which are to be found in the very midst of surrounding barrenness.

My letter under review was intended as a contribution towards a thorough analytical and critical investigation of each of those causes which have met with any general acceptance. And by proceeding logically, step by step, disposing of each in turn, we may hope to direct our efforts to useful ends, and not waste them in wrong directions.

Leaf-disease was the first to claim attention, as being the most universal and also the most mischievous in its efforts, of all those secondary agencies which have followed in the train of that remoter, mysterious and unseen influence we would fain know, or learn to counteract. *Grub*, abnormal seasons, a "too exclusive devotion to one product," and other causes which have contributed to the "terrible change" in the fruit-bearing power of our coffee, will need special notice, but each separately and in turn, and not all at once.

Considering the thorough knowledge you possess of the views of the whole planting community, and the strong interest you have always taken in the discussion of agricultural topics, the views you advance may be regarded as almost an embodiment of those most generally held by planters, and may be dealt with accordingly.

Confining myself, for the present, to such of your remarks as bear on leaf-disease, and deferring the rest to a future occasion: your argument against the existence of a "predisposing condition of the coffee trees" seems to me to favour my view and to *imply* the existence of such a condition. You say that "the fungus was *latent* on the allied trees of our jungles," an assumption which seems to me to imply that it remained in a latent state *until* some favouring condition supervened to bring it into active play. Your words clearly regard the *hemileia* as a secondary factor, brought out of its latent condition of abeyance into terrible activity by some *preceding* influence. It is this influence, this primary motive power, of which we are in search! Coffee had covered large areas of land for 30 years, surrounded by the indigenous vegetation in which, you say, the fungus was all along latent; but it so remained until stimulated into fearful activity by some newly acquired condition of the trees. The existence of this *primary* cause is what I contend for, its nature, or something to counteract its ruinous influences, is what we want to discover.

The secondary character of black bug, which you regard as a parallel case to *hemileia* has been established in our experience. This pest was known in the country long before it took its sudden devastating tour of the coffee districts, and threatened to extinguish the enterprize. It had long disfigured some few of our garden shrubs, but was powerless over our

* The italics are mine.

coffee fields, until favouring conditions attracted it with electric rapidity over the whole existing area of coffee! Whatever may have been the influence or condition which gave it such fatal force, it passed away after a short reign, the bug retired into its previous inactivity, and so remains to this day. Its attack followed a long period of rain, and was attributed by many planters of the time to "wet feet." If this view be correct, we may hope that modern drainage may save us from renewed attack. But, whatever may have been the favouring conditions which first introduced the attack, I am satisfied that, if they were now to re-appear, the fire of our old enemy would be relighted, and the sooty foe would return, and would remain as long as those conditions prevailed. In like manner, were *hemileia* to be for a while wholly extirpated by some remedial agency, whilst the conditions still existed which first attracted it from its latent state, it would again leap forth from its lurking places, and resume its devastating work. These pests are not freaks of nature or chance visitations, but the workings of her immutable laws. As the black bug disappeared without artificial agency, solely by changed conditions of an unseen and unknown nature, so will *hemileia* disappear; but not until that primary cause which first brought it out of its latest state shall have ceased its influence. In other words, it will continue obedient to law. Would that we could discover that law; or learn at the least how to take the hints that nature gives us in counteracting its effects. The secret is embosomed in those spots where fertility still stands in strange contrast to surrounding fruitlessness. W.

COFFEE UNDER HIGH CULTIVATION IN DIMBULA: THE COST AND RESULTS.

Yoxford, Dimbula, August 8th, 1882.

DEAR SIR,—In reply to "G. W."'s question in your issue of the 1st instant, it is undoubtedly the case that only on the manured fields of the estate is the coffee now bearing a first-rate crop. There are patches, however, which, owing to exceptionally favourable circumstances, have a very good show of crop, though unmanured. The main difference between the manured and unmanured fields is that the former are bearing evenly, while the latter are patchy. On the older coffee, which is more exhausted by previous cropping, I find that one application of artificial manure by itself is hardly sufficient to restore the trees to good heart, but that, if the artificial is bulked with a little compost, the desired result appears to be at once attained.

As to your question of cost, I shall be in a better position to give you exact figures next year, but, at present, I can say that coffee manured last year at a cost of R50 an acre is this year bearing from 7 to 8 cwt.

Referring to a previous letter from your correspondent "G. W.," criticizing my experiments and comparing some of his own, I would first observe in reply, that, in accurate scientific experiment, *appearances* count for little; and secondly that, if your correspondent had given the subject practical consideration, he would never have suggested plots of such a size as 300 trees in length by 10 in breadth. Further, in support of my method of experiment in small plots, I will quote from the last report of the Aberdeenshire Agricultural Association, in which the following sentences occur:—"Experience of plots of various sizes had led to distrust of results from large plots, and to the adoption of plots 34 ft. 7 in. by 11 ft. 3 in., or 1-112th of an acre: this size is highly recommended both for insuring equality of soil, conditions of cultivation, and accuracy of work."

In conclusion, let me disclaim all pretensions to knowing all about manuring. I consider that, at present, I am but at the commencement of the enquiry, and only through the cumulative experience of years of experiment do I hope ultimately to arrive at something like definite conclusions. My experiments have, however, already taught me much of which I was previously ignorant, and, if others would but make a few similar trials, their experience, like my own, would soon lead them, each one for his own estate, to the adoption of the most profitable system of cultivation.—I remain, dear sir, yours faithfully,

WM. D. BOSANQUET.

[Hear, hear.—ED.]

TEA.—The latest reports from the tea-growing districts continue favourable, and the outturn from most gardens up to date has been larger than the estimates.—*Pioneer.*

AS VANILLA beans were never so cheap as at the present time it is probable that those who are fond of icecream will this year learn the true flavor of vanilla. Heretofore all sorts of abominable mixtures of tonka and other flavorings have been palmed off on manufacturers of ice cream as true extract of vanilla, and the consumers, not being a judge, and perhaps never having tasted the delicately pleasant flavour of the genuine article, were satisfied. There is now no excuse for adulteration when prime beans can be purchased for one-third the price asked three years ago.—*Oil and Drug News.*

RECENT COFFEE CROPS AND THE SEASONS.—We attract attention on page 247 to the important facts related by Mr. Robt. C. Bowie, as coming within his own experience in the Dimbula district and bearing upon this important question of the seasonal influence on recent coffee crops. So far as the higher districts are concerned, it is quite certain that the blossoming season—January to March inclusive—*cannot be too dry*; and, after such a south-west monsoon as the current one, we think there is good reason to anticipate a drier spring in 1883 than has been experienced since 1878.

BUDDING VS. GRAFTING:—MASKELIYA, 25th July.—Rain and rivers almost impassable in this month's weather account; crops small, but no smaller than our neighbours'. On the whole the valley should send away as much as last year. Coffee looking well: where not touched by wind and very little leaf-disease and that on shuck trees only. Cinchona doing well: looks just now a little knocked about by the wind. "Budding" will whip "grafting" yet. All you want is two gunwad punches, one a size larger than the other and a string. The business is simple: with the larger punch, punch out a piece of the bark to the cambium of Ledgeriana or good hybrid with a little shoot or eye in it; with the smaller tool punch out a piece of the bark of succirubra. Then put the Ledgeriana or hybrid into its place at once and tie with a piece of worsted or soft string, a little clay or grafting wax round the circle, and I'll lay a penny on *the bed*. The punches should be of different sizes, as the (bark) piece punched contracts. Mauritius grass makes a good covering for shaved cinchona; the damp instead of injuring does good. Young trees shaved in March 2½ years old and covered with it have renewed well. The new bark is thicker than the original, and on some of them the Mauritius grass has grown into a matted mass. It does not take long for a cooly to remove it to a ravine out of the coffee afterwards. Mana grass is preferable, when procurable. "Poor Ramasamy" begging for work. Too many in the district; not for the work that is required to be done, but for the amount of money to do it. Grub beginning to eat the roots of cinchona as well as coffee. I do not believe there is a coffee tree on our flats that has not had 1 dozen to 1½ dozen grub eating away at his roots. Some folk say they have no grub; dig round a tree and look.

TOBACCO.—The *Java Bode* of the 3rd June calls attention to the great falling-off in tobacco cultivation in Java, formerly so flourishing there, as evidenced by the fact that lately, in the eastern portion of that island, three estates were sold collectively for the trifling sum of 5,700 guilders, while only three years ago a brick tobacco shed on one of them cost 400,000 guilders. The decline in oultivation is ascribed to the low prices of tobacco in Europe.—*Singapore Times.*

NEW REMEDIES.—Mr. B. Walker, of Derby, in writing to the *Lancet* (February 18, p. 296), speaks very highly of the value of calcium sulphide in boils and skin diseases, and remarks :—"It is destined to play a most important part as the great germicidal remedy. It is thus invaluable in croup and diphtheria. Dr. A. Fontaine, of Bar-sur-Seine, who has treated four hundred of these cases, finds the mortality reduced from 16 to about 6 per cent. This substance is very difficult of administration and does not keep well. He recommends, therefore, the tasteless grauules containing $\frac{1}{6}$ of a grain. One of these is given every half-hour or hour until the vapour of sulphuretted hydrogeu is given off from the skin and lungs and then every three hours only." A statement of Dr. W. H. Lambert, in the same journal, that he had cured a case of that frightfully infectious and fatal disease, puerperal fever, by four minim doses of tincture of aconite, shows that an antidote to the poison which accompanies germs may be quite as effectual as one that merely destroys bacteria. The revival of the use of another ancient medicine shows that Isaiah's remedy for Hezekiah's boil deserves more attention than it has received in modern days. Professor Billroth has found that in a case of cancer of the breast, which was so excessively foul smelling that all his deodorizers failed, the application of a poultice made of dried figs entirely freed it from odour. Professor Bouchut also finds, as the result of his experiments, that the milky juice of the fig tree possesses a digestive power.—*Pharmaceutical Journal.*

TEA : ADVICE AS TO CULTIVATION.—A correspondent sends the following to the *Darjeeling News* :—Let all the bushes be many stemmed ; a great many are so now. Let the single stemmed bushes be converted into many stemmed by sowing a few seeds under such bushes. Many stemmed bushes admit of sundry of the stems being cut down to the ground year by year, from which new shoots arise, and this thinning out of the bush can be done without reducing its yield, while permitting of its being entirely renewed in four or five years by which time the bush will be far larger and healthier than when first taken in hand. All the pruniugs should be collected n heaps and reduced to ashes. It is anticipated thate hy the numbers of the pest "red spider" being thus greatly reduced and by the increased energy of th plant enabling it to overcome the attacks of its enemies whether spider, "blister blight" or lichen, and fungi on the stems, gradually all these enemies to the welfare of the plant and planter may be exterminated. The writer also states that in another part of India, where "red spider" is, fortunately, nnknown, he has during the past six years, by gradual renewing ten years old, neglected. stunted, scrubby bushes, raised the yield from three maunds tea to eight maunds maximum and six maunds minimum per acre. Most planters bury the prunings round the roots. We well recollect suggesting to a very old and experienced planter, (with some diffideuce) that burning might be the safest, and that probably there would not be much loss in manure value. But he quite ridiculed the idea. [In recommending many-stemmed bushes, the correspondent must have the Chinese plant in view. The objections to burning twigs whether on tea or coffee estates are first the expeuse, second the danger of conflagration.—ED.]

GOOD PRICES FOR COORG COFFEE.—A gentleman writing from Amutty, Coorg, on the 22nd instant, says :—I do not know if it is of any interest to your paper to hear of good prices realized in these depressed times of coffee from here, but I can send you an account sale of this estate's last season's crop averaging 95s 2d for 23 tons *including* triage, all sound.

GHEE.—A short time ago the attention of the Agricultural Department of the Government of India was directed to the manufacture of *ghee* in Australia for shipment to ports in India. It was then stated that the quantity of butter available in parts of the colony was so great that ghee could be manufactured and laid down at any Indian port at a very low price. We hear that the subject has been submitted for the opinion of the Board of Revenue and that the views of the different collectors have been called for. Ghee is manufactured in very large quantities in the interior of the districts and supplies are continually shipped to Calcutta and Ceylon. Last month about R3,000 worth ghee were shipped at Madras for Calcutta and Colombo.—*Madras Standard.*

THE PRESERVATION OF WOOD.—A new wood-preserving process has been invented in France by M. Jacques. He first impregnates the timber thoroughly with a simple solution of soap, mixed with an acid—preferably phenic acid. This causes the fermentation, in a few days, within the wood, of a fatty acid, which is insoluble in water, and impregnates the remotest fibres. The reaction of the acid on the soap does not take place until a portion of the water has evaporated. It is claimed that more perfect impregnation can be had in this way than with creosote, and there is no danger of the washing out of the preservative from the exposed surfaces, as when sulphate of copper is used. The Government Commission on technical railroad operation in France is said to favour this process.—*Metal Worker.*

WEST INDIAN FRUIT—GLUT OF RED BANANAS.—The schooner "Mary F. Pike," Capt. Good, arrived here from Baracoa this week with a large cargo of red bananas and several thousand coconuts. Last week within 24 hours, thirteen cargoes of red bananas, in all 34,000 bunches arrived in New York. It is expected that the total import between March and the end of July will be 150 cargoes. The cold weather has prevented the fruit from ripening rapidly and it cannot consequently be disposed of as fast as it comes. This of course tends to depress prices, which range $1 to $1·50 per bunch of 60 bananas. They are sold direct from the vessel to be sent all over the country. The damaged and over-ripe fruit is set-aside for the Italian venders in this city. Every sailing vessel arriving now from Baracoa brings from 2,000 to 4,000 bunches of red bananas, and from 20,000 to 100,000 coconuts. The supply this year will be over one-third larger than it was last year. The yellow bananas coming from Jamaica, Aspinwall, and Honduras, by steamships, in large quantities, are more in demand than the red kind. However a Baracoa planter who is in town says the flavour of the red is better than that of the yellow. He said the yellow were more in demand because dealers could make more money from them. They sell for from $1 to $2 per bunch according to size, and the bunches contain about 150 bananas while there are only about 60 in a bunch of red ones. Coconuts are selling for $34 and $35 per thousand and find a ready market at present. Pineapples are just beginning to come and are ont likely to be plentiful. The mangoes now on sale from Baracoa are not worth importing as two-thirds are rotten and have to be thrown away. Judging by late reports here an abundant crop of the delicious Jamaica oranges are expected. Every barrel of them shipped here finds a ready sale.—*Gall's News Letter.*

A FRENCH chemist reports that water made slightly salt, and to which, when boiling, bran in the proportion of one quart to every gallon has been added, has been found in a series of experiments to increase the yield of milk 25 per cent, if given to the cows as their ordinary drink.—*Indian Agriculturist.*

LONDON WHOLESALE PRICE FOR INDIAN TEA.—The following will give an idea of the rates charged by wholesale dealers to the trade in England for "Indian teas." :—

SPECIAL SELECTIONS, May 27th, 1882.

Half-chests Assam Orange Pekoe (superb quality; full full of golden tip; Matchless liquor).	3-1½
Chests Assam Pekoe (handsome leaf, little red, full of tip; extra fragrant; superb quality; great pungency; most attractive tea).	1-8½
Chests Assam Pekoe (handsome, tippy leaf; extra strong, powerful liquor).	1-5
Chests Assam Pekoe Souchong (semi-broken, regular leaf, free from dust and small; most intense strength).	1-4½
Chests Assam Broken Pekoe (handsome appearance; tipy; extra strong, with choice quality).	1-1½
Chests Assam Broken Pekoe (tippy; rather small; strong: with fine quality).	0-7½

—*Tea Gazette,*

TIMBER.—The strength of many woods is nearly doubled by the process of seasoning, says the *North-Western Lumberman,* hence timber used in its green state is not only weak, but is exposed to continual change of bulk, form and stability. Wood will always warp after a fresh surface has been composed, and will change its form by the presence of moisture. The effect of moisture on dry wood is to cause the tubular fibres to swell ; hence if a board be wet upon one side the fibres there will be distended and the board will bend. The natural law that governs the shrinking or contracting of timber is most important to practical men, but it is too often overlooked. The amount of the shrinkage of timber in length when seasoning is so inconsiderable that it may in practice be disregarded, but the shrinkage in transverse directions is much greater, and presents some peculiarities which can only be explained by regarding the structure of the wood as resulting from its mode of growth.—*Indian Agriculturist.*

REGARDING THE JAPANESE TEAS of the present season, the following remarks from the *Japan Herald* will be interesting to some of our readers :—We hear that, to-day 16th, two or three musters of the Second Crop Teas have been shown, and that the quality is considered very satisfactory, the leaf being carefully and well manipulated, and favoured by the fine weather which we have so far enjoyed this year; the cup quality is also excellent. The general character of Japan teas has been this season far above that of the last three or four years, and it may tend to restore them to the great popularity which they once held in the American market.—On the following day this appeared : We inserted, in our issue of last evening, a paragraph about the Japanese Tea Trade, in which—trusting to the universal dictum of all the *chazes* out here—we stated that the general quality of this year's crop was superior to ' that of the last three or four years.' However universal the opinion of the excellence of this season's crop may be out here,—if telegrams may be believed,—a contrary opinion prevails in the States. We are indebted to a friend for a copy of the following message, which was received this morning from New York, which is apt to cast a doubt on the minds of our own tea-tasters as to the accuracy of their judgment :—"New crop—quality not appreciated by buyers"—(this sounds like sarcasm on the reports sent from Japan)—"teas ex *first steamer* selling at *thirty-eight cents* per lb. Your export being excessive, importers are afraid of its effect on this market. Prospects are not encouraging." We commend this telegram to the consideration of the native merchants who are going in for the direct export trade.—*N. C. Herald.*

WHAT TEA TO MAKE.—The brokers say, that pale liquoring under-fermented teas, with greenish infusion, are not now in request. What is wanted is a good thick malty liquor, with a bright copper-coloured infused leaf.—*Tea Gazette,* July 15th.

RUBBER.—The *Indigo Planters' Gazette* asks:—"Have any of our district friends ever tried to experimentalize with the Ceara rubber tree? It is said to yield a quick and decent profit. It seemingly is likely to thrive in Tirhoot, for we saw a plant in a factory compound the other day over twelve feet high, planted about eighteen months ago, in very poor soil. Seeds are, we believe, to be had from the Secretary of the Agricultural and Horticultural Society."

THE AREA PLANTED WITH COCONUTS in the Fiji Islands is no less than 9,166 acres. Copra, which is the dried kernel of the coconut, is the largest in the list of exports, and its declared value at the Custom House was in the years—

1875	...	£40,003
1876	...	45,908
1877	...	79,403
1878	...	122,194

Thus in three years the trade in this one article has trebled itself, and as the settlers have been for some time extending their plantations, each year promises to yield an increased quantity. The coconut tree takes from five to seven years to mature, and returns are, therefore, slow, but nevertheless sure, and usually some other product, such as cotton, is cultivated in conjunction. About 50 coconut trees are planted to the acre, and in full bearing will yield an annual crop of about 100 nuts each. The acre will thus produce say a ton of copra, worth on the plantation £12 10s, besides coconut fibre, hundreds of tons of which are exported to Sydney, and used in various manufactures. The coconut industry is by no means an unprofitable one.—*Indian Agriculturist.* [In Ceylon the trees are not in full bearing under from 12 to 20 years, and the *average* yield of trees is not much over one-third of a hundred nuts.—ED.]

SINHALESE LABORERS FOR QUEENSLAND.—Evidently those who framed the notice for Sinhalese emigrants to Queensland, appearing in last night's *Observer,* are under a wrong impression as regards the laboring classes in Ceylon. It is a well known fact that laborers in Ceylon are chiefly composed of coast or Malabar coolies and country-born Tamils, and that there are but a few laborers among the Sinhalese who hire out their labor, and, of these, the number employed on coffee estates or acquainted with estate work is very small. The laborers on coffee estates are, as you know, coast or Malabar coolies under the conductorship of Jaffna Tamils. The Tamils from Jaffna are capital workmen. They also now form a large portion of the laborers on the estates: but they are as a rule employed in *building* and *planting.* It seems therefore that the term "Sinhalese" in the notice is used in a general sense, meaning not laborers who are Sinhalese *by birth* but *labourers born in Ceylon.* If the latter is the meaning, native Tamil laborers, who are more enterprizing than Sinhalese, will accept the terms advertised and emigrate : but, should it be confined to Sinhalese, it need hardly be said that the Sinhalese man, who is remarkable for his stay-at-home tendency, will not care to quit a life of ease and indolence for that of toil and separation.—*Cor.* [In a few districts, notably Rakwana and Western Dolosbage, Sinhalese laborers have often done good work for the coffee-planters, and even in Dimbula we heard last season of a proprietor who could get as many Sinhalese to come and work for him at a certain rate of advance per head, as he chose to have. Hard times are making the Sinhalese laboring people a little more reasonable in respect of plantation work.—ED.]

SILK.—It is reported that in view to promoting the silk industry in this country the Revenue and Agricultural Department have made arrangements for supplying such of the local Governments and Administrations as are prepared to join in the experiment with small quantities of silk-worm eggs of the univoltine variety, for the purposes of silk-worm rearing during the next cold weather. It has also been suggested to the provincial Governments that if the experiment is to be carried out on a large scale, the extended cultivation of the mulberry should be at once commenced in the localities selected for the trial and for this purpose cuttings of the *Morus multicaulis*, the kind of mulberry found much the best for the ordinary silk-worm, has been promised for planting during the ensuing cold season.—*Bombay Gazette.*

INDIAN TEA IN AMERICA AND AUSTRALIA.—The *Indian Tea Gazette* alludes to a circular letter issued by the Syndicate, dated Calcutta, June 20th, 1882. In this most satisfactory document it is stated that inquiries which come from Canada, Baltimore, and the Far West—places hundreds of miles apart [mark that], show that there is more interest taken in Indian teas every week; and the New York agents write that they are quite confident that a general curiosity to have samples of Indian teas would soon lead to deliveries of considerable importance *if they had the teas to offer*. In America, we are told that owing to the quantity of Indian tea on hand, the brokers were compelled to spread their sales over April and May, but they say if they had a sufficient supply to keep the tea before buyers, they could have done much better; for they add that unless they conserved their stock, *they would have none* to offer in June. It would never do to create a demand, and then be unable to supply it, and the American brokers have therefore done wisely to limit sales. But look at the resultant drawback. Here you have a market willing and anxious to deal with you, but stocks are insufficient to enable the trade to buy from you to the extent they would wish. Then as to Australia, the Melbourne agents write, "Supplies are nothing equal to demand, *and are far short of requirements.*" Need anything more be said to induce tea owners to support the Syndicate to the fullest extent. And if anything more were wanted, it will be found in the present and probable future low prices of Indian tea in England. We do not wish to unnecessarily sound a note of alarm, but as the organ and adviser of the Indian Tea Industry, we should be failing in our duty if we did not plainly point out that the present season does not promise to be a successful one as far as London prices are concerned. The heavy stocks at home must and will act prejudicially, and there is therefore every necessity to ship as much of our tea as we can, to new markets. It may be that high prices will not rule in these new markets, at present; but we have to face an almost certainty of low prices prevailing this season at home. The less tea, therefore, we send to Mincing Lane, and the more we divert to other places, the better necessarily will be our position. The Melbourne agents write:—"There is not the slightest reason, that we can see, why India should not command half the tea trade of Australasia, which is at present equal to 23,000,000 lb. per annum; but somebody must initiate the trade, to whom immediate profits are not of so much consequence as laying the groundwork of a large, steady, and profitable business in the future." Here is a prospect, and a brilliant one, before us. Let us not fail to take, in time, due advantage of it; and the way to do it is to strengthen the hands of the Syndicate by adequate supplies of tea. Mr. A. B. Inglis, of Messrs. Begg Dunlop and Co., writing from Melbourne, says: "Don't let shipments fall of, as it is most important to keep up a full supply, even in a little sacrifice in price, to get more people into the trade, until we are quite sure it is established. The consumers are everywhere taking to Indian tea, and I think all you have to do is to send plenty of it and watch the quality;" and a telegram, just received, says "Send more tea."

THEY DO THESE THINGS BETTER IN FRANCE.—So far as oyster-growing is concerned, this seems to be case. "Oyster Gardens" have been formed at Auray, in the Department of Morbihan, which in 1876 yielded 7,000,000, and in 1880, 33,000,000 oysters. The Abbé Bonnetard, parish priest of La Teste, near Arcachon, has invested an artificial system of cultivation, and the results are so remarkable that out of 151,000,000 oysters consumed in France last year, 97,000,000 were produced under his system.—*Public Opinion.*

WEATHER AND CINCHONA: LOWER AMBAGAMUWA; 28th July.—It has been raining for two weeks now almost incessantly. The storm is accompanied with thunder since today, and the rainfall is heavier. Portions of the estate exposed to the mousoon wind rapidly harden what little flush they put forth. Pruning is the order of the day and planting of course. In a field of about 20,000 succirubras three years old there is hardly a failure of 5 per cent. in the coffee under various aspects and situations. But in a clearing of 5 acres virgin soil, and with no other product, growing trees of the same age have succumbed cent per cent. Year after year they died out during the monsoon from damp. They are not wind-blown. This establishes what you say that cinchonas should thrive among tea, what with the long taproots to take up the moisture.

PLANT-FOOD.—A discovery, which may have some influence on the preparation of artificial manures, has just been made. A plant does not draw its mineral food from a fully-prepared nutritive solution, but prepares it itself by the direct action of its own cells with the particles of the soil where the food is stored up. M. Petermann has read a paper before the Belgian Academy in connexion with this subject, showing that the proper way of discovering what nutritive substances soils contain is dialysis rather than analysis. He shows that arable soils yield to distilled water, from which it is separated by a thin vegetable membrane, lime, magnesia, ferric oxide, potash, soda, chlorine, sulphuric acid, silicic acid, phosphoric acid, and even nitric acid. Arable soils, therefore, contain organic matters which easily pass through such a membrane as a cell-wall.—*Australasian.*

COORG, August 1st.—We are having over here one of the heaviest monsoons there has ever been: rivers flooded, bridges carried away, and tanks bursting on all sides. The monsoon came in very lamblike indeed. As for the first few days we had only a slight drizzle and splendid weather for planting, then it gradually increased in fury, blowing regular gales of wind for over a week, during which time we had more than 21 inches of rain: that is nothing however to the amount an estate in the Wynaad registered during the same week, *i. e.*, 51 inches.* However there is one blessing: we shall all I think get good clearings and good crops this year. Cinchona is getting on very well, especially in the Ghauts, but I think that is about the only other new product we have tried as yet. I am afraid we are not such a persevering lot as you over in Ceylon. One or two have tried cocoa, but with little or no success, though I see no reason why it should not get on as well in Coorg as in Ceylon. I expect a heavy dose of leaf-disease would bring us all to our senses and make us begin to think there are other things worth growing besides coffee.—L. J. P.

* An average of nearly 7½ inches per diem.—ED.

It is said that during last season more than seven billion feet of timber were cut in Michigan, Wisconsin, and Minnesota. The whole quantity of pine timber now standing in these three States, according to the latest reports, is 81,500,000,000 feet. The supply at the present rate of destruction will only last twelve years.—*Indian Agriculturist.*

PLANTING IN BURMAH.—The current number of the *British Burmah Gazette* contains an interesting report on the experimental cultivation of coffee, cocoa, cardamoms, black pepper, vanilla, nutmegs and tobacco carried on in the Mergui District by Captain Butler, the Deputy Commissioner With the exception of cocoa, there seems every prospect of the different plants succeeding.—*Madras Mail.*

ECONOMIC ENTOMOLOGY.—The city of Paris has granted to the Agricultural and Entomological Society land to the extent of 4,000 metres, in Montsourispark, on which it is intended to erect a school of entomology. In this school will be carried on the practical study of all kinds of useful insects, such as silkworms, bees, &c. Researches will also be conducted and experiments made, with a view to neutralizing the effects of noxious insects. Courses of public lectures will be given on all these subjects. Seeing how much France gains from useful insects, and how greatly she is suffering from such noxious species as the *phylloxera*, this movement is much to be commended.—*Australasian.*

HOW TO OVERCOME THE POTATO DISEASE.—By J. L. Jensen.—The director of the department of Agriculture at Copenhagen informs us that the average disease everywhere depends on the rainfall during the two weeks before, and the three or four weeks after, the time of ripening of the winter wheat. The reason is that the disease in the tubers is largely due to the spores falling from the diseased foliage, which are washed down by the rain to the tubers, on whose surface they germinate. His experiments "convincingly proved that perfect protective moulding (*i. e.*, covering with earth to a thickness of four inches above the upper surface of the uppermost tubers) can not only check the disease, but, if properly performed, is capable of reducing it to a minimum." Mr. Jensen also gives the results of his experiments as to the liability to disease of the different soils, and he suggests an improved form of plough to carry out his proposed method of cultivation. The pamphlet is well worthy the attention of practical agriculturists, and they will be glad to learn that the author is still engaged in further experiments.—*Bookseller.*

DESTRUCTION OF FIELD MICE.—The attention of the Revenue and Agricultural Department has been attracted to the plan adopted by French Agriculturists for the destruction of field mice, the damage done by which has, in the Department of Aisne alone, cost the farmers a loss of no less than 13 millions of francs. The measure hit upon is to construct heaps or small stacks of straw, to which the mice resort in myriads. These heaps are placed partly below the level of the ground and are securely packed and covered in, being first stored with poisoned beet-root, turnips and carrots. Much damage is occasionally done to crops in certain parts of the North Western Provinces and Assam which are infested by these plagues, and we understand that the Local Government and the Chief Commissioner have been requested to allow their Agricultural Departments to ascertain the result of similar measures in the tracts so affected. The circumstance that a sum of R50,000 was recently granted by the Government of India for distribution in villages on the frontier of the Hill tracts of Chittagong, of which the crops had been destroyed by field rats proves the importance of ascertaining the best remedy which can be applied in such cases.—Calcutta *Englishman.*

CINCHONA.—A very important discovery has lately been made in England which is likely entirely to revolutionize the cinchona industry in this country. Amongst the cinchona barks imported into Europe, one of an inferior quality, which only yields 2 per cent. of the alkaloid, instead of some 10 per cent. yielded by the higher quality of bark, has for some time been coming in increasing quantities from America. Attention was thus drawn to this particular bark, and, on investigation, it was found not to be cinchona at all, but an allied plant of the order of the *Rubiaceæ*. It used to be supposed that cinchona alone, the cultivation of which is difficult and expensive, was capable of yielding quinine, and therefore this discovery is one likely to have important results. Quinine may now be looked for among the members of the *Rubiaceæ*, and it is quite possible that some indigenous wild plant may be found in this country from which quinine may be extracted. Whether this be so or not, the American plant which has now been ascertained to yield it, might be easily enough cultivated over large areas in Bengal —in Tirhoot, for example, and in other parts where land and labour are incomparably cheaper than at our hill stations. Under these circumstances a yield of 2 per cent. would be more profitable than a yield of 10 or 12 per cent. from cinchona; and we may reasonably expect to be able soon to purchase quinine at half its present price. This will be an incalculable boon to the fever-smitten populations of parts of India; but the prospect is not so cheering to those who have invested their capital in cinchona cultivation.—*Friend of India.* [We doubt very much the possibility of the profitable cultivation of the trees which produce cuprea bark in the climate of Tirhoot.—ED.]

STRAWBERRIES IN THE NILGIRIS.—The present strawberry crop of France is reported to be the best for many years. Forty tons of fruit were a few weeks ago shipped in a single vessel for Southampton, and other shipments to England were made during the same month. This popular fruit grows well on the Nilgiris, and yet very indifferent attention is paid to its culture. A few years ago, strawberries were always to be had at Mr. Misquith's fruit-stall, but now we seldom if ever find a few dishes offered. During the warmer months, the fruit in Ootacamund attains a good size, and is of fine flavor. We have seen strawberries grown here from Australian varieties very large indeed, and, although these large kinds are invariably insipid, still with a little attention to the composition of the soil, this defect can be remedied. At Coonoor and Kotagherry, the climate is simply perfection for strawberries, but scarcely any attention is paid to the cultivation. Regular sale at remunerative prices can always be secured for strawberries. The method of cultivation is simple. They are grown in lines three feet from each other and half that distance from plant to plant. The best soil is of a light, rich, loamy character, which should be well trenched, deeply dug, and freely manured to sustain the plants for at least two years, after which they should be lifted and divided, or the fruit is likely to deteriorate. It usually happens that the fruit the second year is more abundant than in the first, though it is not so well flavored. When the blossom sets, it is sometimes necessary to thin out, in which case the crop, though not abundant, is well formed and luscious. At the time of ripening the fruit should be protected from birds with wire netting, and from insects that come out of the soil by freely watering the same with a weak solution of salt and water. If in addition to this a little fresh straw is placed under the trusses of fruit, it will keep them free from mud and grit, which is washed on to the fruit by rain or the watering of the plants.—*South of India Observer.*

CONSUMPTION OF TEA, &c., IN VICTORIA.

A large proportion of the tea used in other colonies of the Australasian group finds its way first to Melbourne, whence it is distributed. A copy of the *Australian Trade Review* enables us to give the figures for the actual consumption of the gold colony. The quantity increased from 5,786,067 lb. in 1880 to 6,495,776 lb. in 1881. This was an increase of 709,709 lb. in one year, so that we may safely take the round seven millions of pounds for 1882. As the population of the colony is, in round numbers, 900,000, this would be at the rate of about 7¾ lb. per head. As tea drinkers, therefore, the colonists of Victoria are very far ahead even of the inhabitants of the mother country. The proportion of coffee per head, however, is about the same in each country, not quite 1 lb. In Victoria the consumption was 787,886 lb. in 1880 and 863,768 lb. in 1881, an increase of 75,882 lb. Chicory is not separately shewn in the tables before us, but it is at least as largely used in Victoria as in Britain. Of chocolate and cocoa the consumption was 285,312 lb. in 1880 and 274,477 lb. in 1881, a decrease of 10,835 lb. Of sugar the consumption (that used in breweries included) is very great. The figures for 1880 were 573,951 cwt., for 1881, 608,784 cwt., an increase of 34,833 cwt. The consumption per head exceeds 75 lb. and is rising rapidly to the round 100 lb. It may be noted as a curious coincidence that the duty on tea in this colony, 3d per lb., is equivalent to £1 per maund. In Queensland and Tasmania the duty is the English figure of 6d, while in New Zealand 4d per lb. has been adopted.

TISSAMAHARAMA: PADDY AND NEW PRODUCTS: EUROPEAN AND NATIVE CULTIVATORS.

(*From a Correspondent in the local "Examiner."*)

Tangala, 30th July.—Let us gauge the cost of bringing 100 acres of land under crop under the primitive system of the goya, and the advanced and scientific method of the English paddyist. Having some knowledge of the former, I will take that in hand now:—The owner of 100 acres in one lot must needs have 20 men to watch his crop night and day for from 3 to 5 months running. These are not paid a daily or even a monthly wage; they get invariably a third of the outturn, the cattle-supplier, that is the owner of buffaloes used in ploughing, mudding and preparing the soil for the reception of the germinated paddy, gets another third share; and the proprietor of the soil, the remaining third; but this division takes place after the following charges are cleared off:—

1st One-seventh for cutting, stacking and threshing the crop.

2nd One-tenth Government share calculated on the original quantity.

3rd Fifty per cent interest on seed paddy.

4th Muandiram, or village headman's perquisite, at 10 curunies from every amunam (=6 bushels) extent sown.

5th One curuni from every amunam sown called Kenwi for the use of the village charmer.

6th One curuni from every amunam sown called Nekcetivi for the use of the village astrologer.

7th One curuni from every amunam sown called Pinwi for charitable purposes.

A 100 acre average soil field will give, all things fair, nearly 2,400 bushels.

After all these, and with the water rate of 50c the acre in districts where Government irrigation works exist, you will see how heavily handicapped the staple native industry is.

The soil all over Tissa is a stiff clay, and suited for purposes of cultivation only with unfailing irrigation available. If the tobacco plant takes kindly to the soil, all accessories for its successful and remunerative cultivation are at hand. In 1850 a tobacco plantation was started by the agents of Baron Delmar in the neighbourhood of Tangalla, and the quantity and quality produced were considered excellent by connoisseurs. The plantation was kept up for many years, but after the death of Mr. Straube, the Colombo agent, the experiment which had passed the tentative stage was unhappily abandoned. I have great faith in Liberian coffee and rubber proving successful in the more favoured portions of the district—those portions bordering on the Matara district. In the Kirame, Katuwana and Getamanne division, labour is plentiful and cheap, the soil is excellent, and the rainfall of sufficient average, and the cultivation of what are called new products need be no experiment, but will be an assured success, whilst the drier portions will afford a splendid field for the cultivation of the valuable varieties of the tobacco plant.

Hambantotta, July 29th.—The cultivation at Tissamaharama has, I am extremely happy to say, proved a decided success. To the best of my knowledge, an area of nearly 5,000 acres of land has already been sold to both Europeans and natives. Out of the 5,000 acres of land, nearly two-thirds has already been cleared of jungle, and the cultivation of paddy is going on vigorously. The cultivation at Tissa is now regularly being carried on both in Maha and Yala seasons, and sometimes three times a year, and in all appreciable returns have been obtained. Not only paddy, but other products, too, such as Liberian coffee, cocoa, citronella, plantains, and coconuts are reported to thrive well. A paddy landowner assured me that a few Liberian coffee plants are thriving well in his garden. On the whole, the place is making rapid strides towards regaining its former glory, and already good and substantial houses are springing up. Messrs. Wodehouse, J. W. Newington, F. F. Blatherwick of Aningkanda estate, and a European lady are the purchasers of the lands at Tissa. Mr. Blatherwick has caused to be planted some coconut plants on his land, the rest being planted with paddy. Machines for winnowing, grinding and husking paddy have been taken to Tissa by Mr. Newington, who is residing at Tissa, having built a good house there.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, July 15th.

Very great attention is given at present in France to irrigation. "Soil is female, water male," says an Arabian proverb. To be able to irrigate land appropriately is to bring fecundity, where, without such, the soil would remain sterile, despite all labor and manuring. But the agriculturists must be instructed how to employ, and economically, the water within their reach, from springs, rains and streams. The department of the Var is one of the dryest in southern France, and one which has most suffered in its vineyards from the phylloxera. Proprietors have employed steam engines to pump water from rivers and inundate the vineyards in autumn, thereby drowning the phylloxera to a large extent. The cost of plant &c.

amounted to 2,400f. per acre in the year 1875, when the flooding began to tell. In 1881, vineyards which six years previously represented but a dead loss, yielded a clear profit in wine of 1,000 francs per acre, or 25 per cent. The expenses would be very much less, where the water is furnished by canal, or tapped from springs. Small proprietors frequently unite to secure a water-supply, for, if submersion in autumn be not a cure for the phylloxera, it certainly minimizes its ravages. The value of water in vegetation is most advantageously ensured, when the irrigations are intermittent, instead of non-continued, between April and September: the sheet of water arriving on the soil after an interruption forces the stratum of air, which has replaced the first watering, to descend into the soil, renewing there the atmospheric oxygen around the roots of the plants. Two or three irrigations per week suffice. The same number of irrigations is not required for every kind of culture, as science has demonstrated that there is a connection between the weight of water which ought to pass by evaporation of the leaves through a yield, and the brut weight of that yield. That connection represents 60 times the yield in the green state: in other words, less the produce is green, less the quantity of water required.

A discussion is taking place respecting potato stalks as forage, either in the green state or in the latter when dried. The first point to consider is: how far the removal of the stalk affects the development of the tubers. Opinion is next to unanimous that, removed too soon, either before coming into flower or shortly after that stage, the formation of starch and dry matters in the tubers is arrested. The researches of Professors Nobbe and de Tharaud on this point are conclusive. Further, it is only after the formation of the flowers or aërial organs that the plant commences the rapid development of the tubers. Suppression or thinning of the stems is only justifiable when they are over luxuriant, and keep out air, sun and light from the soil. According to Stockhardt, the chemical value of clover as compared with potato haulm is as 3 to 2: he, and also de Stecher, testify that the haulm neither affects the yield of milk nor the quality of the butter: these drawbacks are only produced, when the apples or berries are attached. With 30 lb. of haulm, 15 of beet leaves, and 7 of straw, cows thrive well, suffering at first slightly from diarrhœa; the latter disappeared, so that 60 lb. of haulm could replace a proportionate reduction in beet leaves.

Oxen are extensively employed in farming operations; in summer their daily labour is divided into two periods, so as to avoid the hours of highest temperature. Taking 7 or 8 hours a day, as ample for them working, the oxen are yoked at two periods: from 4 to 8 a.m., and 4 to 7 or 8 p.m. White coloured oxen support the heat best, as do also those bred in the plains.

M. Pasteur is prosecuting new experiments bearing upon inoculation against peripneumonia in black cattle. So for his labours lead to the belief he will be as happy in his new field as he has been in the case of the *charbon* malady. Having stated he required funds to purchase subjects, the sum of 10,000 fr. was immediately subscribed by agriculturists and societies.

At the Chateauroux cattle show, a very simple and ingenious force pump with plunging piston was exhibited; the piston, which acts as handle, working in a small tube, sends the liquid into a larger one; the latter is in sections, the joints secured by indiarubber rings; it pumps 100 quarts a minute of urine, or well water; is eleven feet long, weighs 80 lb., throws a jet of liquid to the height of 23 feet, and costs 50 f.

Despite the prevailing rains, farmers count upon this being a happy season for cereals. The harvest in the south of France is over, but the drought has told on the yield. In these regions, canals, to irrigate the parched soils, are sadly needed. Green crops are making up lee way, but would be greatly improved by sun: the vineyards are not likely to realize their promise.

A gardener steeps the mats he employs to protect frames and conservatories, between October and May, for 24 hours in a solution of sulphate of copper, in a large hogshead; having allowed the matting to drain and become half dry, he plunges them for a few seconds in a solution of quicklime. Matting thus prepared will last, instead of one, seven seasons. The cord employed in the matting must not be oiled.

INFLUENCE OF CLIMATE ON PLANTS.

Mr. John Eliot Howard sends us the following cutting of a striking communication to *Knowledge* which we had previously noted for extract:—

In a number of *Knowledge* on which I cannot at present lay my hand, I noticed some facts with regard to the influence of climate on plants. It may interest your readers to know that plants feel severely the change in their usual habits which takes place when they are transplanted from Europe to South Africa. The Curator of the Botanical Gardens here, who has, perhaps, more practical knowledge of tree-planting than any man in the country, informs me that this is markedly the case with regard to fruit-trees. The reversal of the seasons, occasioned by the change of hemisphere, bewilders the plants, which are in some sense "educated" to such a degree that they are not able to survive the shock. The only chance of getting them to grow is by grafting, when they borrow the constitution of the tree on which they are grafted, and acclimatize readily. Ordinary deciduous trees behave very irregularly also. Sometimes they will pull through, sometimes they die, but the first cuttings never appear to thrive. I understand that evergreens are not affected. Birds take to the change of season well, if one may judge by the few European sparrows which have been introduced. European dogs generally die. Imported oxen and horses appear to do well, provided they receive the same amount of care which they experience at home. Cats thrive. Perhaps I may be pardoned if I suggest that the appearance of numerous articles from upholders of Darwinism in your capital magazine, must not lead your less scientific readers to imply that Darwinism is by any means universally accepted. It is, admittedly, only a hypothesis. I use the word hypothesis in the sense to which you restrict it in "Pleasant Ways in Science" (p. 315), as an opinion not based on phenomena. Dr. Mivart, one of the greatest of living anatomists, terms it, with all due solemnity, "a puerile hypothesis." May I be allowed to recommend to those of your readers, who are not terrified by mere weight of names on the other side to read carefully Mivart on the "Genesis of Species," Dr. Elam's "Winds of Doctrine," and Dr. Beale's "Protoplasm," in which they will find refreshing antidotes to the works of Darwin, Huxley, and Haeckel, the positive, comparative, and superlative exponents respectively of the fashionable doctrines in transcendental doctrine. Especially let them study well the history of "Bathybius Haeckelii," two unfit evolutions from the original Darwinic idea, which have ceased to survive. As a last suggestion (I hope you will forgive the space) may I remark that your magazine is extensively read this side the equator, and that some good maps of the southern sky would be appreciated both here and in Australasia. J. NIXON. Grahamstown, Cape Colony, May 4th, 1882.

COFFEE ADULTERATION AND THE BRITISH GOVERNMENT.

We call attention to the letter Mr. H. Pasteur has addressed to us, and we endorse every word of animadversion he has passed on the conduct of the home Government. Here is the report from the London *Times* of what took place in Parliament on the occasion to which Mr. Pasteur refers :—

DUTY ON COFFEE.

In Committee of Ways and Means, Mr. Courtney moved the following resolution :—"There shall be granted and paid to Her Majesty, her heirs and successors, upon every half pound weight of any article or substance called by any name of coffee or chicory, or prepared or manufactured for the purpose of being in imitation of or in any respect to resemble or to serve as a substitute for coffee or chicory, which is sold or kept for sale in the United Kingdom, and also upon every half pound weight of any mixture of such article or substance as aforesaid with coffee or chicory, which is sold or kept for sale in the United Kingdom, the duty of excise of one penny."

Mr. Magniac complained of the proposal being made without due notice. The imposition of the duty would aid the makers of horrible compounds in selling them as substitutes for coffee, of which they contained very little. It was immoral to facilitate the sale of these precious messes for the sake of increasing the revenue.

Mr. Gladstone said the Treasury were concerned with the collection of the revenue and not with adulteration.

Mr. G. Russell pleaded that the compounds were harmless, and were believed to be healthful, and they promoted temperance. The proprietors were willing to drop the name of coffee.

Mr. Warton detected a vein of satire in the last speech, and complained of the immorality of the Prime Minister's speech.

Mr. Magniac said it would alter matters if the name of coffee were dropped.

After further discussion the resolution was agreed to and reported to the House.

It is impossible to understand how a man so generally fair and clearsighted as Mr. Gladstone cannot see the absolute injustice he has inflicted on the producers and English consumers of coffee by his policy in respect of chicory and other coffee mixtures since 1852 onwards. As Mr. Pasteur points out, tea is most carefully guarded, and as a natural result the taste for tea has spread throughout all classes in Britain, while the so-called drinkers of coffee among the working classes do not know what pure coffee means. A correspondent of the *Pall Mall Gazette*, writing after Mr. Gladstone's budget speech and referring to the mysterious compound sold by the grocers as coffee, and the Government restrictions as regards chicory being mixed with it, says :—

"This applying the name 'coffee' to a heterogeneous array of products confounded altogether the element of price ; and one of the most valuable effects of the new orders will be to restore to coffee its true market price. This will greatly relieve commerce generally ; but it will, above all, relieve the planter of a serious burden. In India, in Ceylon, and in the West Indies millions of pounds sterling are invested in the industry of coffee-growing, and profitable employment is afforded for hundreds of thousands of English citizens. To free such an industry from the trammels of most unfair competition is only to perform a neglected duty towards a large and enterprizing class of industrial workers."

This ultra-Liberal journal, it seems, has been making a strong stand against the extreme views of certain Free-traders; for we read further in the *Produce Markets' Review* :—

In an article in the *Pall Mall Gazette*, headed "The Language of Trade," the following remarks occur ; and it would be interesting to know what the writer thought of coffee when qualified with the adjective "French" and "improved" by the addition of 50 to 90 per cent. of Chicory :—"In these days of free-trade one must view with considerable concern a tendency that has come into active existence of late years to abuse the power of language for classifying commodities for the purposes of trade. Every day we are learning that the vitalizing competition, which has so improved the legitimate relations of production and consumption, is now driving men to 'improve' the quantity as well, by the addition and the substitution of totally foreign products under the one established name. Every now and again consumers are forced to protest, and to act in their own defence. They have quite recently been urging, with reason, the complaint why, when they ask for coffee, they should have given to them stones of dates and pips of figs—why, when they order butter, they are to have foisted upon them lard or dripping ? And within the last few days we have learned that Americans have devised a means of utilizing skim-milk by combining it with a sufficiency of lard to form that we are told is "an excellent imitation of American cheddar." This may not be saying much for American cheddar, but the English consumer is none the less threatened with a commodity that it is to be known to commerce as "imitation factory cheese." Cheese we know, and like, as being the "exclusive product of the milk of animals." Factory cheese we know, and suspect. But what of this "imitation factory cheese," made up, apparently, of the discarded refuse of all-milk cheese thickened with a variety of animal fats ?"

In elucidation of the reference to "French coffee" we find the following in the *Home and Colonial Mail*:—

It need now be no longer a matter for speculation as to how a firm designating itself the London and Newcastle Tea Company can afford to give away with every pound of tea sold a "handsome present," for a case tried before Sheriff Russell here on Tuesday reveals what a large amount of profit the Company has by the sale of at least one article, viz :—coffee. The Company are the retailers of what is known by the public as "Game's French Coffee," and the article is manufactured in Manchester by a Mr. Pearson. This gentleman was examined in the Sheriff Court here on Tuesday, and in cross-examination, after hesitation, revealed the fact that Mr. Game, the head partner of the London and Newcastle Tea Company, was supplied by him with the article already mentioned at the low price of 9½d per lb., for which Mr. Game's firm charged 1s 4d, thus realizing a profit of 6½d on each lb. sold. This is trading at a rate somewhere like 33 per cent. The profit would be even greater, and the value of the article is even less, when it is taken into consideration that the packing of the article in tins costs 2½d. Now that this is an excessive profit for any retailer will be admitted on all hands ; and if the case served a good purpose at all, it served this, that the public are now in a position of knowing what they purchase when they go into a shop and ask for "Game's French Coffee." It is certainly difficult to obtain a conviction under the 6th section of the Food and Drugs Act, when the purchaser has been supplied with an article not of the nature substance, or quality of the article demanded ; and the only way that it will be possible to put a stop to the over-adulteration of coffee, mustard, &c., with other

substances, though not of an injurious character to health, will be to have fixed standards beyond which the manufacturer cannot go. The over-adulteration of whisky with water is not injurious to health, but still the party adding too much water can be prosecuted and convicted; the over-adulteration of coffee with chicory may not be injurious to health, but like the publican, the merchant excessively adulterating it should be liable to conviction.

Date coffee shareholders and dealers in other abominations are naturally jubilant over the unexpected barking-back of the Government; but they may not be able to exult long. The fight in so good a cause must be strenuously maintained, and the day cannot be far off when coffee in England will be placed on exactly the same footing as tea.

LAYING POOR LAND TO PERMANENT PASTURE.

Some down land on the chalk ridge between Guildford and Dorking was ploughed up some years since. It had been worth 2s. 6d. an acre in down, and, as it proved to be worth less than nothing in arable, it was allowed to revert to its original condition as a sheep run, and is now again worth about half-a-crown an acre as before. I need hardly say that no seeds were sown, and no expense incurred in laying this land down; and although the "facts and figures" which your correspondent inquires for cannot, I fear, be accurately arrived at, he will perhaps find no difficulty in admitting that down land, worth 2s. 6d. an acre, cannot very readily be rendered more productive, and would hardly pay the cost of much artificial treatment. I do not dispute that the 4,700,000 acres of cultivated land in Scotland might be increased profitably by the culture of some portion of the 15,000,000 acres of mountains, moors, and wastes, and that part of the 8,000,000 acres of waste or wild land in England might also be profitably cultivated; but the inclosure of uncultivated land seems for the present to have reached its limit, and at any rate there are many millions of acres whose appropriate crops are those which extract their necessary nutriment slowly from poor soils without cultivation—such as heather and the coarser varieties of grass.

No one doubts the potency of dung, and Mr. Lawes, who supplies cotton cake *ad libitum* to his cattle on the new pastures, would be the last person to deny the propriety of manuring grass lands in general; but when I recall the conduct of the grasses in the trial plots at Rothamsted and elsewhere, I can understand his doubts on the propriety of spending money for tillage and seed in the case of poor land like that which he described.

The boundary between land which will pay for cultivation and that which must be allowed, under present circumstances, to revert to its natural herbage, depends on various conditions, and partly, no doubt, on the skill of the occupier. Such a boundary exists, however, and the area of uncultivated land seems not unlikely to be enlarged.—HENRY EVERSHED.—*Field.*

SUGAR: OFFICIAL RETURN OF THE CROPS OF MACKAY DISTRICT, QUEENSLAND, FOR 1881-1882.

SUGAR.—On March 31st, 1882, there were 9,801 acres of land under cane, this acreage being held or farmed by 109 growers. Of the acreage it is estimated that 8,895 acres will be brought to the mills during the ensuing crushing season, and the crop estimated to be produced therefore is put down at about 8,000 tons, which amount, it will be seen, provides for a return of less than one ton per acre. We have strong hopes that this low estimate will be exceeded, and that the forthcoming crop will reach nine, if not ten, thousand tons, but we quote the estimate as put down in the return, merely remarking that the growers as a rule prefer to make their estimates so as to keep themselves on the safe side. So much for the prospect for the coming crop, and we now turn to that part of the return which refers to the past season. From this we learn that 7,167 acres of cane were cut and the produce manipulated in the 19 mills which were last year in operation, the result therefrom being 10,712 tons of sugar, and 407,020 gallons of molasses. A reduction of these figures gives a very satisfactory result for the season's operations as far as the return of sugar to the acre. This may be stated at 30 cwt., which shows a decided advance over the average of the previous year, which was only 25cwt. 2qr. The number of gallons of molasses to the ton of sugar will be seen to be just 40, that of the previous crushing being 39. There is no doubt that the prospect for the coming season would have been much brighter, had we not, in common with the whole of the colonies, suffered from the drought during the end of the last and the beginning of this year, but at the same time we have cause for congratulation in possessing the knowledge that during the present year the increase in the acreage of cane will be very large; estimate it to be at least 50 per cent, and consequently we the returns for 1883 may confidently be looked forward to as likely to be very good indeed, provided there is anything like a fairly good season. That there will be ample means for taking off this increased crop there can be no question, for we remark that it is noted in the return that there are no less than 10 mills in course of erection, and we learn privately that not one of these new mills has a capacity of less than 500 tons in a season, most of them in fact being what are generally spoken of as thousand ton mills. Such being the case we have no need to fear any difficulty in the way of taking off of the crop of 1883.—*Mackay (Queensland) Standard.*

THE PLAGUE OF CATERPILLARS IN ENGLAND.

(TO THE EDITOR OF THE "SPECTATOR.")

SIR,—I doubt if the interesting old records quoted by your correspondent throw much real light on this matter. Till lately, there were no trained observers of natural phenomena, and there was so little knowledge of their causes, that few could have been competent to judge whether one cause was more probable than another. Take, for example, the statement that, "In 1499, in Germany, vegetation was destroyed by blight and caterpillars together." I should ask (if there were any one to answer), *What* blight and *what* caterpillars? Of caterpillars, there are hundreds of different kinds that prey on vegetation, many with widely different habits; and as to "blight," that may be described as a term used by practical gardeners to make their employers believe they know all about it, when anything has injured vegetation. It is analogous to the railway guard's answer to the passenger who asks why the train is stopped, and is told, "Because the signals are against us." If the tender shoots curl up, or the rosebuds, instead of opening, turn brown, or the leaves look mildewed and spotted, or there is a great abundance of aphides, or hairy black flies, the gardener has one confident explanation, "It is a blight," and he probably adds something in a mysterious tone about the east wind having brought it. As to Schenkius's statement that the winter having been so severe as to kill nearly all the brute creation, the sunshine next summer was so hot as to set the trees on fire,—I do not believe Schenkius. I think it will be by such skilled and careful observations as those of Miss Eleanor Ormerod that we shall arrive at adequate knowledge on the subject. In the meantime, may I venture to offer the following general considerations:—

1. Since the number of individuals, on the average, remains the same, an enormous majority (say, ninety-nine hundredths) die without continuing their species. 2. Every insect has four stages to pass through in a year, sometimes in half a year or less, viz., egg, caterpillar, pupa, and winged insect; it is in the caterpillar stage that all the eating is done. 3. The caterpillar and the winged state, being the stages of exposure, are those in which most of the thinning takes place; and the latter is the more important stage in this respect, because by the time a caterpillar has grown large enough to be made a satisfactory meal of, it has already done much mischief. 4. In the caterpillar stage, the thinning effected by birds, tree-hugs, carnivorous cater-

pillars, &c., is enormous. Ichneumon flies are not to be included, for though they kill, death does not take place till the caterpillar is full fed; and, in the meantime, the young, parasitic family they provide it with has probably increased the caterpillar's voracity. 5. In the winged stage, also, immense numbers are destroyed by birds and by bats and carnivorous insects. 6. But none of these checks on multiplication, nor all together, appear to be sufficiently variable to account for that sudden increase in caterpillars in some years that is spoken of as a plague; the question arises whether we do not find such a check in the weather. I doubt whether any one who has not been a practical entomologist has an adequate conception of the thinning effect exercised by unfavourable weather on insects in the winged state, or the correspondingly quickening effect of weather that is favourable. The effect is concentrated, because the existence of insects in this state is brief—a few days for an individual, a few weeks for a whole species—and it is strong, because in this stage they are so sensitive to it. It is not merely that rough weather destroys them, and that in windy weather they do not fly, but the mere absence of sunshine is enough to prevent many species from moving at all. Like the "pale primroses," but in a different sense, they,—

"Die unmarried, ere they can behold
Bright Phœbus in his strength."

The sunless summer of 1860 nearly exterminated from some of the Sussex and Hampshire woods several species which had formerly been plentiful there. A rainy fortnight may produce such an effect on a species; on the other hand, a hot fortnight at the right time may foster an immense increase in the number of fertile eggs laid. Even when the species does not require sunshine, greater or less warmth makes a vast difference in the numbers on the wing; in hot weather, the lightest touch of the beating-stick brings them out in swarms, while in ordinary weather they are difficult to rouse.

I need scarcely add that the circumstance that a principal cause of insect plagues—the weather—is beyond our control, affords no argument against the use of such means of keeping them under as are within our power to influence. Chief among these means seems to be the preservation of those vivacious inhabitants of our woods and gardens, some shy, some impertinent, but all (except sparrows) delightful, our wild birds.—I am, sir, &c., F. MERRIFIELD.

Brighton, July 10th.

[What's the matter with the poor sparrows?—ED. *Spectator*.]

THE TAVOY PLANTING DISTRICT.

RANGOON, 19th June 1882.

As the Chief Commissioner has been advertising grants of waste land in the Tavoy District for planting purposes, I dare say some remarks on the description of this place will be of no little interest to several of your numerous readers.

The Tavoy District is on the Moulmein side, in the Tenasserim Division, extending along to the eastern side of the Bay of Bengal, from 13° 15' to 15° 11' N., bounded on the north by Amherst, from which it is separated by a range of hills south of the river Re; on the south by Mergui, and on the east by the high chain of mountains which form the boundary between British India and Siam.

Its extreme length and breadth is about 150 and 50 miles respectively, and has an area of 7,200 square miles. Its general aspect is that of a long sea-coast tract, hilly and densely wooded, enclosed by mountains on three sides, and open on the west towards the sea.

Some of these mountains reach an elevation of nearly 6,000 feet. There are two rivers, the Tenaserim and the Tavoy; the former being remarkable for having two sources, one of which, rising in the north, flows south to the village of Metta, where it is joined by the latter. After uniting, they flow due eastward, and then turn south, entering the Mergui District. The greatest part of this river is dangerous to navigate on account of its rapids. The Tavoy river, however, flows south through a narrow valley, being fed by numerous mountain torrents. These mountains appear to be of granite, with the exception of a few, which consist of clay and slate. Gold is, I hear, to be found at the head waters of some of the streams, though never worked. With the exception of the valleys, the whole surface of the Tavoy country is covered with dense forest, which has never been cleared, beyond patches here and there, in the vicinity of the villages. Travelling is extremely difficult on this account, and more so, as there are no roads to travel by. Many of the trees are found to produce a bright gamboge.

The cool season commences at the close of the rains' in October, and continues until the middle of February' when the hot weather prevails. The rains begin in May' and continue to the middle of October, although slight showers frequently occur in the cold season, when the weather is pleasant; the thermometer scarcely reaching 85° in the shade, and sometimes, in the mornings, falling as low as 56°. The winds prevail from the east, and are of a very considerable force, especially in the monsoons. During the months of December, January, and February, heavy fogs prevail in the mornings till about 9 o'clock, and it is at this season of the year that the greatest thermometric range is observed, occasionally as much as 30° in one day. The rainfall varies from 160 to 220 inches in the year. The average during the months are, January to May, 30 to 40; June to September, 160 to 180, and from October to December, 1 to 10. The temperature in the shade varies during the day, as in Rangoon. The area under cultivation is barely more than 1-17th of the whole area of the district, yet there are 3,550 square miles of waste land lying idle waiting to be cultivated. The best soil to be found is in the Amherst district, to the north.

The products at the present moment are chiefly rice, sugarcane, beetle-nut, dhanee, pan-vun, and mixed fruits and likewise a small amount of cotton, fibres, tobacco, and vegetables. In addition to this, there is a large hill-garden cultivation. The soil is not considered particularly rich, and the average outturn of rice is 1,270 lb. to anacre. In fruit trees the country is very rich, containing many varieties.

The average prices of labour I quote from the Administration Reports:—Daily hire of a skilled labourer, Re. 1-4; unskilled As. 8; and that of a cart, Re. 1-8, whilst that of a boat is Rs 7. The manufactures are salt and earthern pots, of which the former is made from sea-water, and entirely consumed in the district. Up to the present moment no European has attempted to plant in this district, except Mrs. Helfer, the wife of Dr. Helfer, a German. She started a plantation in 1840 at Mergui, and, having lost her husband shortly afterwards, who was killed by the natives in one of the islands in the Archipelago, she trusted the estate to her brother, He eventually, through sickness, had to leave, so that the plantation was without anyone to manage it. This lady, becoming involved in some difficulties of a pecuniary nature, neglected to go out again, and in the meantime the German Government were entering into negotiations with the East Indian Company regarding the land, so that the plantation became completely wrecked through want of attention. The plantation at the time consisted of 2,000 acres, and contained 150,000 young areca palms, 6,000 nutmegs 6,000 coffee plants, and 50,000 coconuts. Mrs. Helfer has written a book known as "The Travels of Dr. and Mrs. Helfer," and from her remarks, it would lead me to suppose that, until these complications I have mentioned above arose, the plantation was in a flourishing condition. Since then, as I have stated, no other European has attempted to cultivate this vast amount of waste land. Mergui, I should say, is not in the Tavoy District, being slightly to the south. I am informed on very reliable information that it would occupy planters a few years before they could clear the jungle. Labour is most difficult to obtain, either from Bengal or Madras, and, when the coolies do arrive, they are generally very independent. I have known an Engineer on the Sittang Railway, which is under construction to Tounghoo, take some hundreds of coolies up to river to work, but they all returned as they said they were unable to live. My firm opinion is that the Tavoy District is more favorable for mining operations, in which the country is very rich, rather than for planting purposes.—*Indigo Planters' Gazette*.

[From what is stated in this article, it is evident that the great difficulty planters in the hill-country of British Burma will have to contend with is that regarding labour, which is, at present, scarce and dear.—ED.]

TEA SOIL AND MANURES.

The following is a report by Mr. Joseph Cripps, the well-known analyst, upon some samples of Assam soil submitted to him by one of the leading Indian Tea Companies. He says:—

"These soils appear to have been formed by the disintegration of granitic rocks, and contain but little available plant food, the insoluble silicates alone ranging from 84 to 93 per cent of the air-dried samples.

"Lime is found in small quantities, existing either as silicate or sulphate, and in my opinion the free use of lime, either as quicklime, marl, or carbonate, should be one of the first steps taken in the future management of such soils. Quicklime should only be used, however, provided it can be followed up by a liberal dressing of organic manure, dung, decaying vegetable matter, or such like substance.

"Potash and phosphoric acid are also deficient. It will be noticed that the amount of oxide of iron and alumina is much greater in the soils taken at depths of 1½ to 3 feet below the surface than in the soils marked surface, and, as the iron exists as protoxide in the lower depths, lime will have a very beneficial effect, and, as opportunity is afforded, I would advise that more of the subsoil be incorporated with the surface soil by digging or deep ploughing.

"This will bring up stores of phosphoric acid and potash, which are now practically unavailable.

"The tea plant, as will be seen from appended analysis, is one which extracts from the soil very large quantities of potash and phosphoric acid, and it is to the replacing of these constituents that the attention of the grower should be directed. It would appear that phosphoric acid and potash are most necessary for the full development of the tea plant, and, unless stores are developed from the subsoil, or their constituents are applied in the shape of manure, the soil will become exhausted, and disease of the plant a natural consequence of such exhaustion. The disease known as 'red spider' is most likely one of the results of this exhaustion, and it must be evident that soils robbed of nearly all their available soluble constituents can only grow plants of a delicate and languishing character.

"For a full and vigorous growth of plant, to be followed by the production of a crop of leaves so rich in phosphoric acid, potash, and nitrogen as is tea, a regular feeding of the plant by good rich fertilizers must be absolutely necessary.

"I understand that plants which get a fair start and have plenty of fertilizing matter to draw upon are seldom attacked by red spiders or any other parasite; while, on the other hand, as soon as a plant, from want of necessary supplies of food begins to languish, it becomes a prey to disease and blight.

"The appended analysis of tea will show how large is the amount of phosphoric acid and potash required for the full development of this plant.

"Composition of the ash of tea:—

Potash*	39·22
Soda	·65
Magnesia	6·47
Lime	4·24
Oxide of Iron	4·38
Protoxide of Manganese	1·03
Phosphoric Acid	14·55
Chlorine	·81
Sulphuric Acid	trace
Silica	4·35
Carbonic Acid	24·30
	100·00

"Tea is also very rich in nitrogen:—

Pekoe, containing	6·58
Gunpowder „	6·62
Souchong „	6·15
Assam „	5·10

One of our home manure manufacturers, acting on the above, sets forth that his manure for the tea tree will be found to sustain and nourish the tree in the production of a luxuriant development of frequent flushes of leaf; and as it is not an unduly stimulating manure, neither the tree nor the soil are overtaxed, or their future fertility drawn upon.

"The basis of the manure is the mineral matter necessary for the vigorous growth of the tree combined with nitrogenous salts and *animal organic matter* for the production by decomposition in the soil of ammoniacal and carbonaceous constituents. The advantage of supplying these elements, in conjunction with the mineral ingredients required by plant life, cannot be over-estimated; for, by the decomposition of organic matter—and most valuable of all *animal* organic matter—carbonic acid and other solvents, are generated side by side with the mineral matters, rendering not only such of these as are artificially supplied in the manure, but those also which the soil itself may contain, available for the sustenance of the plant."

The following is a guaranteed analysis of this manure:—

20 to 22	per cent soluble Phosphate of Lime.
4 to 6	„ undissolved „
3½ to 4	„ pure Ammonia. „
4 to 5	„ pure Potash.* „

There is no doubt that as time goes on, and soils become exhausted, more and more attention will have to be given to the question of manure; but to attempt to re-fertilize a soil without ascertaining first in what respects it is deficient, is only to waste money. Therefore analysis of the soil of a garden should be carefully made before it is decided what manure to apply.

In some cases artificial manure to suit the required purpose could be made on the spot, for the carriage cost of an article of such bulk is a serious matter; but even if manure could not be so well or safely made on the garden, there is no reason why it could not be made in Calcutta. It has always struck us as particularly absurd that people should go to the expense of importing at great expense what can so easily and far more cheaply be made in this country.—*Indian Tea Gazette.*

* In coffee beans the proportion has ranged as high as from 40 to 52 per cent.—ED.

THE BOTANIC AND AFFORESTATION DEPARTMENT, HONGKONG.

REPORT FOR 1881.

The following Report from the Superintendent, Botanic and Afforestation Department, is published for general information:—

* * * *

AFFORESTATION.

17.—The following is a tabulated return of planting operations during the year:—

Pinus sinensis, one year old, ...	97,695
Pinus sinensis, 3 years old, 3 to 5 ft. high, ...	3,776
Pinus sinensis, *in situ*, ...	649,587
Pinus Thumbergii, *in situ*	7,000
Eucalypti	4,347
Stillingia sebifera, (Tallow Tree) *in situ* ...	6,000
Quercus salicina, and Q. Harlandi	2,115
Quercus Japanese spp.	2,240
Rhus succedanea, (Wax Tree) *in situ*	1,800
Melia Azederach (Pride of India)	1,110
Bamboos	654
Syncarpia laurifolia, ...	344
Castanea (Chesnut) *in situ*	300
Albizzia Lebbek	319
Cocos nucifera (Cocoa-nut)	196
Aleuritestriloba (Candleberry Tree)	180
Ficus retusa ("Banian")	71
Dammara robusta	61
Aleurites sp.	26
Miscellaneous	93
	777,914

18.—The total number—777,914—of trees planted shows an increase of 566,899 over the previous year's work, *i.e.*, the number has been nearly quadrupled. This year we expect to make an increase of about a quarter of a million over those planted last year, which will make a total for the

* While the analysis of the leaf shews in round numbers 40 per cent. So that the preparer of the manure must agree with Mr. Hughes that, besides the potash in the soil, there is a considerable proportion in the phosphate of lime.—ED.

season of 1882 of over a million additional trees for the colony.

19.—As will be seen from the above table, many kinds of trees beside the Chinese pine have been planted. Some of them are put out for experiment—and I have great hope that they will succeed—but others are of indigenous trees which are certain to do well. A few of them, as the Japanese wax tree, the tallow tree and the pride of India, will probably furnish valuable products, as they do in China and Japan, such as wax, vegetable tallow, and timber, besides the great addition of diversity of form and colour which they will make to the beauties of the future sylvan scenery.

20.—Roadside planting outside of the town has been extended on both the Pokfoolum and Shaukiwan roads. About a mile of the former, and a little less than a mile of the Shaukiwan road, was planted. The trees used were bamboos and "banians." Many of the former were purchased from Chinese on the mainland. The "banians" were translated from the Botanic Gardens, Bowrington Plantation, and other places where they were no longer required. The dimensions of these trees ranged from 7 feet 2 inches down to about 1 foot 6 inches in circumference, at three feet from the ground; in height, after about half the length of the branches had been lopped, from 25 feet downwards to 10 feet; and their ages were from about 25 years down to 10 years. A few of these trees were much damaged by the large larvæ of a species of *Longicornes*. Many kinds of trees here during the weakened condition of their health, consequent on removal, are very subject to attacks from species of *Longicornes*. The eggs of the *Longicornes* are deposited in the bark, and when they hatch the larvæ subsist by consuming the inner portions of the bark, thus causing much injury to, and sometimes the destruction of, the tree.

21.—By the typhoon of the 14th October 20 trees in the streets and roads were blown down, most of which, however, were replanted in their old positions or conveyed to, and planted in, more suitable sites.

22.—Ten nurseries in Hongkong and Kowlong have been maintained. The trees—small seedlings—in two of these, which are situated at considerable altitudes—900 to 1,100 feet—suffered severely in the October typhoon. Although, for the sake of saving labour in the transport of trees, it would be very desirable to maintain nurseries high up on the hills, in the middle or vicinity of intended planting grounds, the damage done by this typhoon to the seedlings points to the inadvisability of risking quantities of tender seedlings in nurseries in high and exposed positions.

23.—In the beginning of the year Forest Guards were appointed to protect trees and shrubs from the depredations to which they were constantly subject, and also to control the goat-keepers in regard to the lands used for grazing purposes. For the protection of the young trees it was found necessary to interdict certain lands for grazing purposes and grass cutting, and to allot lands where goats and cattle might be permitted, and where grass might be cut. The result of the appointments has been very satisfactory. Tree cutting has been very much checked, and the cutting of large pine trees, which had gone on very much, has been almost entirely stopped, except at Little Hongkong, where there have been two or three instances of a number of good sized trees being felled and carried away. The villagers report that the cutting was done by night by boat people who landed at Deep Water Bay. I have much reason for believing, however, that the villagers themselves are the culprits, and to put a stop to this tree cutting it may be necessary to adopt more stringent measures.

24.—Hill fires have occurred in several places. In the vicinity of the Chinese Cemetery on Mt. Davis the grass was set fire to twice—by worshippers at the Cemetery, I believe; in the first instance the fire destroyed about 5,000 healthy trees which had been planted only a few months, and in the second case about 500 trees were burnt.—I have the honour to be, Sir, Your most obedient servant: CHARLES FORD, Superintendent, Botanic and Afforestation Department.

The Honourable W. M. Deane, M.A., Acting Colonial Secretary, &c., &c., &c.—*China Mail.*

FRUIT-GROWING IN QUEENSLAND.

Among the objects of interest to be seen in the neighbourhood of Maryborough the most attractive to a visitor from the south are the Willow-vale gardens, the property of Mr. John Cheyne. These gardens, which are certainly the most famous in the district, are situated on the south bank of the Mary River, about four miles from Maryborough. The road out is a very uninteresting one, being through a sour-looking forest country in which there is a deal of undergrowth and very little grass. On approaching the bank of the river the character of the soil and the appearance of the country suddenly change for the better. The flat monotony of the forest is replaced by pleasant swelling banks, on which the grass grows luxuriantly. Nearer the river the country is covered with fields of maize and sugar-cane, and in one of the most pleasant spots in view are situated Mr. Cheyne's gardens. The area of the property is about 25 acres, of which a considerable portion is given up for flower-growing, the Willow-vale bouquets being considered far superior to any other. On entering the ground the fine dark green of the orange trees at once attracts attention. The trees here grow much healthier than in any place in Queensland that I have yet seen, and the fruit is extremely fine. All kinds of oranges are grown, there being 16 acres planted with this fruit alone. Some of the mandarins are very well grown, and of excellent flavour. The trees are planted 20ft. apart and the ground between kept thoroughly clean, a horse hoe being used occasionally when the condition of the soil is favourable. At present the ground is so hard that it is being gone over with the hoe. Like everywhere I have been in Queensland, this district is suffering from the effects of a severe drought. Last season was considered the worst, by a long way, ever known in the district, and yet the trees are all healthy, with a fine dark foliage, and plenty of fruit. Mr. Cheyne attributes his success with his fruit trees (of all kinds) during the drought to deep cultivation, the whole of the ground where the trees are planted having been thoroughly trenched. The oranges are sent to market at Brisbane and Sydney, and a good many cases find their way to Melbourne. Few lemons are grown, this fruit not appearing to be in such demand in Maay borough as it is in Melbourne. Limes, however, grow well and yield plenty of fruit. Of the fancy kinds of orange the cumquat does the best, the fruit being much fancied by those who are used to it for eating as well as for preserving. About two acres are planted with pineapples, the rough and smooth varieties being pretty equally represented. They are planted in double rows with a space of about 5ft. between. The ground is kept perfectly free from weeds, and the plants are better grown and more healthy than any I have seen in the country. In the proper season the smooth-skinned pines grow to a large size. The finest are sent to Sydney for sale, and I have been informed that they are scarcely ever kept there, the cases being redirected for Melbourne, whither they are at once forwarded. For the finest pines Mr. Cheyne considers he is fairly well paid at 1s each. Those who buy the fine large pines occasionally seen in Melbourne fruits hops can guess at the profit made by the dealer and retailer Owing to the bad season, the pines this year have not been so fine or so plentiful as is usually the case; but in walking through the ground I saw many very fine ones, the most numerous at present being the smooth-skinned variety. Next season Mr. Cheyne intends increasing the area under pines. The next fruit in importance is the banana, for the growing of which a space between the high bank and the river is reserved Some of the bananas grow here to a considerable height, while the foreground is occupied with the dwarf varieties. The soil in this part of the ground is very rich, the plants are well looked after, and they are all in excellent health. The crop in fair seasons is a heavy one, and sells wholesale at 4d per dozen. None but the finest varieties are grown. These three fruits—the orange, the pine, and the banana—represent the main crop; there are, however, many other fruits coming into bearing, which, in the course of a year or two, promise to equal any one of the three fruits named. Of these the glorious mango is the most important. This fruit grows to perfection at Willow-vale, and commands a ready sale at Maryborough. The trees are as yet young, but they are handsome and well grown, and evidently very

healthy. The crop will steadily increase every year, and it is extremely probable that in half-a-dozen years mangoes will be freely grown in the neighbourhood, whence they can be shipped in any quantity to Melbourne. The guavas all do well; the principal varieties grown by Mr. Cheyne are the cherry, the gooseberry, and the common guavas. All three varieties give heavy crops of excellent fruit, the most fancied being the gooseberry guava. Several varieties of the custard apple are grown, the trees yielding considerable quantities of fruit. The Chinese date-plum does so well that it is likely to become a common fruit in the district. Loquats are also well represented, and grapes do fairly well, but the wood is weaker and not nearly so healthy-looking as in Victoria. The American varieties appear to stand the climate better than the European grapes, the most hardy and the best bearer being the Isabella. Mulberry trees are grown in moderate quantities, and yield good crops. Besides the fruits named, Mr. Cheyne has planted a number of tropical fruits as an experiment, with the view of ascertaining that fruits will succeed in the district. Of these fruits the Lee-chu Brazilian cherry and Chinese dwarf peach have succeeded better than any other. The tamarind tree has grown to a good size, and is beginning to fruit. The cinnamon has thriven exceedingly well, and should pay well for cultivation. Apple trees grow fairly well, but owing to the climate the tree has no rest; blossoms and fruit come at all times, but the fruit is almost useless. Only one variety of pear will grow, and that is only fit for cooking. Peaches do not pay for growing, as the fruit is attacked by the flies before it is fit for picking, and is thus rendered unfit for use. The Chinese dwarf variety comes to maturity before the flies attack the fruit, and thus escapes. This peach is worked upon a common stock, and, when it has a year or two's growth, it has a peculiar and very attractive appearance. The orchard has a very serious enemy in the great troupes of flying foxes which often visit it, when they do an immense amount of damage, as they not only eat a large quantity of fruit, but destroy twice as much as they eat. Near the dwellinghouse are some very fine flowerbeds, which in the season must present a most beautiful appearance. Some very fine varieties of roses are grown, all of which give splendid blossoms. The camellias have a handsome appearance, with a great promise of blossom. Many varieties of European flowers grow well, and there is a fine collection of the flowering tropical bushes that present such an attractive feature in all well-kept gardens in this neighbourhood.

Notwithstanding the heat of the weather (for though it is winter time now the temperature is almost equal to that of a Victorian summer), this part of the colony suffers at times from frosts which, though, as judged by a Victorian standard are very mild, are yet sufficient to injure many of the tender tropical plants. When the weather is at all inclined for frost the most rare and tender plants are protected, the pineapples being covered with dry grass, which effectually prevents the frosts from injuring the fruit. If the frost once touches a pine, it is entirely ruined for sale, and but for the boys, who in all countries are ready to take damaged fruit at a considerable reduction, they would be thrown away.—*Australasian.*

TEA IN UPPER INDIA.

The saying that "a good tea climate is necessarily an unhealthy one for the planter," has almost acquired axiomatic force, and is taken for granted without the slightest attempt at cavil. We are, however, not prepared to accept it in its entirety. We are perfectly aware that every tea district in India has in turn been unhealthy, and that many are so still, and we are even prepared to admit that the best tea districts are likely to deserve a bad name in this connection. At the same time we deny that there is any unalterable connection between a good tea district and an unhealthy one. The great causes of unhealthiness are incidental to a rich vegetable growth, and as a rich vegetable growth is necessary to make a tea garden a complete success, we can easily understand how the idea has taken such a firm hold on our imagination. We know many gardens which in their early days were perfect hot-beds of fever, but which are now comparatively healthy—as healthy, in fact, as we can look for in a tropical climate. The Western Dooars district has a bad name in this way, and it is a name that will possibly be difficult to remove, because it will always be more or less deserved, but we anticipate a comparative immunity from fevers, when the country is opened up, and the jungle growth kept under, as will be the case when a large number of gardens are in working order. The gardens in Upper India form a class perfectly free from this drawback. The climate for the greater part of the year is about as near perfection as possible, and only during May, June, July, August, and September is there the slighted inconvenience from heat. Most people dispense with punkahs altogether. For five months in the year, fires are welcome, especially in the morning and evening, and during the winter months, white frost covers the grass till breakfast time. To one accustomed to see tea cultivation in the Assam districts, it seems quite impossible that it should grow so as to be a commercial success; but there is the stern logic of facts to put against this idea, and notwithstanding the cold and bleak feeling in the mornings and evenings, for so many months in the year, there is a splendid outturn obtained during the tea season proper—from April 1st to November 15th. The temperature ranges from 35° * to 90°, with a mean of 70°, and an annual rainfall of 85 inches. This seems to be dead against another traditional axiom, *viz.*, that tea will not pay, commercially, under a rainfall of 100 inches. It does not, however, run counter to it, as the saying referred to must be taken in connection with a tropical climate. Now the district we are speaking of—Dehra Doon—as typical of the tea gardens of Upper India, has not by any means a tropical climate. It follows, therefore, that the evaporation is much less than in a hotter climate, and a lighter rainfall suffices.† The rainy season lasts from the middle of June to the beginning of November, and is supplemented by a week's fall about Christmas, and three week's rain in March. This latter starts the spring flush, which is ready for plucking on or about 1st April. The season then continues to the middle of November with a break of about three weeks in the early part of June, just after the spring crop has been gathered, and before the big rains commence. The only climatic drawback is the hot wind,‡ this is a veritable plague, but it is fortunately not an annual visitation. Possibly one year in 4 or 5 is about as often as those winds blow with such power and duration as to retard growth. In the spring of 1876 they were very severe, and those gardens situated in the Western Doon, near the Jumna, suffered severely. Quite six weeks were lost, during which time the leaves crumpled up like singed brown paper, and tea manufacture was an impossibility. The wind enters the Doon from the plains through the wide gap in the Sewalic Range, formed by the passage of the River Jumna, and those gardens in the vicinity suffer severely. The gardens further east, and in the neighbourhood of the town of Dehra, do not suffer so much, because of the protection afforded by the forests intervening. Many gardens are now being protected by belts of timber on their western boundaries, and these will speedily grow up and make the hot winds cease to be a bugbear. One very large garden is entirely free from any evil effect of these winds, from the fact of trees being planted on both sides of every main road in the plantation. The jat of plant is the ordinary China (*Thea Sinensis.*) There are many sub-divisions of the *Thea* family, but for all practical purposes the following list is sufficiently complete —

Thea Sinensis	...	The China variety.
Thea Assamica	...	The Assam indigenous.
Thea Hybrida	...	The different hybrids.

In the early stage of tea-planting, the late Mr. Fortune

* In Dimbula, at 4,000 feet above sea level, only once during about ten years' observations was the thermometer known to go below 45°. But while our minimum is 10° higher than that of Upper India, our mean in consequence of our lower maximum heat is about 5° lower, that is, if the figures in this article are strictly accurate. We can say from personal experience that the cold on a February evening in the Dehra Doon at 2,000 feet in 30° North was bitter. But, in the hot season, the Europeans of Dehra go to Mussoorie, 5,000 feet high up.—ED.

† N. B.—ED.

‡ Utterly unknown in Ceylon.—ED.

was deputed to go to China to study tea-planting, and he forwarded seeds to the Indian officials for the purpose of experimenting in India. These, we believe, were planted out in Kumaon, one of the earliest—if not the very earliest—gardens was Hawalbagh, which was only recently disposed of to Dr. Oldham. From that nursery—for it was little else—seedlings were distributed to the neighbouring districts, and hence it comes that the variety in vogue in the Upper Provinces is the common China. Various experiments have been made with the Assam indigenous variety, and also with the hybrid, but the generally received opinion, until very recently, was that the climate did not suit these jats. We feel convinced, however, that the plants never got fair play, inasmuch as the mode of planting out the China seedlings, peculiar to the Doon, was followed in the case of the others. This plan is to compensate for the small habit of the China plant, by planting several seedlings to form a bush. The general rule has been to plant, from 3 to 7, or even more, to form a bush—we have ourselves counted 32 in some cases.* The consequence is, that an Assam indigenous or hybrid has no chance of living under such treatment. The China plant is in all essentials a bush, whereas the others develop the habit of a tree, and we would never think of planting seven fir trees in one hole. About the year 1876, a popular medico, with a penchant for tea, planted out a few acres of hybrid by way of experiment, and took the precaution to plant them singly. Here and there where the seedlings were delicate, he planted two, with the intention of eradicating which should turn out the weaker, and the result justified his good sense. They grew apace, and when the writer saw them last, in 1878, they gave promise of being the nucleus of a good garden. We feel sure that hybrid will there, as in other districts, turn out the favorite. In 1876, an unusually long spell without rain, told very heavily on the gardens, and on all sides the ravages caused by the heat were visible, while a few hybrid and indigenous scattered here and there over the gardens, showed no sympton of feeling the drought at all. The reason was of course not far to seek. The tap root of the tea plant goes deep into the earth, and this is particularly true of the hybrid, whose root we have traced to the depth of seven feet,† hence bushes with such tap-roots, sought their nourishment at such depths, that they were practically beyond the reach of suffering from a temporary drought.

The value of land is high. There are vast stretches of fine land in the hands of Government, but it might as well be swamp-land for any value it is to investors. Government are willing to lease out grants of 500 acres to *bona fide* cultivators, but there is always that abominable forest clause, which prevents any but idiots from taking up a grant. The forest clause reserves all timber on a grant to the department, so that the lessee cannot cut a tree, and must plant his tea under the densest shade. Again, to the department is reserved the right of felling and removing the timber, without being liable to compensation for injury done by the process. It will be seen from this that leasing waste land is out of the question. The land under forest reservation is about 600 square miles, much of which is suitable for tea, and with the advantages which tea planters enjoy in the Doon, a large portion of this would speedily be put under tea, if the "dog-and-manger" policy of the Government were only departed from.

Now that the rage for "rasp" has somewhat abated, we look for an increase in the value of the teas grown in Upper India. For years back these teas have ranked low in public estimation, solely because the jat of plant, and particularly the climate, made it impossible to manufacture "rasp" to order. This was a disadvantage to the proprietors of the gardens in Kumaon, Dehra Doon, and the Kangra Valley, and their teas were little esteemed in Calcutta. The planters, however, had the satisfaction of knowing that their teas were good and wholesome, and that they did not require to be diluted with China Congou to neutralize the drug-like flavor of the "rasp." Now, however, that we are returning to our proper senses, and are looking out for Indian tea intended and fit to be drunk pure and unmixed, the delicate flavour of the teas of Hindustan, will unfallingly improve in value. For a long series of years, the shares of those companies have been quoted at a considerable discount, and although some of them made fair dividends, the want of sympathy with the Calcutta market has kept down the value of the shares; a revival in demand will however speedily remedy this, and we may soon hope to see those gardens becoming valuable properties.—*Indigo Planters' Gazette.*

† N. B.—ED.

ON COFFFE LEAF DISEASE.

(*Quarterly Journal of Microscopical Science*, January 1882.)

On the MORPHOLOGY *of* HEMILEIA VASTATRIX, Berk. and Br. (*the* FUNGUS *of the* COFFEE DISEASE *of* CEYLON). By H. MARSHALL WARD, B.A., on special duty as Cryptogamist to the Ceylon Government. (With Plates I, II, III.)

[The paper is strictly scientific, but we think it well to publish it, so that all the information possible on the subject of the deadly coffee fungus may be available. It appears that *bacteria* complete the destruction commenced by *Hemileia vastatrix*, and that both Abbay and Morris mistook for developments of the leaf fungus organisms which had no connection with it.—ED.]

During the past twelve months the progress of my investigations into the life history of *Hemileia vastatrix*, the fungus so prominent in the so-called "coffee leaf disease" of Ceylon, has resulted in the accumulation of a series of facts concerning its structure and development which have been hitherto undiscovered, or, in some cases, misunderstood. Sufficient material being now at hand to throw light upon the morphology of this remarkable parasite, I purpose bringing together shortly the main points which have been established.*

Since it is not intended to enter upon any speculations, and none of the numerous physiological and pathological phenomena of "leaf disease" can be introduced here, it appears unnecessary to discuss at length the previous publications on the subject of "coffee-leaf disease."† In so shortly referring to them no inattention is implied, but it will be impossible to clear up points of difference without numerous figures in addition to those hereto annexed. Nor is it necessary to enlarge upon the history, so far known, of this serious pest to one of our most important cultivations. I shall therefore proceed at once to the immediate object of the present paper.

The external appearance of a leaf severely affected with the "disease" is characterised as follows:—Small, cloudy yellow spots appear on the under side of the leaf; any one of these may be observed to increase in area and depth of colour, spreading centrifugally from a point in a more or less circular manner. Sections of such a spot show that a young mycelium is spreading in the lacunæ between the cells of the leaf, and that the discoloured are corresponds to that occupied by the mycelium. In a few days small groups of orange-coloured, granular bodies, appear externally, and, rapidly increasing in numbers, soon form an orange-red powder on the under side of the leaf; this pulverulent "rust" consists of the *spores*‡ developed by the internal mycelium. They arise in rosette-like groups from the stomata to which the mycelial branches have direct access from within. As age progresses the yellow colour of the "disease patch" becomes darker, and at length brown in the centre; the brown colour, which is due to destroyed leaf cells, &c., spreads centrifugally as before, and at length a shrivelled, dark-brown blotch of dead tissue is all that remains of the affected area.

This is the typical mode of development of the "disease spot," and there are several points of importance regarding it. The oldest part is always the centre, and

* Mr. Marshall Ward has reviewed the whole course of his investigations, especially in relation to the economic aspect of the subject, and the possibility of remedial measures, in a final report to the Ceylon Government (Colombo, Sessional Paper XVII, 1881).—[ED. 'Q. J. M. S.']

† They are chiefly—*Abbay*, 'Journ. Linn. Soc.,' Dec., 1878; *Morris*, 'Journ. Linn. Soc.,' March, 1880; and a valuable summary of the whole question up to 1880, by *W. T. Thiselton Dyer*, 'Quart. Journ. of Mic. Sci.,' April, 1880. Smaller papers by Cooke, Berkeley, Thwaites and Morris, are referred to in these.

‡ The evidence which proves this will be found below.

as we proceed outwards from this, each successive phase is younger than the last. The oldest part appears to be always on the *under* side of the leaf; the discoloration of the upper side and the corresponding appearance of the mycelium there occur later. The appearance of various saprophytic fungi on the old shrivelled spot indicates the completion of the destruction. With these and other phenomena which vary the described course of the "disease spot" we are not at present concerned.

The orange-coloured "rust" consists chiefly of small, somewhat reniform bodies, which, from their structure, behaviour towards reagents, &c., and especially from their manner of germination, I have called *Uredospores*, to distinguish them from a second, less common, napiform spore, which presents sufficient analogies to the typical *Teleutospore** of the *Uredineæ* to warrant the adoption of that name also.

The "Teleutospores" were discovered in Ceylon in March, 1880;† they occur mingled with the much more numerous Uredospores on the same "rust" patch, and, indeed, spring from the same spore-group. Mr. Abbay seems to have incompletely figured similar bodies, without understanding their nature, on coffee from Sumatra.‡ Such are, shortly, the external features of the "disease spot," and we may now pass on to the details of form and structure of the parasite itself.

Since the main facts of development are now discovered, it will be perhaps the simplest plan to trace the history of the adult fungus from the *Uredospore*—to relate, in fact, what occurs after sowing the spores on coffee, giving the details of structure as we proceed.

The *Uredospore* ("Sporange" of Abbay and Morris) is figured on Plate I, fig. 1, in various positions, and is seen to be a somewhat kidney-shaped body, broader, and rounded at the free end, and slightly tapering at the other, where it is attached by a very short pedicel to the spore-bearing structure hereafter described (Pl. III, fig. 40, *c* and *f*). The free upper surface is convex from before backwards and from side to side, and is studded with small solid papillæ. The remainder of the surface forms two converging, slightly flattened sides, which gradually meet below in a broad, rounded, saddle-like ridge. This is quite smooth, concave from before backwards, and convex from side to side. The vertical transverse section of such a body is somewhat triangular, with rounded corners; but various figures are obtained by projecting the several oblique optical sections as it rolls over (Pl. I, figs. 1-3). The upper side alone is normally ornamented, though the papillæ at times occur on the upper portions of the otherwise smooth sides; these papillæ are outgrowths of the thick *exospore*, and are usually pointed and regularly distributed on its free surface (fig. 6 *d*).

The granular protoplasmic contents of the spore are enclosed by a delicate hyaline *endospore*, which becomes readily seen on germination, or may be detected by such reagents as sodic-chloride, sugar solution, &c. (figs. 6 and 7), which cause it to contract away from the exospore, to the inner surface of which it was before applied (fig. 4). The contents are usually coloured orange red, and at times contain oil drops of an intense orange-red tint (fig. 5); as a rule, however, the granular matrix is uniform throughout in the fresh spore. Under certain conditions the orange tinge is lost, and the contents of the spore become grey and cloudy. With these and other abnormal changes we are not here concerned. The size of these Uredospores averages $\frac{1}{600}$ inch long by $\frac{1}{900}$ broad and deep.

After lying in water for some hours it commonly happens that many of these spores become filled with spherical vacuoles, closely packed in the granular matrix, of equal or unequal size, and varying in number accordingly. A common appearance is that figured in fig. 7, and the impression of a sac filled with spore-like bodies is suggested. These spherical bodies are, however, not solid, but cavities excavated, so to speak, in the protoplasm, and filled with watery liquid. In the first place they are not constant, but may be seen to change their position, size, &c., very slowly; moreover, they eventually disappear, not by escaping bodily from the sac, but slowly, and this is accompanied by other changes. On crushing the whole carefully, these spheres are no longer seen in the extruded mass of protoplasm. Staining reagents do not colour them darker than the matrix, and they are not rendered clearer by such fluids as would cause contraction of denser protoplasm; on the contrary, solutions of sugar, salt, &c., and such reagents as iodine, glycerine, &c., make them disappear, evidently by the abstraction of water.

With careful treatment I have caused these vacuoles to reappear, after applying weak sugar solution, on washing in pure water. What is the nature of this vacuolisation? How far is it normal, and how far connected with other phenomena, must be left for future consideration. The proofs that these bodies are vacuoles must, however, I think, be admitted.

The strongest evidence that the papillate body is itself a spore, however, and the basis on which I have chiefly proceeded, is afforded by its germination. This occurs in pure water on glass typically as follows. At about two to five, frequently three nearly equidistant spots, the exospore becomes thinner, and pushed aside by the swelling endospore, and a delicate finger-like tube is protruded from each (fig. 8). This tube has very thin cellulose walls and a blunt, rounded apex. It may dilate slightly just beyond the place of exit, and the constriction at that spot is rendered conspicuous in contrast; otherwise the diameter of the tube is equal, and measures about one fifth of the narrow diameter of the spore (fig. 9). This germinal tube rapidly grows forwards, extending, by apical growth, as a simple unbranched cylinder for some time. As it elongates its diameter remains uniform, and its cavity continuous with that of the spore. The orange-coloured granular spore-contents meanwhile pass along the germinal tube, often presenting a most beautiful streaming motion here and there along their course; vacuoles and oil drops form both in spore and tube, and branches are soon put forth at various points, to remain short or become extended, in the same manner as before (fig. 9). This process is, however, limited, and the amount of growth is clearly dependent upon the quantity of food material originally present in the spore.*

After growing thus for some time with a sinuous course and uniform diameter the germinal tube dilates, at some place, usually near the growing end, into an ovoid or pyriform sac-like vesicle, into which all, or nearly all, the coloured contents soon pass (figs. 12 and 13), leaving the rest of the tube and spore empty of everything, except a few granules and frothy vacuoles. Fig. 11 *f* shows in outline what an extensive growth may take place before this sacculation occurs; it usually occurs sooner, however.

The pyriform dilation may remain simple, or put forth branching processes here and there from any point (fig. 14. Sometimes it grows forwards as a simple tube (fig. 15), on which a similar dilatation may arise afterwards, and in this case the coloured contents pass forwards into the new vesicle. This forward growth is very rapid, and accompanied by vigorous streaming of the protoplasmic contents. It sometimes happens that a septum is formed across the neck of this swelling between it and the rest of the tube (fig. 14).

Where the branching is vigorous these vesicular bodies may become very complicated, and assume the most grotesque figures; huge vacuoles, streaming, &c., arise as the growth continues (fig. 14). This is not for long, however, and though the swellings may remain some hours after the remainder of the tube and spore have rotted, they and their contents become at length the prey of Bacteria, Torulæ, &c.

On sowing the Uredospores on the lower surface of vigorous living coffee leaves, I obtained results in the main similar. The germinal tubes produced, however, are usually shorter and less branched, or quite simple, and the whole process is apparently carried on more energetically.

At fig. 16 is represented a piece of the lower epidermis of a cotyledon of *Coffea Arabica*, on which Uredospores had been sown some eighty hours; the spores germinated and put forth the tubes freely as described above. The

* *Vide* 'Second Report to the Ceylon Government,' 1, 1880.

† *Vide* 'Preliminary Report to Ceylon Government,' June, 1880.

‡ Loc. cit., Pl. 13, figs. 10, 11 and 12.

* Attempts to grow a more extensive mycelium in nutritive fluids of various kinds have utterly failed; this is not surprising in the light of what follows.

pyriform vesicle appears very early, and receives the whole of the contents. And now the meaning of the vesicular swelling above described becomes clearer, for it is usually formed over the orifice of a stoma and sends its processes through this into the intercellular spaces of the leaf (Pl. II, fig. 18). This is, in fact, the act of "infection." The Uredospore on germinating produces a simple mycelium (the germinal tube), which grows rapidly at the expense of the reserve material in the spore, and is only capable of further progress on reaching the interior of the leaf in this manner.

The commencement of this further development is well shown in figs. 19 and 20. That the internal mycelium is simply an extension of the germinal tube is proved by such example as fig. 21: the spore germinating close to the orifice of a stoma, has sent its tube directly through into the leaf without forming the preliminary vesicle. These and many similar preparations were obtained by sowing spores on living leaves kept damp in glass cells, and cutting vertical sections at periods varying from 24 to 100 hours afterwards.

I carried still further the proof of the fact that the internal mycelium is but an extension in the leaf of the germinal tube by sowing spores on the *upper* surface of leaves at places from which the epidermis had been removed; the result was a rapid growth of the germinal tube directly into the tissues, pushing its way between the palisade cells as it advanced (figs. 22 and 23). Here again no vesicle was formed. All attempts to infect by sowing on the uninjured upper surface have failed; the spores germinate, tubes and vesicular swellings form as on glass, but the whole soon shrivels and dies.

The mycelium within the leaf, then, the action and extension of which corresponds to the yellow discoloration seen externally, is clearly but a continuation of the germinal tube sent forth from the *Uredospore*, and which enters a stoma as described. Once established in the lacunæ of the leaf this soon branches, chiefly at first in the plane of the leaf, and feeding upon the products of the cells of its host, produces the injury.* At first the young mycelial tubes are very delicate, filled with fine-grained protoplasm, and somewhat stumpy; they soon become vacuolated, and more coarsely granular, and send out tufts of short, thick branches towards the cells bounding the intercellular spaces, while here and there longer "leaders" run out between the cells in various directions.

The main features of the internal mycelium thus produced are typically as follows. Its ramifications are confined to the intercellular spaces (fig. 24), except that at numerous points here and there very slender processes pierce the cell-walls to form haustoria. The mode of branching is extremely irregular, and influenced by the arrangement of the cells between which the branches run; the rate of growth, depending on several circumstances, also affects the length of the branches.

Transverse septa occur here and there, often separated by long intervals (fig. 28), especially at the peripheral parts. The diameter of a mycelial thread is about the same as that of the germinal tube, and, like that, generally preserves its uniform calibre throughout. In some cases the similarity between mycelium and germinal tube is rendered more striking from the contents of the former being also coloured orange-red; as a rule, however, the protoplasm of the internal mycelium is colourless. Vacuoles, granules, and oily drops occur commonly in fresh preparations (fig. 27), but in some cases the branch is filled with a dense, homogeneous protoplasm, shining with a grey, pearly lustre, (fig. 26). The "coral-like" habit of the tufted, short-branched form is well seen in figs. 25 and 28.

The *haustorium* is a somewhat remarkable structure. It consists of a stiff, long neck, piercing the cell wall vertically from a branch of the mycelium (figs. 25, 29, 30); the distal end is expanded into an ovoid or pyriform body, suspended free in the cell cavity, and containing usually one or two brilliant granules surrounded by a cloudy matrix. In older specimens a distinct wall is evident. Spreading in all directions from the point of entry, the mycelial branches become applied to the exterior of the cells, and feed upon their contents by means of these haustoria, until a stage is reached when the well-nourished vegetative structure commences to form the spores, which appear externally as "rust."

This process is begun by a tuft of branches collecting in a lacuna, and growing towards the orifice of the stoma, close to which their apices remain in contact for a short time; the tightly-packed bundle then forces itself into the orifice, and pushes the common apex through to the exterior (figs. 32 and 33), where the spores are formed by budding.

The first spores arise as follows:—The spore-bearing branches, formed as above described, are filled with fine-grained grey protoplasm (fig. 33), and on reaching the exterior the apex of each expands into an ovoid sac (Pl. III, fig. 34), in which the protoplasm accumulates. A succession of other similar sacs arise by budding from the parts below this, and thus a tuft of young spores is formed (fig. 35 and fig. 40 *a*, *b*, *c*). Each of these spores arises by the protrusion of an ovoid sac, remaining narrow below, and becoming constricted off at the neck, where a septum also is formed separating the young spore from the spore-bearing branch (fig. 40). A small pedicel or stalk is usually formed, but the spore is readily detached from this, and it is rarely seen on adult specimens, though the circular place of attachment may frequently be detected.

Each spore consists at first of a simple, smooth, thin-walled sac, filled with fine-grained protoplasm, in which a nucleus-like body may be frequently observed (fig. 40, *c* and *e*). At a very early stage the existence of an endospore can be proved, but the exposure remains smooth and thin for some time. As the regular ovoid shape of the spore becomes altered by lateral and other pressures, the thickening exospore develops the solid papillæ above, and the contents begin to assume the orange-red tinge.

As the spore-bearing branches (each of which forms spores as above at first) pass through the orifice of the stoma they are crowded together into a neck; below and above this constriction they expand again. As age advances, however, they are found to become coalesced into a kind of pseudo-parenchyma, and the later-formed spores arise from the sides and top of a compound body (figs. 39 and 40 *d*), produced by their union. This structure presents the form of an oval boss, with its lower side attached by a neck, which passes through the stoma to the mycelium within the leaf; its sloping sides are covered with crowds of short, stumpy processes (fig. 41), the remains of pedicels from which spores have fallen. The fusion of mycelial elements may even extend to the internal position close to the neck, and possibly the "dark body" figured by Abbay* is this structure, into which air had penetrated.

Viewed from above, the various stages of spore formation are easily discovered. The story is the same. A few ovoid young spores arise (fig. 41 *a*, *b*), and additional ones bud off from near their bases (*c*), until a rosette-like cluster is formed (*e*). The appearance of the old spore-bearing head, formed by the fusion of the spore-bearing branches, is figured at fig. 41 *f*. When the "disease spot" has ceased to spread, and all, or nearly all, the spore-bearing heads have become as advanced as this, the second form of spore is produced.

This *Teleutospore* is a very remarkable body, and it is only intended here to describe its morphological characteristics. It is at first indistinguishable from the young *Uredospore*, but, instead of developing into the reniform papillate structure, it remains somewhat smaller, quite smooth, and expands into a subglobular shape. When fully formed it is napiform, and situated on a short stalk (fig. 44) attached to the spore-bearing head already described (figs. 38 and 39). An endospore is early distinguishable, and the granular protoplasmic contents soon become coloured bright orange red.

Very soon after its complete formation the central portion of the free, slightly flattened end of the oblate spheroid protrudes as a rounded, blunt, boss-like eminence; this

* As further evidence, I may remark the success of infection experiments based on these observations. In one instance, I made sixteen separate sowings on healthy leaves of as many plants: *in fifteen cases* the "disease spot" appeared *where the sowing was made, and nowhere else on the plant*.

* Loc. cit., p. 177, Plate 13, fig. 4, &c.

goes on until the whole structure assumes the shape of a flask (fig. 39). This outgrowth of the apex is the first indication of germination, and the free, straight, neck-like portion is the promycelium. The whole process normally advances to completion, while the Teleutospore is still attached to the spore-bearing head, though detached specimens germinate quite readily in water on glass slips.

When the promycelial tube has attained a length of about six to eight times that of the Teleutospore, it becomes divided by transverse septa into four subequal cells figs. 42—45), each of which receives its share of the orange-coloured contents, which have passed along the tube from the spore. In specimens grown on glass slips under cover the promycelium and chambers are much longer (figs. 45, &c.) than those found on the leaves, and the tube may be curved and delicate in the former case, whereas in the latter the promycelium stands up stiff and straight into the moist atmosphere. This may be compared with what occurs with Uredospores germinating on glass and leaves.

The Promycelium fully formed, each of the four cells (normally) sends forth a slender process, into the cavity of which the coloured contents pass (fig. 45); the process from the upper cell is simply a continuation of its apex; those from the sides of the lower cells spring from beneath the septa. The free terminal portion of each of these four outgrowths now swells into the form of a small subglobular *conidium*, which receives the remaining contents, and at last is simply attached by one point to the constricted end of the branch which produced it (figs. 42—46), and may be detached with the greatest ease.

This *conidium*, abstricted in this manner from the promycelium, is much smaller than the *Teleutospore;* it is usually subglobular, but at times subreniform or ovoid in shape, and is filled with the usual orange-red, granular protoplasm (fig. 46), enclosed in a delicate, smooth envelope. During the formation of the structures just described—*i.e.* during the later stages of its germination—the walls of the Teleutospore and promycelium become collapsed (figs. 42—46, &c.), and, being very transparent, are not easily discovered.

The *Conidia* germinate readily in water (and, indeed, even while attached to the promycelium), and may produce a long delicate tube (fig. 46 *d*) very rapidly; as a rule, however, after forming a large central vacuole, the endospore protrudes slowly (fig. 46 *a*) as a blunt, thin-walled, finger-like process, which attains a length of some four times the diameter of the conidium, and then shrivels up and dies. This very simple and transient germination is all I have been able to induce, either on glass or living leaves.

The production of Teleutospores, &c., appears to be the last act of the mycelium within the leaf, and the brown, shrivelled remains of the "disease patch" soon becomes the prey of Bacteria, &c., which follow in the tracts of such parasites as Hemileia.

The foregoing description will naturally provoke the inquiry, to what group of fungi does Hemileia belong? Without insisting upon an answer to this question, I think it may be worth while to review some of the points in this connection. The general similarity of the "disease-spot" itself to the spots produced by many *Uredineæ* is somewhat striking, and the occurence of the orange-red pigment in all the spore-structures, &c., vividly recalls the same. The mycelium, ramifying in the lacuna and forming tufted groups here and there externally; the septa, sometimes separated by long intervals, sometimes more closely arranged; and again, the centrifugal spread of the fungus, are all points of analogy worth recording.

It seems impossible to overlook the resemblances of the two spores of Hemileia to the *Uredospores* and *Teleutospores* of an ordinary Uredine. In size, colour, ornamentation of the exospore, mode of germination, and entry of the germinal tube through the stoma after forming a vesicular swelling over its orifice, we have strong analogies, so far as the papillate spore is concerned.

The smooth, turnip-shaped spore, in its mode and time of origin, shape, structure and colour, and especially in its germination, so strongly recalls the *Uredinea*, that I ventured to use the well known name Teleutospore. Indeed, the promycelium, with its four cells and conidia, might almost pass for that of *Uromyces* for instance.

Nevertheless, there are some difficulties in referring Hemileia to the ordinary Uredines. The curious spore-bearing head which protrudes through the stoma, and the long-necked haustoria, so numerous on the mycelium, are perhaps the chief. How much weight these difficulties carry may be an open question. In cases where two spore-bearing heads have passed through two closely adjacent stomata, it rarely occurs that the one or two intervening cells have become destroyed; the two heads here become one common, broad, and irregular receptacle, and very like an ordinary uredinous patch.

In conclusion, it appears necessary to make a few remarks on the other forms of fungi, believed by Messrs. Abbay and Morris to be phases in the life-history of *Hemileia vastatrix*. It is impossible to explain all the points raised without numerous drawings, for which there is not room here; at a future date I hope to illustrate more fully the following brief statements.

The forms figured by Abbay* are very common in germination experiments out here. I recognised them at an early date, cultivated them for several months, and through several generations; they produce mycelia and forms of fructification and spores, &c., which have nothing to do with Hemileia. Their connection with the spores of the latter fungus is not genetic. So with the forms illustrated by Morris; † they belong to saprophytic or epiphyllous forms, and can in no way be genetically connected with Hemileia. Of course in such statements I am not resting on the negative evidence that no connection has been traced, but upon the results of actual cultivation of these forms, as well as the successful propagation of Hemileia itself as above described.

May 1st, 1881.

BUFFALO HORN MANURE.—The invigorating and sustaining properties of horn shavings as a manure is being forcibly illustrated at Chiswick in the case of zonal Pelargoniums and tuberous-rooted Begonias in pots. The wonderful wealth of foliage allied to a sturdy growth seen in the plants, and the splendid trusses of flower seen on the Pelargoniums are correct indications of the value of the manure. Chrysanthemums grown in soil with which the horn shavings have been mixed grow vigorously, and retain their foliage to the last. The pity is, that the high price charged for it makes its general us too expensive to plant growers. If the price could be cheapened, the vendors would do a larger and doubtless equally remunerative trade. It should be used only with quick-growing succulent plants; or, at least, with great care in the case of slower growing subjects. Its value is probably mainly due to the ammonia it contains.—*Gardeners' Chronicle.*

LONDON TEA CHARGES.—The *Produce Markets' Review* is very properly heading a crusade against the excessive charges to which importers are liable on tea at the various docks in London. It is shown from a table prepared that the gross charge per chest is 2*s.* 6*d.*, but this is not all. The unnecessary formalities insisted on, mean vexation and loss of valuable time. The imports of tea into England last year were 94,000 tons, and the *Review* says that if the importers had paid the same rate upon tea as is paid on coffee, they would have saved a sum of £100,000, or about two-thirds of what they now pay. It seems truly monstrous that tea should be thus handicapped at home as against coffee. We fancy few will disagree with the following sensible remarks:—In the abstract, there is not the slighest reason why tea should pay more than coffee. No doubt the former is more perishable, but then it is packed in wood and lead, and is thus very fully protected. Nor will the *ad valorem* test explain matters, for the average value of China tea, at any rate, does not now exceed the cost of coffee. Tea, also, is often opened for inspection, but, on the other hand, all coffee is turned out of the packages, bulked, and repacked. Coffee and tea alike are sold at landing weights and numbers, and there is no special difference between the weight of a bag of coffee and of a chest of tea.—*Indian Tea Gazette.*

INSECTS INJURIOUS TO FOREST AND SHADE TREES.

By A. S. Packard, Jun., M. D. Bulletin No. 7 of the United States Entomological Commission. (Washington: Government Printing Office, 1881.) Pp. 275. 8vo.

We think it might have been better had the author somewhat modified the title. Every insect known to feed upon a particular tree is treated upon. In his introductory remarks the author states that Kaltenbach enumerates 537 species of insects as injurous to the "Oak" in Europe; a very large number are given as injurious to the same tree (using the term in a broad sense) in America. It is obvious, when we come to analyse this list, that only a very small proportion of these are strictly noxious insects, and then only when they occur in extraordinary numbers, which is only occasionally. It is natural for certain caterpillars to feed upon certain plants, and the damage they occasion is in proportion to their number. We have to deal here only with trees, and beyond the unsightliness caused by occasional destruction of foliage on a large scale, we doubt if the trees suffer permanent injury from leaf-feeding larvæ. Naturally a certain amount of functional disturbance must result; but surely an equal or greater disturbance arises from judicious pruning or lopping, even although this is usually carried out at the season of least functional activity. Our author, however, regards these insects as "parasites," not specially injurious, adding that the deadly forms are comparatively few. Probably under this latter limited class he includes some of the wood or bark feeders. He is possibly right in some instances, but we feel sure that the morbid conditions commonly attributed to the presence of lignivorous insects are more frequently due, in the first instance, to "something wrong at the root," inducing an unhealthy state which the insects seize upon just as flies attack carriou, or visit an ulcer on a beast's back.

At this moment a lady (Miss E. Ormerod), eminently qualified for the position, has received the distinction of being appointed honorary entomological referee to the Royal Agricultural Society—the first time that economic entomology has received any official recognition in this country. She can, and doubtless will, do much good (as she has already done) in enlightening our agricultural classes as to the nature of the insect pests that trouble them, and by instilling into their minds the axiom that "prevention is better than cure." Keep up a vigorous state of health, and the damage caused by insects will occasion little anxiety as a rule, and to this end the advice of an economic entomologist should mainly be directed. But there are exceptions, and when these assert themselves in an extraordinary degree (as will sometimes happen) we fear the only thing is "to grin and bear them."—*Gardeners' Chronicle.*

INSECTS.

When Shakspeare penned those trite and true words, "The worst of creatures fastest propagate," he must, one would think, have known something of gardeners' troubles, and of the insects with which they have to contend, for truly the rate of increase of some of these is marvellous, and where they spring from, or how many of them originate, is a mystery. Take red-spiders, for instance, the most minute of the lot, and the puzzle is how such pests get into a quite new house freshly planted with Vines or Peaches, and yet, if the conditions are favourable, hosts of them soon come into existence and spread with the greatest rapidity. Bad as red spiders are, however, they are quite outdone by green-fly, which breed so fast as to almost outrun all calculation, and if one or two only appear on a plant, their progeny, and those issuing from them, are soon all over the leaves, sucking out the juices and curling them up. What they have a special liking for just now are Roses and Peaches, which both show unmistakable signs that the enemy is at work, for, look where one will, crippled shoots are to be seen, and if these are not liberated and set going at once, they will be a long time in getting over the check. Tobacco-dust, though highly dangerous to leave on for any lengthened period, is an excellent remedy against aphis, as with a distributor, which may be carried in the pocket while disbudding is going on, a puff may be given to any shoot affected, and the progress and breeding of the insects at once stopped. The best time, however, to apply the tobacco-powder is early in the morning, while the trees or bushes are moist with dew, as then it adheres readily, and as it at once acts on the fly, and causes them to leave their hold, they may easily be washed off by means of water from a garden engine or syringe. By looking over Peaches and Nectarines occasionally and treating them in the way referred to, they may be kept clean without having recourse to Gishurst or other insecticides of a similar nature, none of which can be used while the fruit is in such a small tender state without much risk of injury to the delicate skin. To make short work of greenfly on Roses and cleanse the plants of their presence, there is nothing I am acquainted with equal to nicotine soap, which has the active properties of Tobacco in it, and by diluting it to the proper strength it may be syringed on, or the long shoots bent down and dipped in without causing much waste. Quassia chips boiled with some soft-soap in the water forms a good and cheap insecticide, and if a little tobacco-juice or nicotine is added, fly quickly vanish under its influence. The only way of dealing effectually with the Rose-maggot, so snugly ensconced in the leaves it so dexterously curls, is to give each a loving squeeze between the finger and thumb, which may be done without bruising or harming the young tender foliage, as the grub is soft and collapses under the gentlest of pressure. The Gooseberry caterpillar, so prevalent in some gardens, may be got rid of by the use of lime, which should be sown thickly on the ground under the bushes, as there the larvæ lie and hatch and issue forth as soon as the weather gets warm. Currants, so subject to greenfly, which affect the tips of the young branches, are best managed by nipping the points out, as the aphis cannot exist on the old hardened leaves, the tissues of which are too tough for them to get the sap through. The worst of all the aphis family are the black, which usually affect Cherries, and the only way of destroying them without harming the shoots is to use a strong solution of nicotine soap and immerse them all in. The liquid at once penetrates their oily coating, and by its quick action seems to dissolve them. The aphis peculiar to Plums are almost as difficult to kill, and the best way of battling with these and the black on dessert Cherries is to remove the young shoots early by timely stopping, as by doing this they may in many cases be kept away altogether. As to red-spider, the best remedy where they affect trees on open walls is cold water, drenchings of which from a garden engine they cannot endure. Dryness at the root is a frequent cause of these parasites affecting Peaches, to prevent which it is a good plan to mulch all trees with half-rotten manure, and this should be done early, so as to keep the moisture in and maintain the soil in an equable condition of warmth. By-and-bye, when the fruit is swelling fast, an occasional soaking of sewage will do much towards keeping the trees in vigorous health, and will also assist them greatly in carrying their load.—F. SHEPPARD.—*Gardeners' Chronicle.*

THE ROYAL AGRICULTURAL SOCIETY'S JOURNAL.

The first part of vol. xviii., second series, lately issued, contains matter of great interest, and fully sustains the high character which has been earned for the journal in recent years. The first article is from Rothamsted, and deals with the amount and composition of rain and drainage waters. A great amount of evidence is produced, proving the process of nitrification in the soil, and showing the comparative activity of the action at different seasons. The practical conclusions may be noted. Most of the nitrogen of farm crops is derived from the nitric acid of nitrates within the soil, and this may come from the nitrogenous compounds in the soil itself, from animal and vegetable manures, from the ammonia of artificial manures, and from the ammonia supplied by rain and condensation from the atmosphere. This latter source, however, is very limited. There is a difference in the rapidity with which ammonium salts are converted into nitrates. Thus, the nitrogen of rape cake and farmyard manure is more slowly changed into nitric acid than that from ammonium salts. The nitrogenous compounds of the soil itself are very slowly changed into nitric acid. Where there is no vegetation and drainage in operation, there is a loss of nitric acid by solution from the soil. This loss is greatest during

the winter. When the surface is covered by a crop, as in the case of permanent pasture or clover, then the maximum quantity of nitrogen is absorbed, and the least waste occurs. A very important fact brought out by the experiments at Rothamsted is, that the capacity of a crop to absorb nitrogen depends upon the presence of suitable mineral food, especially potash and phosphoric acid.

We do not entirely receive the Rothamsted experiments as characteristic or illustrative of ordinary cultivated land. The proportion of ammonia is very much greater in the soils at Rothamsted than those under ordinary culture. The drains, as a rule, are only two feet below the surface; nevertheless, they are of great value, as indicating the nature of the changes going on in the soil, and guiding us as to our practice. It is evident that the practice of applying farmyard manure on the stubbles in autumn, once so common on deep good soils, and still practised, is not economical, whereas the dressing of artifical grasses may take place with safety at any time, and the application of manure in spring and summer time for root crops is a safe and sound practice. It is further evident that some loss of nitrogen may occur when our land is clean and uncropped in winter; but we cannot at present go with those who estimate the loss so highly that they would prefer allowing perennial weeds to flourish, and run the risk of not being able to clean the land at all, rather than secure a clean soil with a certain loss of nitrogen. —*Field.*

EXPERIMENTS IN MANURING SANDY SOIL.

SIR,—Will you permit me to call the attention of your readers to the very interesting report just furnished by the Sussex Association for the Improvement of Agriculture? I could wish that a copy of that report were in the hands of every agriculturist; but, as this is impossible, perhaps you will allow me to allude to one or two of the lessons which the experiments of the society appear to teach.

On one of the stations (Hassock's Gate) the society had a soil to work on which was almost pure sand, containing only ·260 per cent of organic matter, and ·458 of soluble ingredients—in fact, almost entirely destitute of plant food; and perhaps I had better leave Mr. Jamieson, the chemist of the association, to describe in his own words the effects of manures upon it: "He would merely say that, when they gave no manure to that sandy soil, the plants never got beyond the first few germinal leaves. When they gave all the ingredients essential to plant life, omitting only the phosphates, they had a little better plant, giving about half a ton per acre; but when they supplied the phosphate in the form in which it had long been said to be of no use, the produce rose to about eighteen or twenty tons per acre. This he thought had given the finishing point to the battle of the phosphates. The form of phosphate he had found to answer best in Sussex was a mixture in two equal parts of finely ground coprolite and steamed bone flour, and this mixture was far more economical than superphosphate or dissolved bones."

Mr. Jamieson goes on to estimate the saving which can be effected by using the more economical manure which was found to answer best in Sussex and in Scotland. He calculates that in the county of Sussex alone the saving would be £35,000 annually. Mr. Jamieson was not content with weighing the produce of each plot of land; but he proceeded to estimate the solid matter contained in the turnips grown by the application of each form of phosphate, and the conclusion was forced upon him that the finely ground undissolved coprolite and steamed bone flour produced a turnip containing less water, and consequently not so liable to rot as that grown by dissolved bones or superphosphate.

I shall not trespass longer on your valuable space, but would say in conclusion that Mr. Jamieson deserves the thanks of every honest chemist by the way in which he has exposed the present system of giving high analyses, whereby a manure is made to appear to contain by analysis far more phosphoric acid than is really present. It is high time this practise was done away with, and it is to be hoped that Mr. Jamieson will succeed in giving the finishing blow to this monstrous evil.—A. M'DONALD GRAHAM, F.C.S., F.I.C., 3, Union-chambers, Union-street, Liverpool. —*Field.*

GYPSUM.

SIR,—Continuing this subject, which has been discussed in your paper from time to time, I send you a translation of an interesting German paper, which puts the question of "fixing carbonate of ammonia by gypsum" on a more scientific basis than heretofore. It needs no comment, except as to its concluding paragraph. With regard to that, in this country at least, gypsum is much cheaper than magnesium chloride; so there is no necessity to risk the poisonous influence credited to an excess of chlorides, even though this alleged pernicious influence is combated by the author. F. C. S.

The following is a translation of a paper (from *Biedermann's Central Blatt*, January, 1882, pages 8, 9, and 10) originally published in the report of the German Stations for Agricultural Experiments, 1881.

ON THE POWER OF SOME SALTS TO "FIX" AMMONIA.

BY DR A. MARKER.

For the purpose of fixing the volatile ammonium carbonate in manures, formerly gypsum, and of late years Stassfurt potassium salts, have been used; but as yet no numerical data have been published on the subject. The author, therefore, has undertaken to fill up this gap. The experiments were tried with gypsum, kainite, kieserite, magnesium sulphate, potassium sulphate, and magnesium chloride.

The questions to be solved were: (1) How much carbonate of ammonia can be fixed, *i. e.*, rendered not volatile, by a given quantity of the substance? for example, by one gram of gypsum, kainite, &c.; or, inversely, how much of the substance would be required to fix one gram of ammonium carbonate? (2) Does the one gram of substance always fix a like quantity of ammonium carbonate, or does the quantity fixed depend upon the amount of ammonium carbonate originally mixed with the gypsum or other substance used?

The method employed was this: Each of the substances was mixed respectively with 10, 20, 30, 50, and 80 per cent ammonium carbonate; they were ground up together in a mortar, moistened with water, and left for twenty-four hours. The unfixed ammonium carbonate was then driven off by heating on a water-bath; the insoluble carbonates were filtered off, the filtrate made up to a definite volume, and the nitrogen estimated by the azotometer. The ammonium carbonate was calculated from the quantity of nitrogen found. The results are tabulated below. The numbers represent the ammonium carbonate fixed for one gram of the substance.

	In the 10 per cent mixture.	In the 20 per cent mixture.	In the 30 per cent mixture.	In the 50 per cent mixture.	In the 80 per cent mixture.
Potassium sulphate ...	0·005 ...	0·008 ...	0·01 ...	0·016 ...	0·031
Gypsum	0·07 ...	0·12 ...	0·21 ...	0·55 ...	0·62
Kainite	0·08 ...	0·09 ...	0·15 ...	0·22 ...	0·25
Kieserite	0·08 ...	0·09 ...	0·13 ...	0·24 ...	0·31
Magnesium sulphate...	0·10 ...	0·20 ...	0·18 ...	0·23 ...	0·23
Magnesium chloride...	0·11 ...	0·22 ...	0·35 ...	0·47 ...	0·42

The quantity of ammonia fixed by these substances —potassium sulphate excepted—is not insignificant, and, in fact, the fixing power of the substance increases, almost throughout, with the amount of ammonium carbonate in the mixture. It is hence probable that the quantity of fixed ammonium carbonate does not depend upon an excess of the fixing substance, but on the larger or smaller number of points of contact between the two substances. Therefore it is advisable in practice, in order to obtain the best effect, to use the fixing substances as finely divided as possible.

It will be seen from the table that, with gypsum, the mixture containing the smallest percentage fixes the least, whilst the mixture with the largest percentage fixes the greatest, quantity of ammonium carbonate. With magnesium sulphate, however, this is not the case; and with kainite, kieserite, and magnesium chloride, the fixing power is nearly the same for all mixtures.

The increase in the fixing power of gypsum evidently shows that, on account of the insolubility of the salt, the very large number of points of contact afford an unlimited requisite for the fixing of a larger quantity of ammonia

The fixing of ammonium carbonate rests solely on a chemical process. The change therefore takes place with greatest perfection when insoluble carbonates are formed. The length of time of action of the salts on one another is of a very small importance, as regards the quantity of ammonia fixed. The following numbers illustrate this fact. They represent the fixed ammonia in percentages of the entire quantity of ammonium carbonate present in the mixture. The mixture was gypsum with 10 per cent of ammonium carbonate:—Immediately, 53·50 per cent; after twenty-four hours, 60·00 per cent; after forty hours, 61·50 per cent; after 120 hours, 74·30 per cent. For practical purposes, we may deduce from these experiments that gypsum and magnesium chloride are by far the most suitable for the prevention of the volatility of ammonium carbonate; but magnesium sulphate, kainite, and kieserite are also useful for this purpose, and, therefore, where they can be obtained easily and cheap, they may be used to advantage. Special attention is due to magnesium chloride, because of its very low price. With regard to the objection that, when magnesium chloride is used, chlorides are added to the soil which are injurious or even poisonous to plant life, the author refers to his work, "Potassium Salts and their Application in Agriculture," where there are facts which show that, in many cases, impure potassium salts (containing chlorine) have produced larger results than the pure salt not containing chlorine.—*Field.*

CULTIVATION OF USEFUL PLANTS IS SAN DOMINGO.

In a recently issued report by Major Stuart on San Domingo it is stated that the cultivation of the Sugar-cane may now be considered an established industry in the district of Porto Plata. There are already five large plantations in bearing, with mills of the most approved construction. The area of many of the old plantations is being enlarged, and new ones are marked out for immediate clearing. The cultivation of the Sugar-cane is, however, ont the only agricultural industry that has lately begun to flourish in this district; Cocoa, Coffee, and Tobacco are also produced in continually increasing quantities, having each a good surplus for exportation after liberally supplying the home trade for local consumption. Previous to the recent introduction of the Sugar-cane, Cocoa, Coffee, and Tobacco formed the staple produce of the country, and its chief medium of commerce. About 12,000 quintals was annually exported, nearly all of which was sent to Bremen, the chief market for the produce of Porto Plata. In 1878 or 1879 the consignees at Bremen wrote to their correspondents in Porto Plata that they would accept no more consignments of Dominican Tobacco, as owing to the want of proper care in the cultivation of the plant, and in the preparation of the leaf, it could not be sold unless at a heavy loss. This announcement produced a widespread consternation in the country, for it seemed to threaten both growers and exporters with ruin. Happily the remedy was at hand. A good many Cubans were in the country who understood the Cuban mode of cultivating and preparing Tobacco; they were applied to by the Dominican growers, and the fruits of their instructions were the exportation from Porto Plata alone of 40,000 quintals in 1880, and 100,000 quintals in 1881, of prime Tobacco.

Dominican Tobacco is now in demand, at good prices, not only in Bremen, but also in Liverpool, Havre, and New York. Its cultivation is carried on in the southern districts, as well as in the north, and on a yearly increasing breadth of land, while both in the north and south factories are already established for the manufacture of cigars and cigarettes under the superintendence of Cubans of experience. Of these manufactures there is already a very considerable exportation, with every prospect of increase. In fact the Dominicans aim at competing with the Cubans in the finer sorts of Tobacco, and as they possess the same advantages of soil and climate, there is no reason why, with equal skill and care, they should not succeed.

Major Stuart further writes as follows:—

"All that I have said about the progress of agriculture in the north applies in every particular to the south, but in a much larger sense as regards Sugar. On the lands lying aback from the capital, and along the banks of the lower Ozama, numerous cane plantations are now established each complete with mill and all the stock and requirements for the production of sugar. There are already twenty-three of these plantations within a radius of a few miles round San Domingo city, and it is not intended that the number should rest there. When I visited San Domingo for the first time, in the fall of 1875, none of these plantations existed, but one—the first in the country—was in course of clearing, and workmen were engaged in putting up the mill. Last year, I may add, a system that promises well was tried of inducing small holders in the neighbourhood of plantations to raise canes on their lands, and sell them in a raw state to the millowners. The cultivation of Coffee is also in a promising condition in the Dominican country. Congenical soil and climate for it are found without difficulty in various places, but chiefly at present on the heights above Azua overlooking the Bay of Ochoa, a deep inlet that divides into nearly equal parts the south coast of the island. Here a small Coffee plantation was established in 1877 by President Gonzalez on his patrimonial lands. It succeeded so well that others hastened to follow the example, not only in the neighbourhood of Azua, but also in different parts of the country. The little tree is tended and dressed with proper care, the berry is treated after the most approved process, and so rapidly has the cultivation extended that even now Dominican Coffee appears in its own name on foreign markets, and is quoted, I have been told, on a par with that of Jamaica. The quantity exported is still comparatively small, but it increases with every season. Until 1878 Coffee was imported into the country, for the Dominicans are a coffee-drinking people, and now it is the surplus left after the supply for home consumption that is sent out of the country."

The next production to be noticed is the Cacao or Chocolate tree. This tree is of recent introduction into the Dominica country. It has taken very kindly to the soil, and, being cultivated with care it yields abundantly, and the kernel is of good quallity. Cacao now figures well among the exports of the country, with an annual increase which keeps pace with that of Sugar and Coffee.—*Gardeners' Chronicle.*

MANURES AS ABSORBENTS OF WATER.

BY A. STEPHEN WILSON.

I am not aware that any complete theory of a manure has yet been laid down; nor I do propose entering upon the labour of laying down such a theory. My present purpose is to show, from experiments made by me, that manures perform a certain office in addition to that of directly supplying plants with the food contained in their own substances. The office to which I refer is that of absorbing moisture from the atmosphere—a function which may be called hygrosorption (*hugros*, moist, and *sorbeo*, I drink up). Now, it would seem obvious that if in a dry season a given manure has the capacity of absorbing moisture from the atmosphere more copiously than the soil in which it is mixed, the roots of plants growing in that soil and manure will be better supplied with water than if the manure were absent. And if, of two manures, the hygrosorptive power of the one is greater than that of the other, a plant growing in the more hygrosorptive will be better supplied with water than a plant growing in the less. But the results will be better seen after the experiments have been detailed.

Some trials of a rough kind were first made in search of suggestions. Two small flower-pots were filled with soil; two were filled with the same soil mixed with finely ground Cambridge coprolite; two with soil and dissolved coprolite; and two with soil and guano. The pots were accurately weighed and set beside each other in the evening in a garden walk. In the morning it was found that the soil alone had gained 47 grains; soil and ground coprolite, 42 grains; soil and dissolved coprolite, 60 grains; and soil with guano, 54 grains. This comparison was carried on for twelve days; but the conditions were seen to be very defective. The pots were of equal size, but possibly varied in porosity. The soil and the manures at the outset were just taken as they came to hand, and therefore may have contained, to being with, varying percentages of moisture; then slight showers occasionally fell, while the wind may have carried off from some of the pots a few particles

lying on the surface The results were, therefore of no value, except to indicate certain precautions necessary to secure scientific facts, and need not be here given.

FIRST SERIES.

Garden soil, ground coprolite, dissolved coprolite (superphosphate), and guano were then taken, and all sun-dried, though not completely. Small stoneware jars, all of the same size and shape, were than filled with as nearly the same degree of compactness as could be attained. They were then set upon a platform in a tray containing water, and the whole enclosed with a large glass bell to confine the evaporation. Weighings were made every day, but as they harmonised throughout only as many are given as to show the general results. From May 28 to June 8 the earth lost 25 parts from 1,000, the ground coprolite gained 14 parts, the dissolved coprolite gained 39 parts, and the guano gained 80 parts. Undoubtedly had the jar of earth stood in the water-closed bell alone it would have gained wieght, but the absorptive power of the dissolved coprolite and guano immediately beside it caused a still further drying of the less absorptive soil; and this result shows that such manures in a comparatively dry soil will attract towards their particles the moisture in the surrounding soil, and therefore become more rapidly liquified and available for roots.

SECOND SERIES.

But the conditions under a glass bell were somewhat artificial. I next thoroughly sun-dried quantities of earth, cow-dung (pulverised), ground coprolite, dissolved coprolite, potato manure, and guano. They were all in a state of fine division. Cups and pans corresponding with each other in size and surface were filled with the various manures, and the surface struck off with a straight-edge. It would have been possible to have put the same weight into the competing jars, but this would have neceissitated different degrees of compression, and it was therefore resolved to compare equal bulks exposed with equal surfaces. The cups were of different sizes, the same numbers (1, 2, 3) in the table being of the same size. The whole were placed in a large tray and set in the floor of a disused milk-house.

Between June 3 and 10 the earth had gained in each cup 2 per cent, the cow-dung 10 per cent, the ground coprolite 3 per cent, the dissolved coprolite 6, 7, and 8 per cent, in the respective cups; the Potato manure 26 per cent in one cup and 35 per cent in the other, and the guano had gained in one cup 10 per cent in another 15, and in the third 19 per cent. The gain is greatest in some of the small pans, simply because the absorbing surface exposed to the air bears a greater proportion to the weight of manure in the pan in the smaller pans than in the larger. Where there is little absorptive force the difference is small.

It is seen from the figures that the earth has less absorbing power for atmospheric moisture than any of the manures compared with it. The next lowest in this power is the ground coprolite, then follows the dissolved coprolite, absorbing twice as much moisture as the ground coprolite; then comes the cow-dung or farmyard manure, absorbing rather more than the dissolved coprolite; next follows the guano, with a still higher absorptive power; and lastly comes the Potato manure, taking in form the air nearly four times as much water as the superphosphate.
